$$\text{Centrifugal force} = \frac{W v^2}{g R} \ldots\ldots\ldots\ldots\ldots\ldots \quad (1)$$

$$\text{Now, } v = \frac{2 \times 3{\cdot}1416 \times R \times N}{60}, \text{ therefore,}$$

$$v^2 = \frac{4 \times 9{\cdot}87 \times R^2 N \times {}^2}{3{,}600} \ldots\ldots\ldots\ldots \quad (2)$$

Substituting (2) for $v^2$ in (1), and working out, we get—

$$\text{Centrifugal force} = \frac{W \times N^2 \times R \times 39{\cdot}4784}{115{,}920}$$

$$= \frac{39{\cdot}4784}{115{,}920} \cdot W N^2 R = {\cdot}00034\, W N^2 R;$$

*i.e.*, the multiplier ·00034 is a constant co-efficient of centrifugal force.—George H. Strong.

[56561.]—**Electric Pen Battery.**—The fault is not originated by the form of battery, but is consequent on the texture of the porous pots or plates. At one time I had several of these in daily use, and I had to find out many wrinkles about them. After thinking the matter over, I laid my ideas before a professional electric-pen printer with whom I was intimately acquainted. His views, founded on a far more extensive use than my own, entirely justified my theory. And this was, that pots too soft or too porous caused the battery to quickly become exhausted; pots too hard, on the other hand, were the cause of a weak current; whilst with pots of a suitable hardness the battery would run for months without more attention than the withdrawal of exhausted solution. If the bichromate fluid turned a purple colour we considered it exhausted, whilst at short intervals we withdrew from the porous pot a small quantity of the solution, displacing it with pure water, thus keeping the sulphate of zinc from reaching too high a density. No doubt your troubles are traceable to the causes I have briefly shadowed forth. At any rate, I do not think you will beat the Fuller cell.—Invicta.

[56563.]—**Medical Coil.**—The terms "positive" and "negative," as applied to currents, are often confusing. They have certainly confused Mr. "Bobadil." Pray do not attempt to reply to queries again before laying well to heart the advice given by Montaigne, which appears every week under "Letters to the Editor." Wherever did you obtain the information you give us?—"Positive electricity is that which leaves the battery by the wire connected with the carbon plate, and negative current that which leaves by the wire connected with the zinc." Dear me! Extraordinary! What do the "positive and negative currents" do when they meet? Pray explain this new theory of yours. How many electricities are there? You already speak of four. Try and discover a few more by next week. It is perfectly astounding that in these days of information anyone who presumes to enlighten others should have written such a farrago of nonsensical rubbish.—C. D. R.

[56566.]—**Iron Moulding.**—Green-sand moulding is the ordinary or plain way of moulding pipes, pillars, girders, plates, wheels, and all cheap castings, as they could not pretend to make the castings named in dry sand for the price usually paid. We generally make such as cylinders, marine pumps, calender bowls, mill rolls, and all castings that want to stand a great strain, or have to be bored and turned; also, we usually cast dry sand on the end, as they are both stronger and cleaner, as the dirt rises to the top. Then we have loam mouldings; this we usually do what we cannot do in sand. For instance, I want to make a pan for a chemical works. I have two boards, but no pattern at all. It is worked from a spindle, and built like a house is built, only with loam instead of mortar. I sometimes think of writing a letter or two on Moulding. For green sand, get fine-ground, soft, yellow stone or scraping of macadamised road and coaldust, horsedung, and part old black sand, grind together and riddle for facing pattern. Dry sand is horsedung and red rock and two spadefuls of coaldust to a barrowful of sand. Loam is red rock, and two spadefuls of clay, and a bucketful of thin clay-water ground up.—Sand Rat.

[56567.]—**Wooden Sink for Dark Room.**—First, get the wood thoroughly dry and free from dirt or grease, and then run over its surface the following mixture:—Heat together in an iron vessel a quantity of brown resin, with a quarter of its weight of beeswax. The ingredients should be constantly stirred, and when thoroughly melted and incorporated, may be applied. It will stand the action of water and most chemicals, but might succumb to the action of turpentine or alcohol left on it.—Faber Fabrum Adjuvet.

[56572.]—**Lathe Mandrels.**—To "A. L."—In view of the able and lengthy discussion of late on the subject of lathe anatomy, I should not have ventured my opiniens had my name not have been mentioned. From my own actual experience of lathes, both of English as well as foreign make, I have had all sorts of mandrels in work. As you ask my opinion on the question of cones, I will give it. And it is this: Cones to be of practical use on an everyday lathe should be fitted so that the maximum of bearing surface be obtained, and beyond this each cone should be so arranged that the wear can be taken up independently. Now the old-fashioned plan of a taper cone, the taper running in the direction of the tail-pin, with a second cone reversed in the back bearing, best fulfils the first requirement—viz., that of ample bearing surface. Now I have had also good practical mandrels with reversed cones, having the taper running exactly reversed, that is to say, the front bearing, or the one next the face-plate, tapering down to, instead of from, the mandrel screw. The mandrel, as you mention, having a second reversed taper formed on it out of its own thickness, and the bearing or bush being made adjustable to move towards the face-place to take up the wear of the second cone, a tail pin in either case taking the end thrust. With a fairly long mandrel, this last form ran well enough; but the limit is soon reached of the taper and length of bearing it is possible to give, and this therefore introduces an element adverse to the plan beyond certain limits. Now, taking your case, I should not hesitate an instant to use an unhardened steel mandrel. In fact it would be the correct thing. Phosphor bronze bearings would, however, need being not too hard. The front bearing I should like a little longer, but the other one is right enough for a lathe the size you name. If you have both cones running the same way, and also towards the tail-pin, you would of course have a collar set up by lock-nuts, or an equivalent to prevent end shake from the tail-pin. This is, of course, a necessity in the plan you suggest. Happy to help you further, if desired.—Invicta.

[56576.]—**Insulators.**—The simplest cement is plaster of Paris; but it is not the best, owing to its property of expanding on setting. A good cement is made of plaster of Paris, Portland cement, and sand. The cement known as Muirhead's is composed of Portland cement and rough sand, of each three parts; smith's ashes and brown resin, of each four parts. Another cement consists of resin and smith's ashes, equal parts of each.—Faber Fabrum Adjuvet.

[56577.]—**Soap.**—So far as I have been able to ascertain, cotton-seed oil is not used in soap-making. It might possibly be used in conjunction with other fatty matter, and with the addition of resin.—Faber Fabrum Adjuvet.

[56578.]—**Electric Bells.**—This, as proposed, would be a rather expensive circuit. For the relays I do not think "Electra" could do better than get one of those sold by advertisers in this journal at about 6s. 6d., as a pattern to work by. The resistance of these relays runs, I believe, to about 40 or 50 ohms. Using the size and length of wire he mentions for the "line," the resistance would be 200 ohms; this, with six relays, would bring the total resistance up to 500 ohms. Less than ten Leclanché cells would not work efficiently through this. The circuit would, I presume, be joined up as for single current Morse with relays, but having the bells substituted for the Morse-inker. No. 28 s.c. wire will do very well for winding the bells. Two or three of the cells could also be utilised for the local (bell) circuit. Query.—Are the bells very large and wanted to give large signals? How would a "closed circuit" without the relays suit? If the querist requires a diagram of the connections he can have it with pleasure.—H. S. Beach.

[56580.]—**Tricycle Pedals.**—Why not put in ordinary iron washers? You do not want the pedals to give with a side motion, and therefore springs are of no use to you. Put in the iron washers until you get a good fit, and renew them when worn. I suppose you lubricate the wearing parts.—C. D. R.

[56580.]—**Tricycle Pedals.**—As an old rider on the three-wheeler, I know exactly what is the trouble. The best way to cure it is to take off the offending pedals, and either braze or solder on the outer end of each a piece of wrought iron or brass, the former preferred. Then carefully fit the pedal to the turned part of the shaft, and all end-shake will disappear. The shoulders of the round part should be, and nearly always are, rounded out. This will make it, of course, necessary to file out the ends of the existing pedals, and the new collar brazed on to fit it nicely. Do you know how to do this and make a good fit?—Invicta.

[56585.]—**Boring for Water.**—Say £1 to £3 per foot for sinking. As to mechanism, had better inquire of Appleby, Tylor, Warner, or Jennings, all of London. There is some variation in prices. See Laxton, &c.—Bream's Buildings.

[56586.]—**Brick-Setting.**—The difference per rod (equal to, say, 4,352 stocks) is £3—say £14 in mortar, and £17 in cement. In place bricks say £2 cheaper. In Kentish gault, or blue Staffordshire, dearer. See Spon, Laxton.—Bream's Buildings.

[56586.]—**Brick-Setting.**—The difference in cost is usually charged at so much per rod. The following will answer what "Ignorant" wants:—Obtain cost of cement per bus., sand per yard, and lime per yard (note that hydraulic lime costs more than the common limes), as as 1 rod of brickwork requires 3 yards sand to 1 yard lime, or 36 bus. cement to 36 bus. sharp sand (if in cement), obtain the difference, and ⅗ will, for all practical purposes, give the difference in cost per bricks laid.—Another Student.

[56589.]—**Cost of Cottage.**—Prices vary according to circumstances; but "O." should not pay more than 2½d. to 3d. per cubic foot for his cottage—*i.e.*, as it will contain roughly 10,000 cubic feet, he should get it thoroughly well built for from £100 to £125.—Another Student.

[56590.]—**Soap for Hard Water.**—There is a soap made for salt-water travellers that might answer for toilet purposes, and Hudson's preparation for households. Inquire of Mr. J. R. Greaves, 60, New Oxford-street, London, W.C. He, from his long experience in the trade, may be best able to offer valuable suggestions.—Bream's Buildings.

[56590.]—**Soap for Hard Water.**—"M. C. H." should soften his water by Clarke's process, thus:—Take one or two pounds of well and freshly-burnt lime, and add to it as much water as it will absorb. This will slake the lime in such a manner that it falls down to a moist powder. Add as much of this powder as will lie on a florin to two gallons of the water; stir, and allow the sediment to settle. By performing the operation in the wash-jug at bed time, the water is clear and ready for use in the morning. If the water does not seem to be sufficiently softened, vary the quantity of lime, until you find the proper proportion, as this varies with the hardness of the water. Too much lime is to be avoided. The lime should be kept in an air-tight tin. Water thus softened is also quite suitable for drinking purposes. Water may also be softened by adding to it liquor ammoniæ, avoiding excess of the reagent. The softened water should not have more than a faint ammeniacal smell.—Chromio.

[56592.]—**Electro-Motor.**—A very good plan for "M." to adopt will be the cross of iron, and then he must have four connections on the spindle so placed that contact is made just when a piece of iron is coming to the pole of mag., and as soon as it reaches it the contact must be broken. It may be done by cutting a piece of brass tube, so that there are four pieces of brass and four hollows (do not cut all the tube), and a little inspection will show how it is to be placed.—F. W. A. Taylor.

[56592.]—**Electro Motor.**—Why not construct a motor such as described in "Ours" on several occasions. What you have is simply a toy. Contact should be made so that it is broken as the armature passes over the poles, and not as you appear to have it. On the other hand, if contact is made when the armature is midway between the poles, each pole will have the same influence upon it in both directions, and it will again become stationary. You must therefore arrange the contact midway between the two points. The same remarks apply whether there be one or a dozen armatures.—C. D. R.

[56593.]—**Roofing Rafters.**—Find how many squares of 100ft. super. each. Multiply length by slant, and the product by two, if both sides of roof are alike; if not, make a separate calculation of each by multiplying the length by slant height, and add the results. It takes 1,200 per M. of Countess 20in. x 10in., to cover 72 square yards; weight about 2 tons. See Spon, Rouse, Laxton.—Bream's Buildings.

[56596.]—**Leaky Dark Slide.**—It depends a deal upon where the leakage occurs. If in the wood (not at the hinges), a piece of thick cloth glued over it on the inside answers well. Cloth will do at the hinges also, if you glue it on so as not to impede their motion. I have mended several dark slides this way.—R. A. R. Bennett.

[56597.]—**New Midland Engines.**—The *Engineer* for Feb. 6th has a double-page engraving of the above engines, with dimensions. Sections are given on page 164, Feb. 27. A working drawing with the No. for May 8th.—E. L. P.

[56597.]—**New Midland Engines.**—In reply to "Iron Horse," he will find in the *Engineer* for Feb. 6th, 1885, a two-page outside view of one of the 1675 class Midland engines; two transverse sections appear in the number for Feb. 27th, and a tracing-paper supplement, containing a longitudinal section and sectional plan is issued with the No. for May 8th, 1885; but this latter is not particularly clear or plain.—W. H. Thurlow.

[56597 & 56598.]—**New Midland and M.S. and L. Engines.**—The M.R. 1675 class and M.S. and L. 500 class were illustrated in *The Engineer* of Feb. 6 and Jan. 2, respectively. The M.S. and L. Co. have 12 engines of the type mentioned—viz., No. 399 (1882) and Nos. 500—510 (1883). Dimensions will be found as above.—R. N. H.

[56598.]—**M.S. and L. Single Engines.**—The principal dimensions of these engines are as follows:—Boiler (Yorkshire iron): Diameter outside, 3ft. 11in.; length of barrel, 11ft. 6in.; thickness of plates, ½in. Firebox shell: length, 5ft. 6in.; width between frames, 4ft. 0½in.; height (front), 6ft. 7⅝in.; height (back), 7ft. 1⅝in. Inside firebox (copper): length inside, 4ft. 10⅞in.; width, 3ft. 5½in.; height (front), 4ft. 11¼in.; height (back), 5ft. 5½in. Tubes: number, 195; diameter, 1⅞in.; length over tube plates, 12ft.; water spaces, ¾in. Heating surface: firebox, 87 sq. ft.; tubes, 1,057 sq. ft.—total, 1,144 sq. ft. Grate area, 17 sq. ft. Cylinders: 17½in. diameter, 26in. stroke; steam ports, 14½in. by 1⅝in.; exhaust port, 14½in. by 3¼in.; centres of cylinders apart, 6ft.; inclination, 1 in 12. Eccentrics: throw, 3⅛in.; diameter, 16in. Connecting-rod centres, 5ft. 7⅝in. Wheels: Diameter of leading and trailing wheels (on tread), 3ft. 8in.; diameter of driving wheels, 7ft. 6in. Wheel base: Leading to driving wheel centres, 7ft. 9in.; driving to trailing wheel centres, 8ft.—total wheel base, 15ft. 9in. Weights: On leading wheels, 11tons 3cwt.; on driving wheels, 17tons 11cwt.; on trailing wheels, 11tons 18cwt.—total, 40tons 12cwt. The leading and trailing axle journals are double-coned, those of driving axle straight. I think the number of engines of the 507 class is 15, but am not quite sure as to this. I hope the above information will give what "Iron Horse" requires.—W. H. Thurlow.

[56601.]—**Building Construction.**—There will not be an examination held under the Science and Art Department until next spring. I advise "A Student" to join a class if possible.—Wm. John Grey, Analytical Chemist, Newcastle-upon-Tyne.

[56601.]—**Building Construction.**—"Student" should, if he has not done so, obtain Rivington's "B.C.," Part 1, and the series of plates published by Spon on this subject (by W. Busbridge, at 7s. 6d. for the 30 bound in one vol.), will assist him considerably; but speaking as one who has passed the exam., "Student" should join one of the classes that are instituted in the winter months; it will enlarge his ideas instead of keeping them in a narrow groove, as it will inevitably do if he studies at home. Of course, it can be done privately, but I would strongly advise "Student" to adopt the course suggested.—Another Student.

[56604.]—**Differential Equation.**—There seems to be a misprint in this query. I presume the equation is meant for $\frac{d^2y}{dx^2} - a\frac{dy}{dx} = 0$. If so, the solution would be $y = c_1 e^{ax} + c_2$. Where $c_1$ and $c_2$ are arbitrary constants, and $e$ is the base of the Napierian logarithms. This may be proved by differentiating the last equation, thus—$\frac{dy}{dx} = c_1 a e^{ax}$. Again differentiating, we get $\frac{d^2y}{dx^2} = c_1 a^2 e^{ax}$, and from these two we get the original equation. "Boole's Differential Equations," edited by Todhunter, is a good book to read (Macmillan and Co.).—M.I.C.E., Bath.

[56607.]—**Lighting with Battery.**—You can light a small 2½ candle-power lamp (Swan or Darton's) with your battery for about three hours at a stretch, if you charge the battery with dilute sulphuric acid (one acid to eight water) in the zinc partition, and a saturated solution of bichromate of potash, to which quarter the bulk of strong sulphuric acid has been added in the carbon partition. Or you may use, instead of this latter mixture, what is known as "crystals for bichromate battery." See also reply 56379.—S. Bottone.

[56610.]—**Alloy for Watch Bearings.**—If "Murano" will look in the *Mechanics' Magazine* for Dec. 4, 1830, he will find a reply to the article he mentions, from the pen of no less a personage than Thomas Earnshaw, which will explain why Mr. Bennet's (not Sir John, I think) alloy never came into use. Mr. Earnshaw says he believes the compound may be good and as proper in all cases as brass; but his object is to guard the public against the belief that any other or a better metal than good brass is at all requisite. No doubt the alloy is a useful one, and easily made with all proportions of either silver, gold, or copper, or all three. Palladium, or an alloy of palladium, is used, or said to be used, for the large graduated circles at many observatories, and very likely for scales on philosophical instruments.—Nun. Dor.

[56614.]—**Trespass.**—If your correspondent "Ento," takes his botanical walks upon other people's property without their consent, he is undoubtedly trespassing, no matter what his object may be. It is always safest and easier to get permission. If, however, this is not first obtained, the proper thing to do, on being charged with trespass, is to admit the trespass, tender 1s. for any damage you may have done, and ask the nearest way off the premises. This is the *legal* thing to do, and may save any amount of trouble, as I have proved. The 1s. is rarely, if ever, taken, and you take the wind out of the owner's sails, if he determines to bring the matter before a magistrate, as you have already offered him compensation for any nominal damage done to his property.—Marcus.

[56614.]—**Trespass.**—How can such a question be asked? Had not the inquirer better have added, in the pursuit of pheasants, diamonds, precious stones, &c., &c.? How is it possible that the object which a man has in view can justify a trespass on another man's land? If such a trespass can be made on land, why not in a house? Say Lord A. has a fine collection of—well anything. Does "Ento" believe that because B. simply wants to look at the collection in the pursuit of knowledge, that he can enter Lord A.'s house and private apartments? If he tried it at my house, he would be turned into the street; and if I had land, and he trespassed with a similar idea, I should treat him as a trespasser.—R. S. T.

[56615.]—**Air Pressure at High Temperatures.**—Keeping the pressure on a given weight of air constant, its volume varies directly as the absolute temperature; and hence, if its volume be kept constant, the pressure will vary in the same way. Thus, a cubic foot of air at zero Centigrade under 15lb. pressure, would exert a pressure of 30lb. if heated to 273° Centigrade. A small correction would have to be made for expansion of the containing vessel if *very* great accuracy was needed.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56616.]—**Greek.**—"L. C." should pronounce all the vowels separately in the first syllables of the Ionic Greek words he mentions; but the upsilon is very slightly sounded. He propably knows that epsilon is pronounced like *a* in baker, and upsilon like *u* in lute.—G. J. W.

[56616.]—**Greek.**—"L. C." asks, how is ωυ to be pronounced in words which occur in Herodotus, &c. If this means, as I suppose it must, How did Herodotus himself pronounce it? it becomes a question of history, and one which it is extremely difficult to answer. We do not knew for certain what ought to be more easily ascertained than the pronunciation of Greek—namely, how Latin is to be pronounced. English scholars are by no means agreed upon this point; and, strange as it may seem, their pronunciation seems mainly to depend upon their religious views. Thus, for some three centuries the way in which the vowels *a*, *e*, *i*, &c., were pronounced by most Englishmen was with the same sound that they would have in English words. Catholics, on the other hand, give them the same sound that they have in Italian words. I was once told by a learned Protestant authority that the reason why Englishmen have diverged from the Italian and also from the usual Continental pronunciation, was the amiable peculiarity so commonly found in controversialists, whether religious or political, of doing everything as differently as they possibly can from what is done by those to whom they have an antipathy. Hence *i*, which formerly had the sound of *e* in the word *we* was made to sound as it does in *nice*. There are excellent scholars who follow each way, as also in the pronunciation of Greek vowels; but if we look to history to get an idea of how such as υ (upsilon) should be pronounced, the best thing to do will be to see what letter was substituted for it when such a word as πρεσβυτερος was Latinised; in early times, when both Greek and Latin were living languages. At school, we were taught that *υ* had always the sound that *eu* has in "deuce." Historically, however, it would seem to have the sound that *y* has in presbyter: as for the diphthong *ωυ* most likely its pronunciation depended upon its surroundings, as does that of *ou* in English. There are five different ways of pronouncing ough, and in Ireland there is yet a sixth, as in the name Colclough, pronounced Cokely.—W. G. P.

[56617.]—**Lighting with Battery.**—The best solution for your batteries consists of, for the porous-pot containing zinc, a semi-saturated solution of common salt in water, and for carbons a solution of bichromate of potash, with a little sulphuric acid added. A very good lamp will be one of the Edison-Swan lamps of about 5-candle-power. —F. W. A. Taylor.

[56618.]—**Salicylic Acid** requires about 1,800 parts of cold water to dissolve it; but in hot water it is much more soluble. It crystallises from its aqueous solution in needles, and from alcohol, by spontaneous evaporation in large monoclinic prisms. —Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56619.]—**Oxyhydrogen Blowpipe — Steel Furnace.**—For small lots of metal, say up to 28lb., I should myself unquestionably use the Fletcher injector furnace, as being the simplest and quickest means. The oxyhydrogen blowpipe is a costly and unsatisfactory mode of dealing with the question. Neither is it suitable for quantities. The cost of oxygen gas would be a very heavy item whilst coal-gas is cheap enough. I am quite sure an injector furnace is by far superior to the blowpipe, as with the latter a furnace would be requisite. And the most simple and suitable form is certainly that used by Mr. Fletcher.—Invicta.

[56620.]—**Steam-Carriage.**—Weight, heat, and smoke, &c., all against steam-engine for common roads. A better motor for such purpose any machinist, with an engineer, could make to work with gas, air, electricity, or even hydraulics, on proper agreement about weights, powers, and price. If near London, "S. R." better see steam-coach at South Kensington Museum; investing in mere scrap-heap building does not pay nowadays.—Drummond Collier.

[56620.] — **Steam - Carriage.**—Before you attempt to construct anything of the sort, ascertain if you will be allowed to use it. Steam carriages would have been an institution years back were it not for the restrictions placed upon them. If "Steam Roadster" is satisfied to use his machine before 6 a.m. and after 6 p.m., and at a rate not exceeding four miles per hour, he may possibly obtain permission to run it on a public highway. If not, he must be content with the means of locomotion he now possesses.—C. D. R.

[56620.]—**Steam - Carriage.**—The restrictions unfairly and unjustly laid on the use of steam on the common roads are so intolerable and vexatious, that I do not think it would be worth your while going into the matter. I will just mention one or two points that will show you the one-sidedness of the law on the subject. For instance, the speed must not exceed four miles an hour, and you must have also a man with a red flag to walk in advance. You must always and instantly stop if a carriage passes and the horse or horses choose to be frightened. Then, again, many of the local authorities in rural districts have a code of by-laws which provide that no steamer shall pass over their roads only during certain hours, usually from 6 or 8 in the evening to a similar hour in the morning; but even then with the farce of the man and red flag and the funeral pace. Beyond this, the subject is surrounded by endless difficulties—difficulties directly traceable to the influence and injustice of those who make our laws, and who make them for themselves and not for us. If any evidence were needed of the injustice and illegal tyranny of the Great Unpaid, let any doubter investigate the doings of some of the Cheshire magistracy, and the mode they adopt as against both bicyclists and tricyclists. That an efficient and satisfactory steam carriage can be produced is undoubted. Any assistance in that direction I would freely give the querist, supposing that he cares to undertake the matter in the face of the facts. Now, supposing I was about to construct such a motor, I should use either three or four wheels, with a vertical boiler, the frame of charcoal iron, and everything reduced to the simplest form possible. Gearing means noise and multiplication of parts. And as before advocated, I should go for direct action; a cylinder, therefore, of small bore and long stroke would be requisite. With coke firing no appreciable amount of smoke need show, whilst the exhaust steam might easily be got rid of without showing. Water and coke are easily carried out of sight, so that difficulties of construction and arrangement are not by any means insuperable. The idea of making it resemble an ordinary brougham is very good; but it means extra weight and resistance, which in time means more engine power. I will give the matter some further consideration, and will, failing anyone else dealing with the subject, fairly give you the result of my ideas.—Invicta.

[56622.]—**Lightning Conductors.**—Don't use insulators. Tape is best, then stout wire rope; tube is bad, except for upper terminals. Area protected is rather doubtful, probably a radius equal to the height; but see "Report of Lightning Rod Conference," published by Spon.—T.

[56622.]—**Lightning Conductors.**—A lightning conductor protects an area inclosed by a circle having a radius = to height × 2; and therefore a conductor 80ft. high would protect an area = to 80 × 2 × 3·1416 × 2ft.—F. W. A. Taylor.

[56622.]—**Lightning Conductors.**—The following precautions must be taken:—1. The top must be well pointed; in fact, it should have a fine sharp point; must be well elevated above any other part of the building. 2. Must have a continuous connection with the ground; should terminate in moist ground, or should have branches from base running into coke. 3. Must not touch pipes supplying the building. 4. Metal roofing should be attached to it. It is not necessary to insulate supports and holdfasts. The tape form is best; if of copper should be at least 0·15in. thick; iron should be at least six times as thick. A conductor 80ft. high will protect a circle of 80ft. radius round the base. The whole space protected is conical, having the circle of 80ft. radius as base.—J. Rance.

[56625.]—**Steam.**—In dealing with problems of this kind it is necessary to obtain an expression for the heat evolved, and another expression for the heat absorbed; by equating these two together the desired result is obtained. In the first case let $t$ = resulting temperature, then $540 + (100 - t)$ = heat evolved by 1lb. of steam at 100° in cooling down to $t$; and obviously the heat absorbed by the water is $11\,t$. Hence $640 - t = 11\,t$, or $12\,t = 640$, and $t = 53\frac{1}{3}°$ Centigrade. In the second case the heat evolved is $\frac{540 + (100 - t)}{3}$, and the heat absorbed is $12\,(t - 20)$; whence—

$$640 - t = 36\,t - 720$$
$$37\,t = 1360$$
$$t = 36\tfrac{28}{37}° \text{ Centigrade.}$$

—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56625.]—**Steam.**—The following is the formula for working problems like yours:—

$$(536 \times W) + [W \times (100 - t)] = W^1\,(t - T).$$

Where W = weight of steam, $W^1$ = weight of water, and $t$ = resulting temp., and T = temp. of water at commencement. Then the workings are—$(536 \times 1) + [1 \times (100 - t)] = 11 \times (t - o) = 536 + 100 - t = 11\,t$.

$$\therefore 12\,t = 636,\ \underline{t = 53° \text{ C.}}$$

And for No. 2—

$$(536 \times \tfrac{1}{3}) + [\tfrac{1}{3}\,(100 - t)] = 12\,t - 12 \times 20 = \frac{536}{3} + \frac{100}{3} - \frac{t}{3} = 12\,t - 240 = 536 + 100 - t = 36\,t - 720;\ 35\,t = 536 + 100 + 720 = 1356\,t = \frac{1356}{35} =$$

38·7° nearly C.—F. W. A. Taylor.

[56625.]—**Steam.**—The number of units of heat given out by 1lb. of water vapour in condensing to water at 0° C. was found by Regnault to be represented by the following formula $606{\cdot}5 + {\cdot}305 \times T$. T is the temperature of the steam C. If the steam is at atmospheric pressure, T will, of course, be 100, and the heat given out in condensing will be $606{\cdot}5 + {\cdot}305 \times 100 = 637$ units of heat (the heat required to raise 1lb. of water 1° C.). In the first problem the 637 units of heat given out by the pound of steam will be divided among the 12lb. of water resulting after its condensation, thus raising its temperature to $\frac{637}{12} = 53{\cdot}083°$ C. In the second case it is clear that a pound of steam condensing at 20° C. instead of at 0° C. will only give out $637 - 20 = 617$ units of heat, and ⅓lb. will therefore give out $\frac{617}{3} = 205{\cdot}66$ units, thus raising the temperature of the whole by $\frac{205{\cdot}66}{12{\cdot}33} = 16{\cdot}675°$. This added to the original temperature gives that of the mixture = 36·675°. If the steam is at a pressure greater or less than one atmosphere, the corresponding value for T must be taken from a table and used instead of 100. For instance, at a pressure of six atmospheres, corresponding to about 75lb. in a steam boiler, T will be 157·02. In the above calculation no allowance is made for variations in the specific heat of water, as it is too small to be of any practical importance. Its tendency is to slightly lower the temperature of the mixture.—G. Jackson.

[56624.]—**Newmarket Direct Railway.**—I walked over the disused portion of this line, about 9 miles, in 1878. It was opened about 1848. It was soon found that a line from Chesterford was a mistake, and, on the opening of the Cambridge extension, its little traffic all vanished. There are three or four rather stiff chalk cuttings, and a good deal of low embankment. Much of the line is planted with trees, which were not very young in 1873. Two of the old stations, of the smallest kind, then existed. One was called Balsham-road, about 3 miles from Six-mile Bottom; the other was 3½ miles further south, and within a few yards of the present Pampisford Station (formerly called Abington), of the G.E R. Haverhill line. Had the latter then existed, the two must have crossed at right angles on the level. For some distance south of this spot the old line has been completely ploughed away. Many of its occupation-bridges have gone. The works are for a double line; but probably it was only single, as east of Six-mile Bottom the line was single down to 1877, or so. I have heard that the Jocky Club subscribed very largely to the "Newmarket Direct."—W. B. P.

[56628.]—**Heliograph.**—If "Magister Artibus" will look at a glass window of a house on a sunshiny day, he will see the principle of the heliograph. The Crystal Palace can be distinguished miles off by the reflection of the sun on the roof. If a cloud obscures the sun, the effect is gone. The heliograph can only be used when the sun is shining. You can obtain the code of signals from the War Department.—C. D. R.

[56628.]—**Heliograph.**—The following is extracted from the "Manual of Instruction in Army Signalling," price 6d., easily obtained through any bookseller. "A mirror is mounted with trunnions in a U-frame fixed to a plate, which moves horizontally on another plate fixed to a tripod stand. A tangent screw working between these plates gives the mirror a slow horizontal motion, so that it may follow the sun in its path. A vertical screw-rod attached to the back of the mirror draws the upper part slowly down, or again pushes it up, thereby altering the inclination of the mirror to suit that of the sun's rays. By the motion of these two screws the light from the mirror can be kept steadily fixed on any selected point. To make signals the above-named rod is pressed down against a spring, and after a short or long pause released, thus throwing the light on the station for the space of a dot or a dash." I may add that the description of "method of use" is accompanied in the manual by a figure, and complete instructions for working the apparatus. Any further information desired by "Magister Artibus" on the subject of signalling I shall have great pleasure in giving, as I have had considerable practice in the art.—A Volunteer Signaller.

[56632.]—**Stacks of Hay, &c.**—Oblong stack: Multiply length by breadth, and the product by height of body, and half height of roof added together, and the result will be given in cubic feet. In case of inequality in stack, averages must be taken. Oblong hipped stack: Only take ⅜ths of height of roof instead of entire height. Circular stack: Measure circumference half-way between ground and eaves; then multiply by perpendicular height of body added to ⅓th below point of stack. Should roof be flat, rather less than ⅓th.—Bream's Buildings.

[56636.]—**Australia.**—A good man will get plenty of work in Melbourne, probably wages from 8s. to 14s. a day; but there is not much room for inferior artisans. A man should take any special tools he may have; but ordinary ones can be bought at about London prices. Clothes and books are much the same as here, but books had better be taken. Several English companies are doing electric lighting work, so it might be possible to get a letter in England to a manager out there. This would be of the greatest use.—Rosicrucian.

[56637.]—**Electric Lighting by Batteries.**—A quart Daniell will give you one volt. Daniell cells are perfectly useless for lighting. Bunsen cells will last for about five hours, and then require to be recharged and the zincs reamalgamated. You had better not think of lighting anything above a small lamp, as the care and attention required in battery lighting is out of the question. If a "Young Beginner" wishes to make a few experiments in lighting, he had much better procure a small lamp of about five candle-power and light it up with a bichromate battery. The creeping salts in Daniell cells are always a source of trouble and annoyance. Several plans have been devised to obviate this, but without much success. As good a plan as any is to use very tall porous pots, and at the same time do not neglect to attend to them.—C. D. R.

[56638.]—**Cleaning Glass.**—The composition that seems to be required is made of five parts of spirits of wine and one part of ammonia, with enough Tripoli powder to make a thick cream.—Faber Fabrum Adjuvet.

[56638.]—**Cleaning Glass.**—So far as windows are concerned, if you put whiting on them, you give yourself quite unnecessary trouble, as unless they are very greasy indeed, a solution of soda applied with a sponge or wash leather will do all that is requisite in double-quick time. For polishing cloths use scrim canvas (paperhanger's canvas) which has been soaked and boiled until all the "dress" has been removed. See that your polishing cloths are clean, and then you need not have cloudy and dull-looking windows. To clean glass on which albumen is to be poured, or on which we wish to deposit a film of silver, is a very different matter; but after dusting we immerse the glass in a solution of nitric acid (10 to 1), and leave it there for some time. We then wash it under the tap, and while still wet pour the albumen on. In the case of silvering mirrors further precautions are taken. The photographer, however, who is very careful, polishes the plate after the nitric-acid bath with a cream of spirits of wine, tripoli, and ammonia liquor, while some use a mixture of bichromate of potash and sulphuric acid.—NUM. DOB.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

Since our last, W J. Grey has replied to 56282.

## USEFUL AND SCIENTIFIC NOTES.

**Galvanic Batteries.**—Mr. G. G. Blackwell, of Liverpool, has issued an illustrated catalogue and price-list of galvanic batteries, electric bells, &c., which is a great deal more than catalogues usually are, for it contains, within a small compass, a large quantity of valuable information, including a number of hints which will prevent beginners going wrong, although they may have strictly followed, as they believe, the directions which appear so simple in the books. Anyone who wants to make a battery should procure Mr. Blackwell's "Guide"—it deserves that title, although it is only called a price-list and illustrated catalogue.

**Prehistoric Structures in Micronesia.**—Capt. L. U. Herendeen, of San Francisco, communicates to *Science* the following notes on prehistoric structures in Micronesia:—"A few years ago I visited Ponapé Island, in the Pacific, in east longitude 158° 22′ and north latitude 6° 50′. The island is surrounded by a reef, with a broad ship-channel between it and the island. At places in the reefs there are natural breaks that served as entrances to the harbours. In these ship-channels there were a number of islands, many of which were surrounded by a wall of stone 5ft. or 6ft. high, and on these islands there stood a great many low houses, built of the same kind of stone as the walls about them. The walls are a foot or more below the water. When they were built, they were evidently above the water, and connected with the mainland. The natives on the island do not know when these works were built; they have even no tradition of the structures. Yet the works show signs of great skill, and certainly prove that whoever built them knew thoroughly how to transport and lift heavy blocks of stone. Up in the mountains of the island there is a quarry of the same kind of stone that was used in building the wall about the islands, and in that quarry to-day there are great blocks of stone that have been hewn out, ready for transportation."

THE following paragraph seems to have appeared too early in the season:—"Oranges coloured with fuchsine, so as to resemble the highly-prized 'blood orange' form the latest addition to adulterated edibles in Paris. Dyed tomatoes have also been offered for sale in Paris. The fruit not having acquired its usual deep hue, the producers covered it with red paint, for which on discovery they were fined 100 francs."

## QUERIES.

[56639.]—**Winnowing Machine.**—Would any of "ours" kindly give me instructions how to make a winnowing machine, such as is used for opening flocks, after being some time in use?—UPHOLSTERER.

[56640.]—**Detachable Stock for Revolver.**—I wish to fit a revolver I have with a detachable stock, for use as a small rifle. Can any reader give me a hint how to fasten the stock on, so that I can use it for both purposes without injuring the handle of revolver?—and oblige—W. D.

[56641.]—**Lease.**—A widow holding lease under will of late husband, desires to give it over to her two daughters during her lifetime. Is it necessary to have fresh lease drawn up, or by separate deed, or merely indorsed upon the existing lease, so as to be quite legal? Also, what would be the probable cost of the transaction? The value of the property would be about £300.—H. C.

[56642.]—**Petroleum.**—Will any of "ours" kindly inform me of any method or methods of detecting water in the presence of, and extracting it from, petroleum? After refilling, for a few weeks, the oil vessel of the lamp, I find that a quantity of water gradually accumulates at the bottom of the vessel, which water continues to increase until the light is entirely extinguished; the vessel has then to be emptied. How can this be obviated without emptying the oil vessel?—IN THE DARK.

[56643.]—**To Ostrich Feather Bleachers.**—If you would kindly give proportion of chemicals used and process for bleaching a small quantity of ostrich feathers, you would greatly oblige—JOHN THOMAS.

[56644.]—**Resistance Coils.**—To MR. BOTTONE.—I intend making a set of resistance coils as described by you in a recent issue. Could you please tell me what number G. S. wire to use, and also about what length of wire I should have to cut off for each number of ohms, so as to avoid cutting to waste?—AMATEUR.

[56645.]—**Small Gas-Engine.**—To "J. H."—Can you give us reliable information as to how to make patterns and fit up a small gas-engine, say ½-h.p.? I could constract one if I had reliable instructions how to do so, same as we are having on the steam-engine, but I am not in a position to purchase one at present.—THEO.

[56646.]—**Bicycle Painting, &c.**—Will someone kindly give me a few hints on mixing colours, especially lining colours? I mix with turps and varnish, but it seems to work stiff. Also how are the brass flanges secured to spindles?—C. B.

[56647.]—**Spring Jack.**—Will "Invicta," or some other kind reader of the "E.M.," inform "Spring Jack," how the strengths of springs vary (springs similar to a clock spring), also how to calculate for different strengths? Would the writer be correct in taking them as the squares of the thickness, and as the breadth, or how?—O.

[56648.]—**Bichromate Battery.**—I have two bichromate cells, which I wish to connect up and use together. One is a square pint, and the other a bottle bichromate, quart size. The former has of course the most carbon and zinc surface. If I connect up for quantity, does the difference in the size of the cell signify? If I connect up for intensity, supposing I have the latter cell on full power, how can I tell to what height to fill the former cells, so as to get them both the same power, and can you please tell me the meaning of the internal resistance of a cell? An answer to the above would greatly oblige.—AN AMATEUR.

[56649.]—**To "Sigma."**—Would Mr. Sprague favour a student of telegraph engineering with his opinion? The first case in point, is the effect of joining electro-magnets (in telegraph apparatus) in multiple arc, for purpose of getting rid of the retardation due to the extra current generated in them at the making and breaking of the circuit. I can understand that, in looking at the coils as generators of current, in the same way as you would at a battery, and remembering that the extra current generated varies directly as the convolutions for the same magnetising current, the effect of joining a pair of coils in multiple arc will be to reduce the extra current to one quarter what it would be if the coils were in series; but in Preece and Sievewright, (page 308) it is said that the extra currents in the two coils being in each case in the reverse direction, tend to neutralise each other, and little or no retardation from this cause is experienced. My difficulty is that whilst I can see they are reduced, I cannot see how they neutralise. The second difficulty is the method of arriving at the insulation resistance of telegraph wires, by the P.O. system of receive current testing. The tangent galvanometer is joined to the wire to be tested, and a current of known strength is sent from the other end, the wire under tests having at each end 10,000ω R. added to it, so as to make its own R., I suppose, comparatively insignificant. The strength of the received current is noted, and from a table provided, the equivalent insulation R. is known (Preece and Sievewright, page 266). I quite see that all the current lost *en route* must be through defective insulation, providing derived circuit to earth; but I cannot ascertain how the insulation R, equivalent to this loss of current, is arrived at. The Wheatstone bridge method, where the distant end is disconnected, is more readily understood.—TELEGRAPHIST.

[56650.]—**Lead Burning.**—I have made a bellows and 6in. lead-burning machine, exactly similar to the one described by Mr. Davies, Vol. XXXV. 909, 910, "E M." but sorry to say fail to get same to work satisfactorily, through the gas becoming exhausted so quickly, in fact say 5min. Can it be that my sulphuric acid is wrong, and if so, how am I to find out the quality required? Have added five of water to one of acid, as per instructions, but it fails to act on the bar zinc for any time. I also notice the flame rather a sluggish yellow cast, and easily blown out by bellows. I regret having to trouble Mr. Davies; but if he would kindly repeat his article from Vol. XXXV. No. 910, Fig. 231, September 1st, 1882, I should feel very grateful, as I understand the numbers are now out of print. Would he also give a few instructions upon upright burning, &c.? I have tried to do a little of it, but with very bad results. I should also like Mr. Davies to tell me if the exhausted acid, obtained when emptying the machine, may be used a second time, by adding more fresh acid, or is it better to use fresh water and acid each time?—A BEGINNER.

[56651.]—**Boiler.**—Will any brother reader kindly explain the cause of a serious accident which occurred on Monday last at the works where I am engaged? The boiler is a Lancashire one, 30ft. long, and 7ft. diameter, with two flues or tubes running through it. The fires were damped on Saturday and so left until Monday. Shortly after the damper was drawn on Monday morning, the stoker opened one of the fire-doors to ascertain how the fire was burning, when a most violent explosion occurred, shaking the whole place, and lifting the boiler from its seat. I shall be very thankful to know the cause of this, and to adopt any suggestion by which a repetition may be avoided.—ALBERT TURNER.

[56652.]—**American Organ Fix.**—Would be very thankful for practical information. I have a small one with one set of reeds of 4ft. diapason. I should like to add another 4ft. of same, and an octave of sub-bass; the bellows are smallish, and there is a little space on soundboard on top of them. I wish to know if I could place the reeds in an upright position, and connect the end of the reed tubes with the wind holes that have the pallets under in the soundboard. By this means I should gain a deal of room on soundboard; as it is, there is barely room to take two 4ft. sets, if laid flat as usual. If the reeds would sound well and do in this position, what would be about the least space of wind-hole I must have in soundboard, to supply each reed properly, as I want to economise all possible room, and find room for a vox humana?—AMERICAN O.

[56653.]—**Electric Bell.**—I am about to make an electric bell, with a gong 5in. in diameter, the poles of magnet to be ⅝in. in diameter, 2in. long, and 2in. apart from centre to centre. Will some of "ours" kindly advise me if this size is suitable, and also what quantity of wire I ought to wind the magnet with. Will No. 28 do, or is it too small? I intend using two cells Léclanche, and contact will be made by a clock close to the bell and battery, so that there will be comparatively no external resistance, other than the bell?—BEDFORDIAN.

[56654.]—**Portraiture.**—I have been trying to take portraits with one of Lancaster's ½-plate landscape lenses but cannot obtain any good results; so will some of my photographic friends give me a few hints, length of exposure, &c.? My failures are briefly this: In an ordinary well lighted room, with the stop in, and exposures up to ten seconds no image at all, up to 90 I get detail in dress, but the features come out dark in printing? How is this? Outdoors I do not succeed much better with the stop entirely removed giving 20 seconds exposure; but groups I get tolerably well, in from 8 to 10 seconds with the stop in. How do you account for this? Does a near object take longer to impress itself upon the plate than a more distant one? The plates I am using are the Uranium.—CAMERA.

[56655.]—**Cork Frames.**—I have taken to framing pictures with cork, but find it difficult on account of the cork being so hard and brittle. I beg to ask if any of your numerous readers could inform me if there is any way by which the cork could be softened and made more pliable?—MANXMAN.

[56656.]—**Planishing Tin-Plate.**—Will some practical plate-worker kindly inform me how to fasten a tin-plate that has been punched with small holes about ⅜in. apart? I find by hammering, that the plate becomes hollow in the middle, which I wish to remedy. Any information will oblige.—PLATE WORKER.

[56657.]—**Wirework.**—Will some kind reader inform me if over and under wirework is done by hand or machinery, and how is it managed to be done so regular? Is there any book on wireworking? Any hints would oblige.—PLATE WORKER.

[56658.]—**Boiler Enamel.**—Kindly let me know if there are any enamels or varnishes, for coating the inside of open boilers (cast iron) to prevent rust colouring materials used?—WM. FORSYTH.

[56659.]—**Cutting Ebonite.**—When turning up ebonite in the lathe for various electric apparatus, I find it almost impossible to keep any edge to the tools. Would some kind reader of the "E.M." kindly tell me if there is any special tool and method for overcoming this difficulty?—W. J.

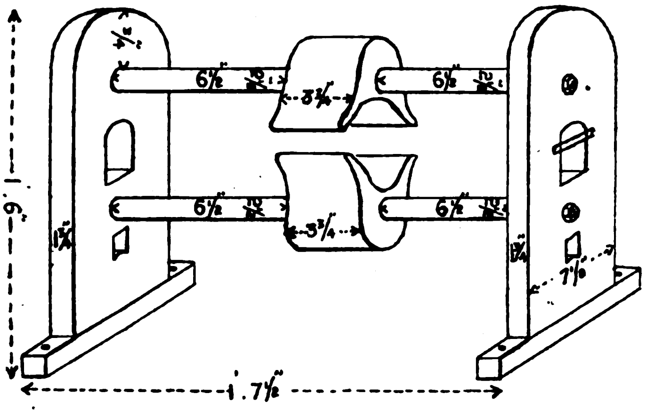
[56660.]—**Eclipses of Small Hand of 24h. Clock.**—In a 24h. dial, how can I find the time each hour at which the minute hand eclipses the hour hand, supposing the 24th hour, or zero, to be at the bottom of the dial?—C. H. T.

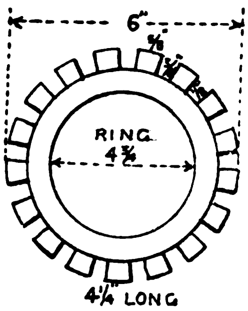
[56661.]—**Bending Iron Gas and Steam Tubing.**—I asked in some back number, how iron tube might be bent without reducing the size of the bore. I have tried the plan suggested, but cannot succeed with it. I have heard there is a method of bending while hot round a grooved pulley; but never having seen it done I should be glad of a description of the process.—C. H.

[56662.]—**The Nottingham Caves.**—In the town of Nottingham there are many large caves, caverns, or huge cellars, hewn out of the solid rock, it is said, by the ancients. Can any of "ours" inform me of the probable antiquity of these excavations, the purpose for which they were made, the tools used in the work, and what use our ancestors probably made of the loose stone chippings, &c., got out of these workings? As it is said none of this refuse has ever been found, and the quantity must have been immense.—C. H. T.

[56663.]—**Iron Planishing Machine.**—Will any correspondent give sketch and description of the planishing machines used for making rolled shafting? I suppose they are pairs of revolving discs peculiarly arranged, and I cannot, from a bare verbal description, understand their action on the iron bar.—KUNST MACHT GUNST.

[56664.]—**Dynamo.**—To MR. LANCASTER OR MR. BOTTONE.—I am constructing a dynamo on the Gramme four-pole type, but the armature has a Pacinotti ring, size of ring including cogs, 6¾in. diameter, and 4½in. long, and has 30 spaces for wiring, each space 4½in. long, ⅝in. deep, ⅜in. wide. I want to know how much double cotton-covered wire I shall want for the F.M., and also how much





and size for the armature, to be shunt wound? Could I run incandescent lamps and arc lamps at the same time if wound as above? Weight of machine when finished, 2cwt. How much light, incandescent and arc, may I expect if run by a half or one horse-power engine? A sketch showing how to commence wiring the F.M., and the direction to be wound in on each of the four poles, will oblige.—QUANTUM LIBET.

[56665.]—**Strad. Model Violin.**—Thanks to Mr. Leslie, but reply is not definite enough. Stradivarius, I am led to believe, made all his best violins a uniform thickness throughout. Would someone who knows, or who has had the opportunity of gauging one of those splendid instruments, please to let me know the exact sizes of such, as the ordinary model now made of Strad. is only an outside resemblance of the real thing, as mechanics can easily take a copy of that; but the inside measurement is what is hard to come at. One would require the use of a valuable old violin for that purpose.—J. TOWNS.

[56666.]—**Valve-Gear.**—I have an idea for a new valve-gear, which does away with the eccentric, and is worked by the piston itself, but at most it only admits steam during ½ of the stroke? Would it expand enough if at good pressure? and what is the usual cut-off on stationary engines for speed?—RIP.

[56667.]—**Drill-Chucks.**—I should be obliged if "J. K. P." or other practical contributor to the "E.M." could tell me which is the best kind of drill-chuck for holding power, durability, and truth of centring. I have been using a scroll-chuck for some time, but find that it has worn quite untrue, and never possessed much holding power.—W. E. F.

[56668.]—**Powerful Bichromate Battery.**—I want to fit up a bichromate battery to work a small motor intended to drive a model boat. As the carrying capacity of the boat is limited to about 20lb., perhaps some electrical contributor to the "E. M." would kindly advise. I find that four Fuller quart cells will drive the motor at great speed, but there is very little power to drive the propeller. The motor can readily be stopped by the slight pressure of a finger, although advertised to drive a sewing machine which would require far more power than to drive the boat. This form of battery appears unsuitable. How would six carbons and four zincs in one cell be likely to act? Would it be advantageous to have two cells of three carbons and two zincs each, rather than one as above? Is it also necessary there should be a certain volume of exciting fluid?—or (as weight is an object) could not the plates be arranged as closely together as possible, limiting the bulk and weight of solution? What object is there in surrounding a carbon and zinc with a great bulk of solution, apparently out of proportion to the size of the plates?—Q. S.

[56669.]—**Expansion of Metals.**—Could any of your readers inform me what would be the length of a rod of wrought iron when heated to 100deg. Fahr. if 36in. long at 32deg. Fahr., and if, when being heated, it would expand the same amount with each degree of heat? Also the same with regard to a rod of brass.—A.

[56670.]—**Groynes.**—Can any reader inform me of the best way to protect land which is being washed away by the sea? I am told there is a new system called "Dowson's Groynes." Can anyone give me particulars?—NO SIG.

[56671.]—**Porous Cells.**—I have a number of porous cells out of order, which I consider is due to the exhaustion of the peroxide of manganese. I have refilled them with a mixture of peroxide of manganese and carbon in coarse powder, but they do not work so good as when new. Will any kind reader tell me why, and assist me how to obtain the best possible results from them again?—DIFFICULTY.

[56672.]—**Tarpaulin.**—I have a tarpaulin, of which the dressing is worn off. How can I renew the surface so as to make it waterproof again.—CHROMIO.

[56673.]—**Mechanics.** — Can any correspondent furnish me with a full answer to the following question from Todhunter's Mechanics? I have succeeded in the first part, but cannot complete. "Parallel forces act at the angular points of a triangular pyramid, each force being proportional to the area of the opposite face: show that the centre of the parallel forces is either at the centre of the inscribed sphere, or at the centre of one of the described spheres."—J. O.

[56674.]—**Carbonado, Bort, Diamonds (Gems).**—Will Mr. Wenham, "S. E. S.", and all others interested in the use of the above as tools, give me all the information they can on the subject? 1. As to persons in England or abroad using them, or either of them, as tools for hard steel, or for stonework, or other purposes. 2. As to price of carbonado. I heard that Sir H. Bessemer was using the diamond for cutting lenses. Has anyone else heard of this, or did he use carbonado? Information of every kind will be appreciated.—A. P. BOWER, 35, Mecklenburgh-square.

[56675.]—**Lemon Juice.**—Will any kind reader tell me how I may preserve lemon juice so that I may keep it in bottle throughout the summer?—JULIA.

[56676.]—**Free Reeds.**—Will G. Fryer kindly say how I can make a tuning apparatus for harmonium reeds? Could I do this with a flutina bellows, as I want to make a cheap one? Could it be done by letting the bellows into a small table level with, or a little higher than, top, and have bellows closed by elastic cords at the ends, or by some other means, so that (having valve hole or holes at the bottom) I could work them with foot? I would like to have the top so that I could have several slide boards with slots on each side of them of different sizes, so that I could tune other reeds as well. What would be the best kind of wood, and thickness; and how many holes could I make do, and what size?—A POOR AMATEUR TUNER.

[56677.]—**Boring Small Wood Handles.**—Would any reader oblige with any information, or a sketch of an attachment to a lathe, for boring small wood handles, 4in. long, and what bits would be most suitable?—J. C. K.

[56678.]—**Hardening Jaws of Chuck.**—Will any of your readers tell me how to harden the jaws of a four-jawed chuck, 10in. in diameter, so that they will not warp in the process?—ALFRED WEST.

[56679.]—**Supported Beam.**—In the Honours Paper in Applied Mechanics set this year by the Science and Art Department, the following question is given: "A horizontal uniform bar, 18in. long, is laid over two supports, each 4in. from its ends. Find two points at which it has no tendency to break." Would some fellow reader kindly give the correct answer to it?—H. T. N.

[56680.]—**Induction Coils.—Vertical Plan.**—Will any of your readers tell me how they manage to see between the discs when they are about 1-20in. between, or do you let the wire run on anyhow?—L. W. WILLIS.

[56681.]—**Trueing Steel Square.**—I have a steel square, 6in. blade, which is not true. Will some reader kindly inform me of the best method to true the same,?—ONE ANXIOUS TO KNOW.

[56682.]—**Struck by Lightning.**—In December last I had the misfortune to be struck down by lightning, my feet, leg, and one arm being burned; but am thankful that all are well again; but there is an old scale left on the bottom of one of my feet. The bottoms of both feet are very tender, for when I get my shoes off I can hardly walk, as it gives me much pain. I am washing them two or three times a week in Tidman's sea salt and water, to harden them. When storms come on they are very painful; pains fly all over me (I believe some of the pains to be rheumatic); they seem to fly to the old wounds; my knee and right hip are very painful. Can ady of the readers of the "E.M." give me any advice to remove those pains and strengthen my feet?—A BRAND PLUCKED FROM THE BURNING.

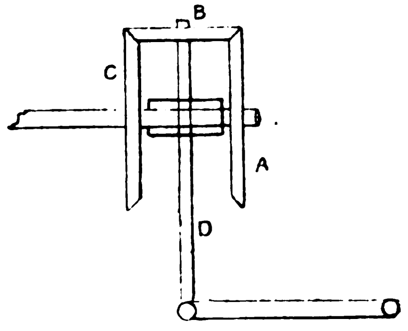
[56683.]—**Magneto Machine.**—To MR. LANCASTER, MR. WIESENDANGER, AND OTHERS.—I am about to try to construct one of the above, and to apply the electricity so produced in the form of an electro-magnetic engine, and am seeking information on the following points: 1. What amount of power could I hope to secure by employing ¼h.p. to revolve the armature? 2. What is the best form of magneto to employ? 3. Respecting the permanent magnets, any hints as to the quality of steel, best methods of magnetising would be gladly received? 4. Is there a better method than that of Planté's for storing up electric energy?—if not, hints as to the management of Planté's arrangement, also the amount of surface required for power absorbed; for instance, what is the least amount of surface that would be required to store the energy given off by six quart Bunsens in one hour?—PRESTONIAN.

[56684.]—**Electro-Motor.**—To MR. BOTTONE.—I have fitted up an H armature dynamo according to your instructions in these pages, with the exception of wiring. Would you kindly tell me the weight and gauge of wire to wind it with, so as to use it for a motor to drive a sewing machine. How many bichromate cells, with zincs 6 by 2, will it take to drive it?—I. K.

[56685.]—**Stiffening Woollen Cloth.** — Will some obliging fellow-reader tell me the very best material that can be used for stiffening thick woollen cloth? The addition of weight to the cloth is no object, a really hard feel only being required. I have been told it can be made as firm as a board. Farina and glue have both been tried, but the results are scarcely satisfactory.—ANGLETERRE.

[56686.]—**Bending Wood.**—I want to frame a thin square iron plate of about 30in. circumference with hardwood frame of birch, cedar, maple, or any other hard or medium hard wood. The frame to be ⅜in. wide and thick. When made with joints at each corner, it does not work well, and I am told that it is possible to bend the frame by some process, so that I shall have only one joint. Can any of your readers enlighten me as to the way of doing same, or refer me to some books on the subject?—FRAME.

[56687.] — **Wheel Calculations.** — Could any correspondent tell me how to speed wheels of this description? A being fast on the shaft, B loose on the handle, C fast on the shaft; A is stationary, D is the handle, wheels A and C are larger than B. Suppose A and C to be 50 teeth, B 28, what speed will C be? Example in plain figures will oblige.—SAMMY.

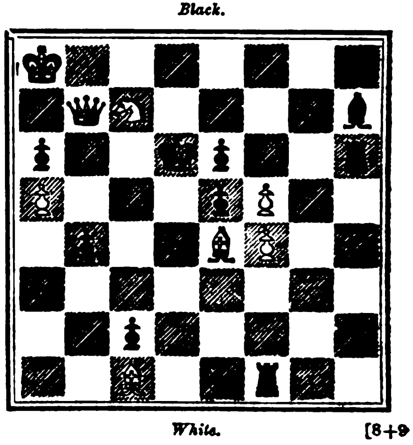


## CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

PROBLEM DCCCCXL.—DOUBLE PAWNS.

*Black.*



*White.* [8+9

White to play and mate in three moves.

SOLUTION TO 938.

| *White.* | *Black.* |
|---|---|
| 1. R-R 7 | 1. B takes R (a) |
| 2. Q takes B | 2. Anything |
| 3. Kt mates | |
| 2. Kt takes P (ch) &c. | (a) 1. Kt-B 2 (b) |
| 2. Q-K 5, &c. | (b) 1. K moves (c) |
| 2. Kt takes P (ch) &c. | (c) 1. Kt-B 3 |

NOTICES TO CORRESPONDENTS.

CORRECT solutions to 937 by I. H., S. L. Chivers, Exon (good), F. O'N. H. (a good study), H. Culmer; to 938, by F. O'N. H., Exon (pleasing, an unlikely key), I. H., A. W. Orr (spoilt by two move mates, otherwise good), A. A. B. Lecluse (there is a master-hand touch about this ingenious problem), B-B 2 nearly solves it), J. A. M. (wants a W P at Q R 4, to prevent dual moves of Kt in main play; poor, wanting in variety), G. T Stringfellow, Rev. W. Anderson (Old Romney), J. E. Piper, F. A. Vincent, H. Culmer, and A. S. Olver; to 939, by E. S., J. E. Piper (very pretty), F. A. Vincent, F. B. Webb, J. A. M., A. S. Olver, Streetgate, and R. A. Bennett.

R. A. BENNETT.—In your solution of 938, you have overlooked that when 1 $\frac{\quad}{\text{Kt-Q B 2}}$ 2 $\frac{\text{Kt takes P (ch)}}{\text{K moves}}$ if 4 Q-Q Kt 4, there is no mate on account of B P at Q-R 4.

E. STANLEY FOLLWELL.—See above notice.

BEGINNER.—2. Kt-Q 3. mate.

I. H.—If in 936 1 $\frac{\quad}{\text{R-R 6}}$ mate follows on the move.

A. S. OLVER.—It should have been four.

A LIVE albatross, the first ever brought to Europe, has just been received in the Paris Jardin d'Acclimatation.

## ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand*, *W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, May 20th, and unacknowledged elsewhere :—

Rev. C. J. Jones.—Rev. J. Rawlins.—J. B. Medland.—W. Astbury and Co.—Electric Apparatus Co.—Turner.—Alabama.—Trophy.—Capt. King.—Vulcan.—Vandu.—Vulcanite.—J. Townley.—A Convert from the Theory of Evolution.—Ignorant.—John Ballot.—St. Helens.—Edward Hines.—Cathode.—W. Sykes.—Verax.—Pure Food.—H. A. Wassell.—K. J. Tarrant.—Glatton.—Sammy.—M.I.C.E.

### CAUTION.

We regret to have to put our readers on their guard against a swindler who has recently been making use of our Sale Column. We particularly caution readers *not to send money before they get their goods* except by means of a Post-Office Order made payable ten days after date, and to stop the order and get their money back if the goods do not reach them before the ten days expire. We do our best to keep swindlers out of our advertisement columns, but they easily evade us by changing their names and addresses. Especially during the next few weeks we warn readers against "bargains." People who are ready to part with apparently valuable goods at ruinous prices should always be inquired about before money is sent them.

C. H. (If the wheels and the pinions on the two shafts are alike, as placed in your sketch the second shaft will revolve four times as fast. It is a simple matter of calculation. 2. It is almost invidious to answer such a question as "What is a good rudimentary work on astronomy?"; but possibly Sir E. Beckett's "Astronomy without Mathematics" (Society for Promoting Christian Knowledge) would suit you. Main's "Astronomy," published by Lockwood and Co., is a cheap and very useful treatise. 3. The chemical you mean is probably bisulphite of lime, but we were not aware it was used for "ageing" malt liquors. 4. The tendency to alter shape in surface plates is corrected in the Whitworth patterns. See the indices.)—C. H. Thompson. (What advantage is to be gained by combining "air, steam, and gases"?)—C. Henry. (Attempts have been made to start societies of the kind, and some of them have been successful in the provincial towns. They meet, however, at stated intervals. You should join one of the mechanics' institutes, or a workman's club. 2. It is done easily enough with surveying instruments, point by point.)—C. H. T. (Remains of the kind are found in various parts of the country. It is usually considered that the vicinity has been the site of some great battle, and the bones have been collected and put into the charnel-house. 2. It would strike against the side of the bore first, and finally rest in the centre. 3. The centre of the country could probably be found by that means as nearly as any other; but *cui bono*?)—J. H., Manchester. (We are not acquainted with anything of the kind. Even in the case of the larger automatic instruments, springs are always used.)—F. A. W. (For methods of preserving eggs see p. 469, Vol. XXXIII., pp. 503, 551, Vol. XXXVI. The commonest plan is to preserve them in a thin cream of lime, but many householders use solid paraffin or butter. The object is to close the pores of the shell from access by the air. At p. 551, Vol. XXXVI., you will find directions for keeping them by the thousand; but they may also be preserved in water dosed with either boro-glyceride or salicylic acid.)—W. C. (It is not clear from your query exactly what you want to do, but you will find full directions for all kinds of bronzing in comparatively recent numbers.)—Novice. (The query has been frequently answered. Coat with size or glue water first, and when dry, go over with gold size or varnish (copal). When that is tacky, dust on the bronze powder, and when all is dry and firm, brush off the superfluous bronze.)—A. J. Sells. (It is printer's or lithographic ink thinned, when it has to be driven through holes in a sheet of paper.)—Fuller's Earth. (Yes, it is used for oil-refining. We do not know where you could obtain crude petroleum.)—A Reader 2468. (The resistance of No. 15 B.W.G. copper wire is ·12679 ohm per lb., and 7·887lb. give one ohm resistance. Of No. 20, ·440lb. (nearly half a pound) gives one ohm resistance.)—G. B. (You must use paint ground up with varnish, or the ordinary ground colours, strained, and thinned with turpentine varnish or copal.)—Epping Forest. (We cannot accept the responsibility of advising. There is work and good pay for the right sort of people. Address the inquiry to the Crown Agents for the Colonies (Tasmania), Colonial Office-buildings, Downing-street, S.W., or to the Emigration Agents for the Colony, The Emigrant and Colonists' Aid Corporation, 25, Queen Anne's-gate, S.W.)—J. Hales. (See indices, or procure such a book as Watts's "Electro-Metallurgy," Lockwood and Co., Stationers' Hall-court, E.C.)—D. G. Jones. (See Electro-motors in the indices, and numerous replies under similar heads. You speak of an electric railway, when it is only a motor, and fail to state how much wire you have wound on the magnets and armatures.)—Safety. (Gasoline is one of the light constituents of petroleum, having a gravity of 87°. It is the third distillate, the fourth being naphtha, gravity 74°, and the fifth benzoline, with a gravity of 64°. Benzoline is really safer than gasoline, which is conveyed by the railway companies only under certain conditions, and can only be obtained, we believe, in large cans or barrels. We believe you will find an illustration of the identical furnace on p. 332, No. 925.)—Wm. Chisholm. (We do not remember it. You do not repeat the query; but as it is something about telephones we might suggest a perusal of the back volumes.)—E. Booth. (Most of the modern textbooks contain explanations of the principle of the telephone, and our back numbers have many notes and illustrations in connection with both receivers and transmitters. We do not know of any book giving instructions for keeping them in order.)—J. Prout. (Savart's violin was built up of two flat plates for both back and breast. These plates were made of two pieces ⅛in. thick on one edge and 1-12in. on the other. The thick edges were glued together. The length of body was 14in., width at neck 6in., at tail 8⅜, depth (outside) 2½in., bass bar in centre on joint of breast plate; soundpost near one of the straight holes. Materials: pine, and any suitable wood, but preferably maple for back.)—E. A. Williams. (Instances of the kind have been recorded; but it is generally believed that the "figures" are produced by congestion of the superficial veins.)—G. C. Fox. (Col. Ross's book is the best. It is published by Lockwood and Co., of Stationer's Hall-court, E.C.)—Nauticus. (Camphor carried about the person is perfectly useless as a disinfectant.)—Arnold T. Reed. (Several such scientific societies have already been successfully started under the auspices of the English Mechanic. For particulars, see indices of back vols.)—S. Stokes, G. Fryer. (In type.)

## USEFUL AND SCIENTIFIC NOTES.

**Composition Frame Ornaments.** — The following recipes for compositions of the above character may be found useful: Dissolve 1lb. of glue in 1 gal. water. In another kettle boil together 2lb. of resin, 1 gill of Venice turpentine, and 1 pint of linseed oil; mix all together in one kettle, and boil and stir until the water has evaporated. Turn the whole into a tub of finely-rolled whiting, and work it until it is of the consistency of dough. 2. Boil 7lb. of best glue in 7 half-pints of water. Melt 3lb. of white resin in 3 pints of raw linseed oil. When the above have been well boiled, put them into a large vessel and simmer them for half an hour, stirring the mixture and taking care that it does not boil over. The whole must then be turned into a box of whiting rolled and sifted, and mixed until it is of the consistency of dough. To use these compositions, proceed as follows: The proper moulds being prepared, they are thoroughly rubbed upon the inside with sweet oil, and the composition firmly pressed in. After removing the mould, the cast may be dried by a gentle heat, or while still plastic it can be applied in its proper place and bent into any position.

One thousand cubic feet of nitrogen weigh 80lb. at a temperature of 32° Fah. and a pressure of 15lb. per square inch; oxygen weighs 90lb.; the mixture of 770lb. of nitrogen and 230lb. of oxygen makes 1,000lb. of common dry air. As the oxygen is heavier, it occupies less bulk in proportion, so that if we take the air by bulk, 790 cubic feet of nitrogen and 216 of oxygen make 1,000 cubic feet of air, which will weigh 82lb. The amount of watery vapour is very variable, changes from hour to hour, and differs in localities; but the small amount of carbonic acid is less variable, and changes only from 1-2500th part to about double that amount.

In the absence of a duly authorised and official standard of filtration regulating the volume of water to be passed through a given area of sand in a given time, it has been found during the past twelve years that when the rate of filtration does not exceed 540 gallons per square yard of filter bed each 24 hours, the filtration is effectual; and this has been generally recognised as a tentative standard rate of filtration. The water companies all keep within this limit.

The experiments made at Vörösvar with the new five-barrel Nardenfelt mitrailleuse have, according to the *Times* Vienna correspondent, given the following results:—At 1,000 yards range 26 per cent. of the shots took effect on a target two mètres high. At 600 yards 70 per cent. of the shots struck. In the time firing 100 shots in twelve seconds and 480 in one minute were registered.

The *Miller* states that a large bakery on the Scotch steam bakery system is to be started in the south of London next autumn. There will be eleven ovens, besides an American reel oven, and the capacity will be at first 100,000 loaves a week, but provision will be made for increasing this fourfold if necessary.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., bound in cloth, 7s. each. Post free, 7s. 9d.
Vol. XL. now ready, price 7s. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words .. .. .. .. .. .. .. | 2 | 6 |
| Every additional eight words .. .. .. .. | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words .. .. .. .. .. .. | 0 | 3 |
| For every succeeding Eight Words .. .. .. | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words .. .. .. .. .. .. .. | 0 | 6 |
| For every succeeding Eight words .. .. .. | 0 | 6 |

⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists, London."—Also makers of Epps's Chocolate Essence

**Holloway's Pills.**—The stomach and its troubles cause more discomfort and bring more unhappiness than is commonly supposed. These Pills have long been the popular remedy for a weak stomach, for a disordered liver, or a very enfeebled digestion, which yield without difficulty to their regulating, purifying, and tonic qualities.—[ADVT.]

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—Caplatzi, Science Depot, Chenies-street, near British Museum. Established 1862.

54in. **British Challenge**, new last season, double ball bearings, and all accessories, lamp, &c. Inspection invited. Exchange for 6in. centre, 6ft. bed, back-geared, screw cutting Lathe, by good maker, and cash.—Bird, 16, Strawberry-hill, Pendleton, Manchester.

7 H.-P. Brotherhood Patent **Engine**, also nearly finished 50-light Dynamo. Exchange for Microscope, Tools, or offers.—A. J. Sells, 188, Mare-street, Hackney, E.

What offers in exchange for **Electric Engine** (locomotive), with four flanged wheels, forming a splendid model, about 7lb. weight; also new Cyclostyle, fcap. size, cost £3.—Thos. N. Andrews, Charles School, Plymouth.

**Printing Press, Type**, &c.; "British Battles," 2 vols. "Amateur Mechanics." quantity of "Cyclist," "Leisure Hour." Cash offers, or exchange anything useful.—BELCHER, Heybridge, Maldon.

3in. Vertical **Engine**. Exchange for brass LUBRICATORS and Oil Cups, new or second hand, value £3 10s. Offers.—J. L. GREENWOOD 14, Clarence-street, Cheetham, Manchester.

A very fine **Locomotive**, about three-parts finished; small Medical Coil, pair Telephones, very fine model vertical Engine, Phonograph. Offers. Stamp for particulars.—A. DAVIES, Brandon, Suffolk.

I want to exchange "**English Mechanic**," a week old, for "Carpenter and Builder," 1d. paper, 3 days old, regularly.—BULLARD, Newport Pagnell.

Six-keyed D **Piccolo**, cost 10s. 6d.; will take 5s. 6d., or exchange.—POOLE, St. James'-green, Thirsk, Yorkshire.

Exchange tubular copper **Boiler**, with water gauge and ¾in. cylinder, for a large good self-acting fountain or offers.—ROBERTS, 31, High-street, Mold.

One quart **Bottle Battery**, wants new zinc and carbons fastened. What offers?—Address above.

28 pure **Zinc Bars**, 7in. long, ⅜in. thick. What offers?—Address above.

Will exchange ¼ H.-P. Horizontal **Engine**, turned flywheel and governors. for good 54in. Bicycle.—M. LITTLE, 37, St. John's-road. Reading.

What offers for half horse-power **Steam Engine**, nearly new, brass cylinder, lagged in rosewood.—Apply, WILLSON, Coney-hill, Gloucester.

53in. **Bicycle**, worth £3 10s.; in exchange for a 2½in. or 3in. Telescope.—MELDON, 28, Newington Green-road, N.

**Perambulator Wheels**, new, ⅝ rubbers, turned axles, complete, plated caps. Exchange Silver Curb Albert. Mutual approval.—W. SMITH, Bilston-road, Wolverhampton.

Wanted, Lever **Watch**; good exchange. Wanted, offers for Youth's Tricycle, Meteor pattern; part finished 2-horse engine bed; 120 "E.M."—As above.

Warranted Crucible Cast **Steel**, 7-16in. to 1in. diameter, 1¼ to 3ft. lengths. Will exchange for anything useful.—H. GILBERT, Oxford-road, Sheffield.

Tough Mild Weldable **Steel**, 5-16in. to 1in. round, or square. Will take anything useful in exchange.—H. GILBERT, Oxford-road, Sheffield.

Wanted, good strong **Tricycle**, in exchange for superior Suit of Black Broadcloth, best quality, quite new, never worn, fit stout gentleman, about 5ft. 5in., cost £6 10s.—WM. HEFFER, Wokingham.

Beautiful exhibition 21 day marble and gilt **Clock**. height 28in., £25. Exchange for 5in. Screw-cutting Gap Lathe.—THOMAS, 160, Lancaster-road, Preston.

Hand **Sewing Machine**, complete, on white marble slab. What offers? Electrical apparatus, engine or lathe castings, or chucks.—R. SINCLAIR, 11, Sandyfaulds-street, Glasgow.

What offers for two polished mahogany **T Squares**, new, one 6ft. and one 5ft.; blade 3¼in., chamfered both edges.—ALEX. MILLER, New Prestwick, Ayrshire.

**Fishing Rods.**—Good Trout, Roach Rod, and Ebonite Reel; Hair. Silk Line. Exchange light Wood Turner's Lathe, treadle.—5, Frederick-street, Saviour's-road, Leicester.

Large **Telescope**, by Donald, on tripod stand, with circular motion. Will exchange for 50in. Bicycle.—C. F., 19, Merrow-street, Walworth-road, S.E.

Faulkner's (artificial) **Diamond Ring**, cost a guinea, good as new. What offers? Cash or any exchange.—W. S., St. Peter's Cottage, Forest-rise, Walthamstow.

**Oil Portrait** of Disraeli, supposed valuable. Offers wanted; cash or good exchange. Can be seen.—S., Third Floor, Wardrobe Chambers, Doctors'-commons, E.C.

**Drilling Frame**, adjustable arm, stock, drills, cramp, screw-plate, vice, grindstone, in box. Exchange for Locomotive or Horizontal Castings, half horse-power, or offer.—A., 17, Peach-street, Queen Park Estate, Harrow-road, W.

Wanted, a good practical work on **Electrical** MEASUREMENTS. Exchange.—Apply, A. REED, Longfleet, Poole.

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—KING, MENDHAM, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—KING, MENDHAM, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—KING, MENDHAM, and Co., Bristol.

**Wimshurst Influence Machine.**—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—KING, MENDHAM, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free.—As above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Plating.**—Every description of Gilding, Silver Plating, Oxidising, and Bronzing, executed with very best finish. Speciality in nickel-plating. Special quotations on application. Send one stamp for price list. Small jobs attended to per return post.—MORRIS COHEN, 132, Kirkgate, Leeds.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—HEWITT, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—MILLAR, Proprietor.

**Billiards.**—Great success of Thorpe's Patent Automatic Cue Tips. Cannot fly off. Cues retipped instantly.

**Billiards.**—Excellent testimonials from Roberts, jun. champion, and other professionals. £5 per week easily earned.

**Billiards.**—District Agents wanted. Send 9 stamps for particulars and sample cue end fitted with patent.

**Billiards.**—Five Shillings for sample cue, also fitted, and 3 extra tips. Thousands already in use.

**Billiards.**—Apply to sole representative for United Kingdom.—A. W. MORGAN, Lancaster Avenue, Fennel-street, Manchester.

Hard **Vulcanised Fibre** for Magnet Heads.—MOSSES and MITCHELL, 68a, Chiswell-street, London, E.C.

Hard **Vulcanised Fibre** for all kinds of insulation.—MOSSES and MITCHELL, 68a, Chiswell-street, London, E.C.

**International Inventions Exhibition**, East Avenue, Group 21, Stand 1683.—MOSSES and MITCHELL, 68a, Chiswell-street, London, E.C.

Tudsbury and Sons' "High Tension" **Wimshurst** MACHINES, with Compound Ebonite Plates. List, one stamp.—Edwinstowe, Newark.

24 **Microscopic Slides**, in box, very cheap. List sent for stamp.—WALL, Dalmain-road, Forest Hill.

**Tricycle Wheels**, Bicycle Wheels, and Fittings Wonderfully cheap. Also for safety Bicycles.—W. GWINNETT and Co., Wolverhampton.

**Lathes**, Lathes. Cheapest and best. List, 2 stamps Nothing equal at price.—ROBINSON, Somerset-road, Sheffield.

100 **Foreign Stamps**, including Brunswick, Ceylon Tasmania, Egypt, Greece, Luxemburg, free 7d.—HELY, Foley street, London.

**Tricycle House**, full size, portable, held two bicycles, £5 10s., carriage paid.—X., 7, Clarence-street, Liverpool.

A few Gramme **Dynamos** for sale, cheap.—WALKER and OLLIVER, 195, Severn-road, Cardiff.

**Electro-Motors** from 25s. No dead point. Battery equal Bunsen's. No fumes.—WALKER and OLLIVER.

Leclanché **Cells**, Manganese, Sal-ammoniac, Bichromate Bells, Wire, Pushes. Wholesale and retail.—WALKER and OLLIVER.

**Dynamos** repaired or rewound. Advice given. Competent men sent to all parts.—WALKER and OLLIVER.

Send for **List** of Switches, Indicators, Telegraph Instruments, Parts, &c., for sale, cheap.—WALKER and OLLIVER.

**Lamps**, 42 and 59 volt, Swan, £3 15s.—H. HEWITT, 21 Westbourne Park-crescent, Paddington, W.

**Leclanche Batteries.**—No. 1, 15s. 6d.; 2, 18s. 6d.; 3, 22s. Cash.—Address as above.

**Copying Ink Pencil**, new patent indelible, Cam action; best ever introduced. Warranted to wear well. Post free 7 stamps.—PURKESS, 37, Huntingdon-street, Kingsland.

**Piles cured at once** by using Dr. Farquharson's Remedy. Free by post for 2s.—2, Standish-street, Burnley.

**The Kinetic Engineering Company**, 36 and 37, Brooke-street, Holborn, London. Circulars and list post free

**Dynamo Wire**, 1s. 2d. per lb. Line Wire, 29s. 6d. per mile. Pushes, 4s. per dozen.—KINETIC COMPANY.

**Leclanche Cells**, best. No. 1, 16s.; No. 2, 19s.; No. 3, 22s. 6d. per dozen.—KINETIC COMPANY.

**Electric Bells.**—Best quality, workmanship, appearance and value in market, 40s. per dozen.—KINETIC ENGINEERING COMPANY.

**Maiche Patent Battery.**—Best yet produced. Circulars and Scientific Reports post free.—KINETIC ENGINEERING COMPANY.

**Electrical Supplies.** Wholesale only.—KINETIC ENGINEERING COMPANY, 36 and 37, Brooke-street, Holborn. London, E.C.

**Devonshire Cream**, delicious, by improved centrifugal process. Parcels Post, lb., 1s. 6d.—G. BULL, Manor Farm, Martock, Somerset

**Microscopes** (Binocular and other). All kinds of Apparatus. Double, Triple. and Quadruple Nosepieces to the trade. Stamp for list.—R. G. MASON, from J. Swift, 24, Park-road, Clapham, London, S.W.

Model **Boilers** of copper. Low prices. All sorts. Send requirements for price.—MONTGOMERY, Stanners-street, Greenock.

For sale, cheap, a quantity of **Organ Materials**, new and second-hand.—R. T., 164, Kennington-road, London.

Scottish Scenery **Photographs**, 7in. by 4in., extraordinary value, 4d. each.—Address, PHOTO, 182, Trongate, Glasgow

Gravet's **Slide Rule**, recommended by H.M. Government officials. Write for prices and testimonials.—Sole Agent, FARRAR, Benson's-buildings, Leeds.

**Microscopic.**—Well mounted Slides, 6d. each; 5s. doz. List and sample, 7 stamps.—TURNELL, Victoria Pharmacy, Southsea.

**Chemical Apparatus.** — Catalogue, 90pp., 500 illustrations, posted 2d.—W. HUME, Lothian-street, Edinburgh.

**Photographic Apparatus and Chemicals** for professionals and amateurs. See new illustrated catalogue, post free.—HUME, Lothian-street, Edinburgh.

Brazilian Pebble **Spectacle Glasses**, rough slabs or polished.—RICHARD BAKER and Co., 9, Mincing-lane, London.

Brazilian **Pebbles and Crystals.**—RICHARD BAKER and Co., 9, Mincing-lane, London.

**Mica**, otherwise Talc.—RICHARD BAKER & Co., 9, Mincing-lane, London.

**Thought-Reading**, Mesmerism, Ventriloquism, and Clairvoyance, complete instructions, 3d. each. All four, 14d. post free. Success certain. Never fails.—G. MARQUIS, Allhallowgate, Ripon.

**Inventors and Amateurs Assisted** in making Instruments, Models, and Patterns, &c., &c.—E. CHICK.

**Scientific and Electrical Instruments** made for the trade.—E. CHICK, 24, Woodbridge-street, E.C.

**Planing**, not exceeding 10in. by 10in. by 8in.—B. W. CLEGG, 18, Belinda-street, Hunslet, Leeds.

For **Model Work** (wheel-cutting in brass only); also Boring, Turning, and Screw-Cutting.—CLEGG, as above.

A New Varnish.—A **Spirit Copal**, as clear as water; never produced before; dries in five minutes; brilliant. Samples, post free, 7 or 14 stamps.—S., 5, Coventry-street, W., London.

**Dynamo**, powerful and useful, for sale; 150 c.-p. series wound machine, fitted with Siemens patent armature, either for hand or steam power, on polished mahogany stand, quite perfect, satisfactory reason given for parting, £6 10s.—CHAS. GORRINGE, 587, Holloway-road, N.

Handsome **Aviary**, height 6ft. 6in. by 3ft. by 2ft., bow front, on own legs, £3. Pair of Australian Parrakeets, 15s.—D. MCCARTHY, 879, Old Kent-road.

**Improvements in Filaments**, a speciality for incandescent lamps. Capital required. Open to offers to manufacture.—CARBON, 43, Chatham-street, Battersea Park-road.

Nearly new Thirlmere **Water Motor**, cost £9; sell for £3 3s.—HUBER, Fire Station, Bolton.

Sale.—Half-plate **Tourist's Camera**, good make, 3 double dark slides, and tripod stand, cheap.—Mr. WILLIAM ROGERS, 11, Cook-street, Liverpool.

The **New Saw**, to work by hand or foot, which so many cannot believe, will cut 3ft. 8in. of inch wood after you take foot off treadle. Will be shown at Stand 437, Inventions.—BRITANNIA Co., Patentees.

**Sliding Mandrel Lathes** for cutting screws in wood or metal. We are about making a 5ft., 5in. centre, price £16. If orders for twelve lathes lower prices can be taken.—BRITANNIA COMPANY, 99, Fenchurch-street, London. All letters to Colchester.

**To Ornamental Turners.**—We offer Ornamental Drill Spindle 30s. Drills, 1s. each.—BRITANNIA Co, Colchester.

**Eccentric Cutter Frame**, £2 10s. Cutters, 1s. each. Ornamental Tool Cutter, 15s. Tools for same, 1s. 6d. each.

**Easy Terms of Payment** to those who can give first-class reference.—BRITANNIA Co,

Second-hand **Lathes and Slide-Rests.** Send one stamp for list; six stamps for list of lathes and parts, rough and finished.—BRITANNIA Co.

**Notice!**—BRITANNIA Co. exhibit in Section 4, Stand 437, Middle Court. See plan. As you enter proceed to extreme end of Middle Court.

**Inventions Exhibition.**—We exhibit small Hot-air Motors, suitable for punkahs, fret-saws, pumps, saws, and sewing machines, price £9. Cost per day 1½d. Larger size, suitable for small lathe, £27 10s.—BRITANNIA COMPANY, Colchester.

**French Polishing**, Staining, Painting, and Varnishing. 122 Recipes or Trade Secrets. with full instructions and details, post free, 1s.—I. TOMLIN, 28, Highfield-terrace, Barnsley, Yorkshire.

**Castings.**—Half horse-power Horizontal, Vertical, or Launch Engine Castings, complete, with brass work and forgings, 12s 6d. One horse-power, 25s.—TOMLIN, Highfield-terrace, Barnsley, Yorkshire.

**Castings.**—Bench Drilling Machine Castings, complete, 3s. 6d.—I. TOMLIN, Highfield-terrace, Barnsley, Yorkshire.

**Castings.**—All Brass Engine Castings, horizontal or vertical, suitable for model work, 2s. 6d. set.

**New Designs and Price List** of Perfected Engines and Castings, post free.—I. TOMLIN, Engineer, 28, Highfield-terrace, Barnsley, Yorkshire.

Universal **Cutter Frame**, slides 3in., price £2. Castings, 4s. 6d.—Particulars, address, WM. ALLSOP, Derby-road, Belper.

**Patents, Designs, Trade Marks.**—JAMES STEVENSON, The People's Patent Agent, 26, Paternoster-square, E.C.

**Blue-black Ink**, Non-corrosive Ink, Fruit Salt, Hop Bitters, Abyssinian, Assyrian, Oroide Golds. Testimonials below.—STANLEY.

**Testimonial** (extract):—"Tried fruit salt formulæ . . . . all right . . . . shall save 2s. on every 2s. 9d. bottle."

**Revised Terms.**—Recipes (5,000), 6d. each; three upwards, 4d. each (postage extra).—STANLEY, 119, Manchester-road, Poplar.

**Bottles for Chemists**, Wine and Beer Merchants, sample tubes, cases, and boxes.—EDWARD W. DAUBY, Hull.

**Incandescent Lamp** in Scarf Pin, 20 stamps.—NEW and Co., 24, Dean-street, Soho, London.

**Incandescent Lamp**, 8d. post free. Only a few left.—NEW and Co., 24, Dean-street, Soho.

**Incandescent Lamp**, Battery, Wire, Chemicals, Instructions, &c., in box, 2s. 6d. free.—NEW and Co., 24, Dean-street, Soho.

**Assistance Given** upon moderate terms by experienced practical engineer and draughtsman.—630, Commercial-road, E.

**Optical Glass** of finest quality, crown and flint; all sizes in stock to 14 inches diameter, discs and sheet.—BUCKINGHAM, Blenheim-grove, Peckham.

Cotton-covered **Wire**, D.C. 10 to 18, 1s. 9d.; 20, 22, 24, 26, at 2s., 2s. 3d., 2s. 6d., and 3s. per lb.—C. DARVILL, 6, Brent View-road, The Hyde, London, N.W.

**Organ** (small chamber); must be sold, entire or in parts.—W. LEDSHAM, Grocer, Whitchurch, Salop.

Celebrated Kerry **Ferns.** 12 varieties, including Tunbridge filmy, 1s. 5d. free.—FITZPERY, Rathanny, Tralee, Kerry.

**Cyanotype Paper**, 4d. per sheet. Specimen and list free.—HUMPHRIES, Photographer, 44, Cornwallis-road, Holloway, London.

Good **Violin**, with bow, case, complete; also Music Book, cash 25s.—Rev. BURLON, Jarrow-on-Tyne.

"**Man, Know Thyself.**"—Obtain the only correct way of reading your character. Full instruction with chart, 7d.—H. DYKE, 46, James-street, Taunton.

**Reflector Telescope**, 6¼in. Calver, with several eyepieces, to be sold owing to illness of owner.—Address, G., 4, Philbeach-gardens, S.W.

**Odd Spiral Springs** made to order. Mattress Spring, 9d. per dozen.—JAMES PARISH, 52, Bard-street Park Sheffield.

**Pamphlet**, "Polarised Light as Applied to the Microscope." simple explanation. Three stamps.—E. HOLMES, 149 Essex-road.

Fine 3¼ **Astro. Telescope**, by Wray, £13; excellent definition. Tests given.—T. CLAPHAM, Austwick Hall, Lancashire.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. JONES.

**Dynamo Castings**, Jones's patent H: 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s.; 70, 16s. a set.—H. JONES.

**Dynamos**, finished: 8 c.-p., 30s.; 16, 36s.; 20, 40s.; 30, 50s.; 70, 100s. each.—H. JONES.

**Dynamos** for house lighting.—Jones's Patent Laminated Fields and Armatures, 5, 6, and 7 lights, £6, £7, and £9 each.—H. JONES.

**Dynamo Machines Repaired.** Motors, with wire, 5s. 6d.—H. JONES, 48, High-street, Lambeth, S.E.

**Coca Leaves.**—You require nothing but these at Whitsuntide. No necessity to carry heavy luncheon bags.—MARKS and Co., 17, Newcastle-street, Farringdon-street, E.C.

**Coca Leaves.**—The Bolivian Consul-General has sent a splendid testimonial this week in favour of their stimulating properties.

**Coca or Cuca Leaves.**—Many M.P.'s and Clergymen take them constantly. To Cyclists they are a positive necessity.

Persons afflicted with **Indigestion** should chew Coca instead of eating a hearty dinner, and they would soon be cured.

**Coca Leaves.** — Sample packet, with medical and scientific opinions, 13 stamps.—MARKS and Co., 17, Newcastle-street, Farringdon-street, E.C.

AND WORLD OF SCIENCE AND ART.
FRIDAY, MAY 29, 1885.

## TOOLS AND CUTTER BARS.

RECURRING to the contents of the last paper on this subject, it will be evident that the relief angle, or, as it is commonly called, the *clearance*, is not even in "end on" tools needed in front only or chiefly, but on the two lower faces of the tool, which are respectively opposite to the shoulder and the cylindrical portion of the work; that is, in a cranked tool, A, Fig. 16, the clearance is needed on *a*, *b*, the lower faces, and not on the front line, *c c*; but in grinding the former, the latter will share the effect.

It is, however, as "D. H. G." used to point out, an accidental line formed by the meeting of the two front faces of a tool. It, nevertheless, comes into importance when the top face is ground to give the required degree of sharpness to the cutting edges, as the angle of these edges is dependent upon it. The angle contained between *a* and *b* in the sectional drawing (B) of this tool determines the angles of the two cutting edges. The proper way to grind such a tool is, therefore, to form first the two lower faces, so as to give the required clearance to both, and then, having thus obtained this front or guide-line, to grind off the top face at a given angle to it, forming at once the two cutting edges. After this has been done, the extreme point may be rounded, and the result will be the production of the best round-end tool that can be made upon a grindstone.

There is, however, one method not likely to be adopted, perhaps, but theoretically correct, by which an ordinary round-ended tool, ground to a proper clearance angle, can have an edge made equally acute all round the curve—viz., by grinding its upper face as a hollow cone (Fig. 17, A) by means of a conical grinder like an obtuse-angled countersink. This would form an excellent tool; but all beyond the line *a b* should be removed to facilitate the escape of the shavings. The tool will then appear like B of this Fig. We may now desert for a time the solid tools, and consider the cutters, made of short bits of steel held in some sort of bar, which is to be considered merely as the handle. "D. H. G.'s" first lesson, indeed, was always to this effect—that nothing need be considered but the actual cutting edges, and that all the rest of the tool was merely a holder or handle by which these edges were supported and placed in position. Hence, it was allowable, and often advisable, to file away all the parts adjacent to the edge that were likely to be in the way; to ignore shape and beauty of form, and the symmetry of the two sides or edges, and to sacrifice everything to the parts intended to be brought into action; to form these correctly for the special work required of them, and then to bend, or file, or twist, or do as you please with the rest of the tool,

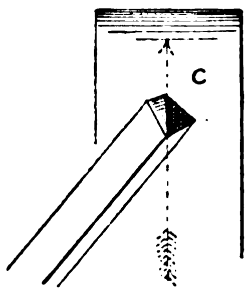

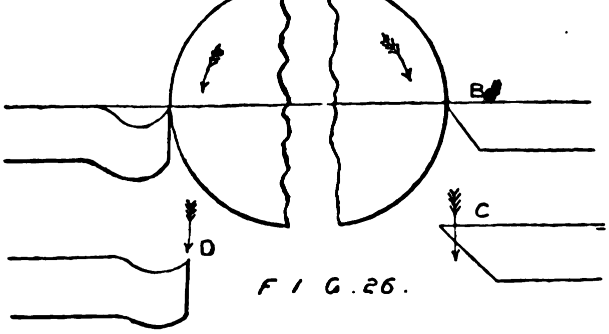

FIG. 26.

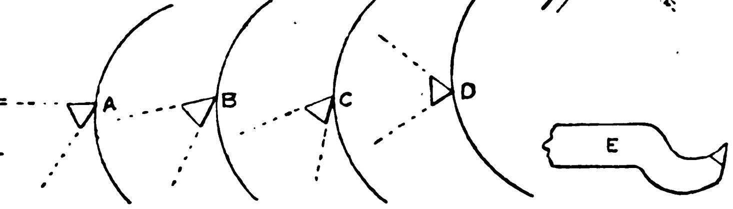
FIG. 27.



so as to make it serviceable for its purpose as a holder of the actual cutter.

Haydon's normal cutter (Fig. 18, A B C) has a front or plan angle of 120°. The upper face makes with the front line (formed by the meeting of the lower faces) an angle of 55°, giving cutting edges of 60°, forming a tool for turning up a cylinder or shaft of wrought iron.. The extreme point was generally slightly rounded upon an oil-stone. It had a clearance of 3°. The following edge was placed nearly parallel to the work, except sometimes in taking a rough cut, when the tool was worked to and fro, cutting in both directions. This was never the case in finishing cuts, nor generally in early stages of the work. To insure equal edges the line A B, Fig. 19, must be perpendicular to C D. If the upper face is inclined as E F, the right-hand edge will be sharpest, and *vice versâ*. The line B C bisecting the point must always for this reason lie in the run of the grindstone. The importance of this apparently self-evident fact is often overlooked, and should, therefore, be thoroughly understood. Suppose, e.g., the tool formed with one edge further round to the left (Fig. 20, A), only, of course, the face will be turned down on the stone, the natural way would be to lay it with the shank parallel to the run of the stone, as shown; but the edges *a b* would not be equally sharp. The arrow bisecting the point is the proper grinding line, and this, and not the shank, must be in the run of the stone. The tool must consequently be as at B—face downwards (as in practice it would lie upon the stone) it would appear as C. Although in practice it will not be necessary always to start with the normal tool, and then by filing and grinding to model it according to necessity, yet it is as well to this at first, in order to keep the principle fairly before the mind. A set of wooden cutters as models will teach the lesson as well as metal ones, as it will soon be found that out of the normal tool many others can be formed suitable for special circumstances or difficult and awkward jobs. Taking the normal tool represented at Fig. 18, A and B, it is evident that there is no positive necessity to have the point central. We can make it at *a* (Fig. 21, A), and the grinding line will be *b*, *c*, bisecting the point as explained. We may then file it out on one side till we get such a side tool as Fig. 21 B, whose parentage few but the initiated would discover. But it is plain that its angles will be as correct as those of the normal tool which originated it, as the actual edges remain unaltered. Again, as the normal tool must lie on the table of the rest at an angle, and not perpendicular to the axis of the work, in order to place the following edge parallel to it, "D. H. G." was accustomed to get the leading edge round somewhat to one side, so as to bring the following edge parallel while the tool lay in its more usual position at right angles to the work, thus, in reality, making it somewhat of a left-hand tool, if intended to travel in that direction only. This is a mere question of convenience. The tool shank *need* not lie perpendicularly to the line of centres, unless in taking a slanting position it is in the way at all; but I speak of it to show how entirely independent of circumstances the workman is, and how readily he can, without the use of forge, shape his cutters to suit his work. Of course, an angle of 120° is useless for rectangular corners; but so satisfactory is this normal tool in other respects that "D. H. G." advised its use always as far as admissible, only changing it for one of smaller angle when the corner would no longer admit it. Once again taking the normal tool as the foundation, the round-end tool is made in this way to render it as nearly as possible theoretically correct—*i.e.*, with equal edges. The "end on" round tools result from simply rounding slightly the apex of the tool of 120°. The edges first formed are already equal, and only the apex is affected, and that not materially. A right and left pair of similar round tools are the result of grinding the first or leading edge considerably to one side, then grinding the second at a large angle, and rounding off the point, filing away all that is not needed. Fig. 22. A B are two views of a side tool from "D. H. G.'s" drawings, and here again *a b* gives the grinding line bisecting the point, the cutting edges being *a c* and *a d*.

Departure from the normal 120° sliding and surfacing tool is, of course, necessary in very many instances, there being no hard and fast line or rule without exception in this matter. Here, for instance, also copied from a sheet by "D. H. G.," kindly lent me for the purpose of this paper by "J. K. P.," is a screw tool, the angle of which is 55°. Fig. 23, A, is the top or front, B the under side or back, showing the two lower faces. Then again, from the same source, in Fig. 24 are two views of an 80° tool for brass. These ground at a still larger angle may be made to scrape instead of cutting. The method of grinding these cutters I must postpone until I have given an account of the bar or holder for which they are designed, as they are ground when clamped in it. This will form the subject of the next paper. Fig. 25 is added to illustrate the result of tilting the shank of a tool in order to give more clearance or to lower slightly the edge—a practice exceedingly common and highly to be reprehended. The consequence of this alteration in position is to convert the tool more or less into a scraper, as shown by the dotted lines. This will be the same if the tool is like Fig. 16, and if the edge is at all thin, the tendency to break it will also exist, as the strain will come directly across it in its weakest part. Very probably some of my readers will say that too much is made of these theoretical tendencies, and that in actual practice it answers very well to tilt a tool. The writer has often done it when lazy, *and it does not answer, and it never will*. Given power enough, a tool may be made to tear off chips when it is badly ground and badly placed; but it will not cut clean and make the best work, which is what we are now endeavouring to teach. Fig. 26 is intended to show how the tool is weakened by excessive clearance, yet I have myself bought sets of slide-rest tools ground ready for use with even more clearance than is represented at B. The arrow at C shows the direction of the strain, and the point being unsupported could not possibly stand long. D shows a small clearance angle, and it will be seen that there is ample metal below to support the edge, and the smaller the clearance the greater will this support be. This is to be remembered quite as much with respect to cutters to be used with cutter-bars, as with solid tools, the principle of cutting-edges being the same in all cases; but here, again, comes into effect the position of the tool in regard to height of centres. If it is placed to cut exactly at the height of centres, the tool can have the smallest clearance angle and the keenest edge, because this will have efficient support, and may consequently be keener. Again, the direction of cut in wood or metal should be as nearly tangential as possible, which it cannot be with a fixed tool in the slide-rest, unless the clearance angle is small. A very convincing experiment—at least it was so to me—may be made by grinding a 3-square file so as to remove the teeth. This will give a tool with cutting edges of exactly 60°. Place it across the Tee of a hand-rest in two or three positions, A B C D, Fig. 27, applying it at the end of a bar or on the edge of a disc. The position A will give too much clearance, and the upper face will be also too horizontal, and the tool will merely scrape as it will at D, where these conditions are still more exaggerated. Placed as B, with diminished clearance angle, the upper face will now cut, and if the clearance is still further diminished, as at C, the upper face is more nearly tangential, and the cutting power will be at its best. This experiment shows how mutually dependent are the clearance and the position of the upper face. And if we were now to transfer the little equilateral triangle to form the tip of a cranked tool E we get exactly the same conditions. Now when the tool is a double-edged cutter the same rules apply; but instead of the point it is each face which has to be dealt with in this matter of clearance and cutting edge. The two lower faces are those on which the clearance has to be obtained, the upper face common to both of these stands in the same relation as that of the upper face of the 3-square file. It is true that in turning a cylindrical bar one edge attacks the cylinder and the other the flat face of the shoulder; but observe that we first tried the 3-square tool on a flat face, and then on a cylinder, and in each case we have found the same conditions necessary, and to exactly the same degree.

O. J. L.

(*To be continued.*)

## ASTRONOMICAL NOTES FOR JUNE, 1885.

### The Sun.

| Day of Month. | Souths. | At Greenwich Mean Noon. | | |
|---|---|---|---|---|
| | | Right Ascension. | Declination North. | Sidereal Time. |
| | h. m. s. a.m. | h. m. s. | ° ′ ″ | h. m. s. |
| 1 | 11 57 34·52 ,, | 4 38 7 | 22 7 2 | 4 40 32·00 |
| 6 | 11 58 24·45 ,, | 4 58 39 | 22 42 9 | 5 0 14·78 |
| 11 | 11 59 22·42 ,, | 5 19 20 | 23 7 20 | 5 19 57·57 |

| 26 | 0 2 34·16 ,, | 6 21 40 | 23 21 29 | 6 19 5·92 |

The method of finding the Sidereal Time at Mean Noon at any other Station will be found on p. 355 of Vol. XL.

At 7 a.m. on June 21st the Sun is said (technically) to enter Cancer, and Summer is supposed to commence. At this instant he will really be a little to the north-west of η Geminorum. This is the longest day, the Sun being above the horizon for 16h. 33m., and, of course, only 7h. 27m. below it. There is no real night in the British Islands during the entire month. Spots and faculæ, in somewhat diminished numbers, continue to appear on the Sun's disc.

### The Moon

Enters her Last Quarter at 4·8m. after midnight on the 5th, and is New at 10h. 42·1m. p.m. on the 12th. Tolerably high tides may be looked for about the 13th. She will enter her First Quarter at 1h. 48·5m. in the afternoon of the 19th, and be Full 42·1m. before noon on the 27th.

| Day of Month. | Moon's Age at Noon. | Souths. |
|---|---|---|
| | Days. | h. m. |
| 1 | 17·9 | 2 30·1 a.m. |
| 6 | 22·9 | 6 17·1 ,, |
| 11 | 27·9 | 10 32·7 ,, |
| 16 | 3·6 | 3 36·2 p.m. |
| 21 | 8·6 | 7 44·2 ,, |
| 26 | 13·6 | 11 39·5 ,, |

The Moon is in conjunction with Mars at 1 a.m. on the 11th; with Mercury at 4 o'clock the same afternoon; with Saturn at 6 a.m. on the 13th; and later on with Venus at 5 p.m.; lastly, she will be in conjunction with Jupiter at 3 p.m. on the 17th.

### Occultations of Fixed Stars by the Moon.

Ec Eclipse; Oc Occultation; Tr Transit of Satellite; Sh Transit of Shadow; D Disappearance; R Reappearance; I Ingress; E Egress. The printing of a phenomenon in *italics* indicates that its visibility is rendered doubtful, either by the brightness of the twilight or by Jupiter's proximity to the horizon.

### Mercury

Is a Morning Star during the first three-quarters of the month, but comes into superior conjunction with the Sun at 3 p.m. on the 27th; and, of course, afterwards travels to the east of him. Mercury is high up in the sky, but, save at the beginning of June, is too near the Sun, and his nearly circular disc subtends too small an angle (a little more than 5″) for him to be either easily picked up or worth looking at when he is found.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 3 3·7 | 14 10·4 | 10 23·5 a.m. |
| 6 | 3 31·6 | 16 38·6 | 10 31·7 ,, |
| 11 | 4 5·0 | 19 14·5 | 10 45·2 ,, |
| 16 | 4 43·9 | 21 40·5 | 11 4·4 ,, |
| 21 | 5 28·2 | 23 33·5 | 11 28·9 ,, |
| 26 | 6 15·8 | 24 30·0 | 11 56·7 ,, |

Hence Mercury, starting from a barren part of Aries, will travel entirely across Taurus, and for a considerable distance into Gemini. He will be in conjunction with Neptune at 7 p.m. on the 5th, and with Saturn at 4 a.m. on the 24th.

### Venus

Is an Evening Star, setting more than an hour after the Sun towards the end of June. Her angular diameter increases from 9·7″ on the 1st to 10·2″ by the 30th, and by the last-named date she has become perceptibly gibbous.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 5 10·1 | 23 17·4 | 0 29·5 p.m. |
| 6 | 5 36·8 | 23 52·3 | 0 36·5 ,, |
| 11 | 6 3·7 | 24 9·6 | 0 43·7 ,, |
| 16 | 6 30·7 | 24 9·1 | 0 50·9 ,, |
| 21 | 6 57·5 | 23 50·7 | 0 58·0 ,, |
| 26 | 7 24·1 | 23 14·7 | 1 4·9 ,, |

The path indicated by the above Ephemeris extends through a good deal of Taurus and right across Gemini. Venus will be to the north of η Geminorum on the 12th, and of μ the next evening. On the 24th she will be 1° 20′ north of δ Geminorum; but these are the only stars of any size to which she will approach moderately near. She will be in conjunction with Saturn (1° 32′ N. of him) at 10 p.m. on the 7th.

### Mars,

For the observer's purpose, continues invisible.

### Jupiter

Now rises and souths in bright sunlight, and to be seen at all must be looked for as soon after sunset as possible, even at the beginning of the month. His diameter continues steadily to decrease from 33·3″ on the 1st to 31″ by the end of June.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 10 3·2 | 13 7·3 | 5 21·8 p.m. |
| 6 | 10 5·5 | 12 54·4 | 5 4·4 ,, |
| 11 | 10 7·9 | 12 40·4 | 4 47·2 ,, |
| 16 | 10 10·5 | 12 25·4 | 4 30·1 ,, |
| 21 | 10 13·3 | 12 9·2 | 4 13·3 ,, |
| 26 | 10 16·3 | 11 52·7 | 3 56·5 ,, |

Starting thus from a point less than 1° north of Regulus, Jupiter will describe a short arc in Leo in a south-easterly direction from that star.

### Saturn

Comes into conjunction with the Sun at 11 p.m. on the 18th, and is hence absolutely invisible.

### Uranus

Is now so rapidly approaching the west, that, like Jupiter, to be seen at all, he must be observed immediately it is dark enough. He is in quadrature with the Sun at 2 a.m. on the 20th. His diameter subtends an angle of 3·8″ during the whole of June.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 11 56·8 | 1 9·7 | 7 15·1 p.m. |
| 6 | 11 56·8 | 1 9·6 | 6 55·4 ,, |
| 11 | 11 56·8 | 1 9·1 | 6 35·8 ,, |
| 16 | 11 57·0 | 1 8·0 | 6 16 2 ,, |
| 21 | 11 57·2 | 1 6·4 | 5 56·8 ,, |
| 26 | 11 57·5 | 1 4·2 | 5 37·4 ,, |

Whence it will be seen that Uranus remains almost sensibly stationary between β and η Virginis.

### Neptune

Is, for the observer's purpose, invisible.

### Shooting Stars

Are rare in June. The nights of the 6th and 20th are those on which indications of showers exist.

### Greenwich Mean Time of Southing of Eight of the Principal Fixed Stars on the Night of June 1st, 1885.

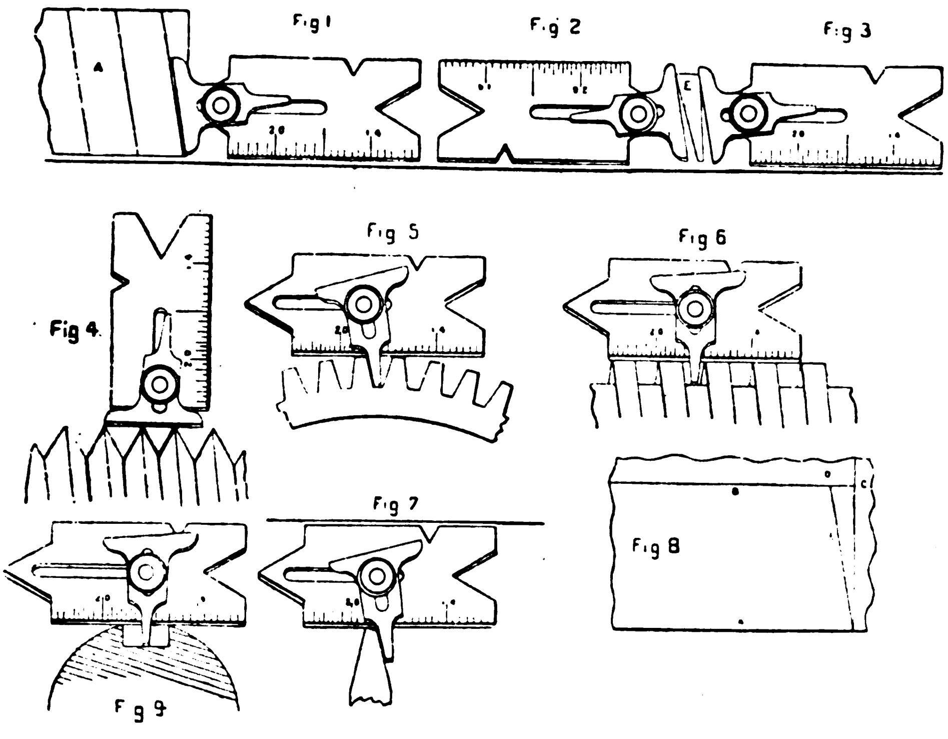
| Star. | Souths. h. m. s. |
|---|---|
| η Ursæ Majoris .. .. | 9 1 1·30 p.m. |
| Arcturus .. .. .. | 9 28 21·59 ,, |
| α Libræ .. .. .. | 10 2 22·76 ,, |
| α Coronæ .. .. .. | 10 47 32·99 ,, |
| α Serpentis .. .. .. | 10 56 18·83 ,, |
| Antares .. .. .. | 11 39 57·54 ,, |
| $\alpha^1$ Herculis .. .. .. | 12 26 51·97 ,, |
| α Ophiuchi .. .. .. | 12 47 0·19 ,, |

The method of finding the Greenwich Mean Time of Southing of either of the Stars in the above list for any other night in June, as also that of determining the local instant of its Transit at any other Station, will be found on p. 356 of Vol. XL.

## THE INTERNATIONAL INVENTIONS EXHIBITION.—IV.

### Prime Movers and Distribution of Power.

THE exhibits in Group IV., Prime Movers, and their numerous accessories, are located for the most part in the South Gallery of the Middle Court; but, as might be expected, some of the most notable of the prime movers are doing useful work in various parts of the Exhibition, and others are employed in giving practical demonstrations of their capabilities in the grounds. Of these the most attractive from the popular point of view are undoubtedly the Mekarski compressed-air tramcar and Mr. Holroyd Smith's electric tramway, both of which, by the time these lines are read, will be in full working order on the railroads laid down outside the buildings in what is called the South Promenade. We have described the Mekarski compressed-air tramcar more than once in previous volumes, and we need only say here that it is one of the best of the schemes for propelling tramcars by a store of compressed air. Tolerably full details of its construction will be found in Vol. XXXVI. p. 63, and there is an account of experimental trips on the Caledonian-road in Vol. XXXVII. p. 485, while there are general articles in Vol. XXXIV. p. 245, and Vol. XXXIII. p. 2. This exhibit serves to display the merits of several inventions, for besides the car itself, the "permanent way" illustrates the Denham-Olpherts-Molesworth system, and the air-compressing engines give a practical demonstration of the capabilities of the Northcott devices as made by the General Engine and Boiler Co., of the Hatcham Ironworks, S.E. The steam-engine is fitted with a simple and novel form of governor, consisting of two pieces of chain kept taut by a spring on the governor spindle. As the speed increases, the chains tend to assume curves, and thus actuate the throttle valve. A house has been erected, in which the tramcar receives its store of power, and the line itself being laid with a rather sharp double curve is sufficient to test the running power of the car on the level, though it would have been more satisfactory if a hill or two could have been introduced. However, the exhibitors have done the best they could with the means at their disposal, and they demonstrate in a satisfactory manner that, so far as mechanical considerations are concerned, a tramway can be driven by means of compressed air. In this connection the question is simply one of economy, and admitting the advantage of compressed air in the shape of complete avoidance of smoke and noise, it may be doubted whether it will successfully compete with steam applied direct. The Mekarski system, it will be remembered, has been at work for some years in Nantes, and all the little difficulties have been overcome, the "hot pots" for warming the air effectually checking the tendency to freeze up. Mr. Holroyd Smith's electric tramcar, working on the system which is being put into working order on a considerable length of line at Blackburn, was ready on Saturday last, and will undoubtedly attract much attention; but at present there is no sign of Rammell's pneumatic railway on the impulse system, although Messrs. Walker Bros., of Wigan, are ready with the fine air-compressing machinery, a specimen of which is shown at their stand in the Middle Court. In the grounds forming the South Promenade Messrs. Dick, Kerr, and Co. show their portable railway and rolling stock, the little side-tank locomotive being fitted with Morton's valve-gear. The South-Eastern Railway Co. exhibit a coal truck and a goods waggon specially constructed for express speed—a class of traffic this company is largely developing in connection with the Continent. In the buildings themselves the best exhibit of prime movers is probably that of the gas-engines—at least, they present the greatest novelties. Messrs. Crossley Brothers, of Openshaw, besides the engines on loan and used for various purposes by other exhibitors, show at their stand a 7 h.p. of new design, with the self-starting arrangement; but their principal novelty is the double-cylinder engine of 4 h.p., specially designed for electric-lighting purposes, where steadiness of running is a desideratum. This engine has an impulse at every revolution, and the charge of gas is automatically increased or decreased as required. An incandescent electric lamp is, in fact, an excellent tester of steady running in a gas-engine, as it indicates every impulse by slight changes in the incandescence. A new vertical model is also shown by Messrs. Crossley, which will attract much attention from those who require about 1 h.p. It is ¾ h.p. nominal, and is notable for the small space it needs. Engines of the well-known pattern are to be seen driving printing machines, dynamos for electro-plating, hoisting apparatus, the Aquarium pumps, &c. The British Gas Engine and Engineering Co. exhibit Atkinson's well-known gas-engine, and an entirely new and novel pattern, which it is almost impossible to describe without engravings. Two bent lever arms pivoted in the centre are connected at their upper ends by links to the crank-pin, while the lower ends are attached to plain plunger pistons, working in a horizontal cylinder at the foot of the casting. There is no valve gear and no slide, the pumping piston and the working piston by their peculiar differential action covering and uncovering the passages for the supply, exhaust, and ignition, an impulse being, of course, given at each revolution. The ignited charge is expanded to about double its volume; but a feature of special interest is the rapidity with which the power is developed, thus reducing the loss of heat to the water jacket. Andrew and Co., of Stockport, show the small Bisschop engine, and the more recent Stockport pattern, which runs with much steadiness, as shown at work. Sterne and Co., of Glasgow, exhibit a Clerk engine with self-starting gear, the principle of which was fully described in No. 1011. Amongst other engines the Körting, exhibited by Körting Bros., of Pancras-lane, E.C., is shown running; but although it is without slides, it has too much gear about it to commend it to the mechanic. It, however, occupies but little space. The Withers gas-engine, exhibited by Beynon and Cox, of Torquay, is a simple vertical, actuated by a single piston valve operated by a cam, which instantaneously opens the port and closes it as quickly, thus insuring a full charge. The consumption of gas for a 1 h.p. engine is stated to be 44 cubic feet per hour, an explosion taking place at every revolution. Statements about the consumption of gas per i.h.p. are, however, not of much value, and the jury would do a useful piece of work if before making their awards they tested the relative economy of the different engines. Another simple vertical engine is one shown by Mr. R. Skene, of Wickham-street, S.E. The simplest gas-engine is exhibited by Edwards and Co., of Southampton-buildings, for apparently it has no gear at all; but as it is not shown in motion, it is impossible to form any opinion of its merits. Clarke and Gillespie, of Stevenage, exhibit a small engine of 2-man power called the Syrinx, which is certainly compact, and there are some others of no particular importance, but which help to make a tolerably complete collection, from which the buyer will have some difficulty in making a selection. Hot-air engines are shown by Hayward Tyler and Co.; Bailey and Co., of Salford; and by the Britannia Company. The first-named exhibit the Rider engine, but Messrs. Bailey have a very compact vertical, on Lehmann's patent, the horizontal type of which we illustrated in No. 794. In this engine the expanded air is cooled by water, and immediately returned to the heating chamber. The Britannia Company have two small hot-air engines, one driving a lathe; but those are suitable only for gas, while the Rider and that exhibited by Messrs. Bailey, though working by gas, are adapted for burning any kind of fuel. Of steam-engines the chief novelties are in connection with the valve-gear, though the compound tandem triplex of Goodfellow and Matthews will be new to many visitors. It has three sets of cylinders arranged radially round the crank-shaft, each set consisting of a large and small cylinder, through both of which steam passes in succession. The pistons are in the form of plungers of two diameters, the smaller portion working in the high-pressure cylinders, and all three coupled to one crank. One eccentric and strap, working valves of the piston type, distributes steam to all six cylinders. Three of these engines are at work driving dynamos, work for which they are specially designed. The Willans engine as applied in launches is exhibited at work in the Middle Court, and in the electric lighting shed driving a dynamo. A curiosity amongst these new high-speed engines is the Parson's four-cylinder exhibited by Kitson and Co., of Leeds, for not only does the crank-shaft revolve, but the cylinders rotate around the shaft at half the velocity of the latter. It is impossible to give any idea of this engine without drawings. Mr. Bumsted, of Hednesford, exhibits Chandler's high-speed engine, which is capable of driving dynamos direct up to 1,200 revolutions. The engine is of the type in which the piston is of the hollow plunger pattern, coupled direct to the shaft by one rod, and is thoroughly lubricated by the crank pin itself revolving through oil at each turn. The engine is shown driving a dynamo at 1,500 revolutions by rope gearing, running itself at 750. Heenan and Froude exhibit the Tower spherical engine coupled to a Crompton dynamo. A model in wood will help the visitor to understand this altogether novel and ingenious device, which it is difficult to explain even with the help of diagrams. Amongst the steam engines in the Middle Court which are shown in motion, that exhibited by D. Adamson and Co., of Dukinfield, will attract attention. It is a Wheelock automatic cut-off engine, with 16in. cylinder and 3ft. stroke. The steam passages are at the bottom to insure thorough drainage, and at each end is a bored chamber filled with a partially rotating valve, which acts like an ordinary slide-valve, placing the passage in connection with either the steam or the exhaust. Between the main-valve chambers is a central steam chamber fitted with cut-off valves, which give a free opening with very small movement. No steam can leak into the exhaust without passing both cut-off and main valves. Mr. Ogden, of Ashton-under-Lyne, also has an attractive exhibit in the shape of a "Manchester" automatic expansive engine, which is shown running. The cylinder is simply a pipe with flanges. The valves, steam, exhaust, and cut-off, are independent of each other, and can be adjusted; the grade of cut-off from no steam to three-quarter stroke is under the control of the governor. The Corliss gear is silent and simple. Marshall and Co., of Nottingham, Hornsby and Sons, of Grantham, and Robey and Co., of Lincoln, exhibit splendid specimens of the semi-fixed compound engines, which have found so much favour during recent years. In the case of Robey's engine, it is fitted with Richardson's patent electric regulator for maintaining a constant electric current on a circuit. An electro-magnet acts upon a heavy armature, which is attached to a lever that operates a steam valve, so that in the event of an accident to the lamps, the steam would be shut off, or the speed reduced in proportion to the number of lamps cut out. This engine is shown driving the exhibit of the Kirkstall Forge Company, consisting of their rolled shafting. Specimens are shown in all sizes, from $\frac{5}{16}$in. to 6in., and 20ft. long, and they are rolled so straight, round, and true that no turning is required. Couplings and adjustable bearings are shown in connection. For this shafting an increase of 20 per cent. in torsional strength, and 33 per cent. in flexional strength is claimed. Duncan Brothers, of Queen Victoria-street, exhibit a compound non-condensing launch engine, with Bremme's patent valve-gear for expansion and reversal, a simple arrangement which has replaced the ordinary link-motion in many cases. Howard Lane and Co., of 115, Palmerston Buildings, E.C., exhibit the Lane sectional steam boiler, and a model cylinder boiler with their interior electric lamp fittings for observing the action while at work. The eyepiece is a fitting containing two pieces of glass, and the incandescent lamp is fitted into a bulb of thick glass. A Root sectional boiler is shown close by, and Galloway and Sons, of Manchester, exhibit a boiler similar to those at work, with portions of the sides removed so that the scum troughs and anti-priming pipe can be seen. Durham, Churchill, and Co., of Leadenhall-street, exhibit specimens of their well-known velometers, and a compound spiral piston packing which is so arranged that the rings will expand only to a certain extent, no matter how tightly screwed up. The packing consists of a series of spirals connected together by short lengths of straight wire, instead of a continuous spiral all round the piston. The Venetian Air-valve Furnace Bar Co., of Walbrook, exhibit Galley's movable angled feather furnace bars, and the Rocking Fire Bar Syndicate also exhibit their fire bars with automatic rocking apparatus. Several firms show applications of friction driving gear for working dynamos, and Prof. J. A. Ewing also exhibits a model of his system of gearing by which power is transmitted by rolling friction. Prof. Fleeming also illustrates by a large model his nest gearing, as it is called, which transmits power by rolling friction between drums so arranged as to relieve the bearings of direct pressure. We described this invention on p. 338, Vol. XXXIX. Mr. Hindley, of Queen Victoria-street, shows several examples of his portable steam-engines specially adapted for small power users; and Mr. J. Brady, of Rudgwick, Sussex, shows a light combined traction and stationary engine, weighing 34cwt., which is entirely under the control of one person. It has two cylinders, and is carried on three wheels; but we should like to see it at work on rough roads before expressing an opinion of its merits as a traction engine. Mr. R. M. Marchant, of Fenchurch-street, was, at the time of our visit, erecting the plant to exhibit his system of returning the exhaust to the boiler, and when at work it will doubtless attract some attention as an attempt to use steam in the complete circle, which, it must be confessed, is not considered economically feasible by engineers generally. Mr. Kirkaldy, of West India Dock-road, asks the attention of engineers and mechanics to his remarkably small surface condensers containing spiral coils of cold-water pipes, which are certainly remarkably efficient. Injectors, speed indicators, and recording instruments are shown by several firms, some of them at work in connection with the various boilers and engines, particularly in the electric-lighting shed, and the numerous steam-pipes connected to the various engines are in all cases coated with some of the non-conducting compositions; Leroy and Co., of Gray-street, E., having also at their stand a variety of exhibits showing what can be done with their composition, and a special manufacture, which is sufficient when only one inch thick. Pulleys are shown by several firms, those most noticeable being the light varieties made of steel and wrought iron, and those with perforated faces, which are supposed to enable the belt to take a firmer grip. Belting is shown in great variety, both at the stands of the exhibitors and driving various machines; there are also some belt fasteners, but nothing very novel in character. Boiler feeders are exhibited in model and full size, Fromentin's being on view in the shape of drawings and model at Stand No. 470, while mechanical stokers are represented in full size, but so far as we have been able to discover none of the boilers at work is fitted with one. There is undoubtedly much prejudice against mechanical stokers; but an examination of those exhibited will show that there is no reason why fuel should not be automatically fed to a steam-boiler. Lubricators are exhibited at the stands, and also in great variety on the different engines and machines—Trier Brothers showing a good collection of Stauffer's devices, with Akaiser's mechanism for obtaining step-by-step rotary motion in numerical counters for machinery. Mr. D. Joy exhibits a moving cardboard model of his gear, two sets operating the three valves of a triple engine, and a quadrant block from a L. and N. W. goods engine which has made 48 million revolutions. H. and T. C. Batchelor, West Kensington, show one of their patent "motion drawings" in the shape of the engines of the Atlantic liner *America*. These drawings are on cardboard, cut out and laid over one another, so that the parts can be moved to various positions of the motion. This group embraces so many exhibits of interest, that it is scarcely possible in the available space to do much more than indicate what is to be seen; but it contains exhibits which properly come under other heads.



## WYKE'S SCREW-CUTTING GAUGE.

These gauges are made by J. Wyke and Co., East Boston, Mass. The engravings, with the following description, will explain the uses of the tool:—To get the rake of thread of any pitch whatever, take a piece of sheet metal (or other material) Fig. 8, with one edge A true. Then lay off a line B, the same distance from the edge A, as the diameter of the screw to be cut. Then draw line C at right angle with edge A. Then from line C, on line B, measure off half the pitch D, and draw line E, which will be the angle or rake required for the tool. Set the gauge as shown in in Fig 1. When the gauge is set to the line as shown Fig. 1, it is then set to use when making tool, and is applied to both sides as shown in Figs. 2 and 3. E represents the tool with clearance allowed. When the gauge is set to the rake of any right hand thread, by simply turning it over on the other edge it become set for left hand. When cutting V-threads, the gauge can be used for grinding angle of tool (60°) and setting the tool square on rest; also for depth and for testing accuracy of thread. When testing accuracy of thread, set the gauge down in the thread as shown in Fig. 4. Then reverse the gauge, and if the thread is not correct it will be seen at once. This can be done before the screw is quite finished, thus giving time to finish correctly. When cutting bastard threads, the gauge can be used for depth angle of thread, and setting tool correctly on rest as shown in Figs. 5 and 7. (The line represents the bar in the lathe, and the tool is supposed to be in the rest.) Also, for testing whether the thread be perpendicular to the axis of the screw. When cutting worms to suit gears, set gauge as shown in Fig 5. It is then set for depth of thread, also for testing thread and setting tool correctly on rest. When cutting square threads, set the gauge to half the pitch by scale, and you have the depth required as shown in Fig. 6. The gauge can be used for taking all depths of the Franklin Institute Standard threads, also standard worm threads from the regular standard gauges. It can be used for getting equal clearance when making cutting-off tools, and as a depth gauge when cutting gears, drilling and planing out key seats, &c., as shown in Fig. 9; also as a depth and angle gauge for many purposes. These gauges are made in two sizes. No. 1 has a graduated scale 2in. long, and can be used for all threads up to ¾in. pitch. No. 2 has a graduated scale 3in. long, and can be used for all pitches from ¾in. to 2½in. pitch, or for other purposes, as mentioned.—*American Machinist.*

## THE WAVE THEORY OF LIGHT.

By Prof. Oliver Lodge.

In a recent issue of the *Engineer*, under the head "A Scientific Mistake," is an article asking a question, an answer to which it is easy to give. The writer says he will be gratified by hearing that unsoundness in the wave theory of light has been admitted by teachers or writers of textbooks. To a certain extent I am able to gratify him, then; for, though I cannot answer for all teachers or text-books, I can assure him that the wave theory of light has been felt to be unsatisfactory ever since its inception at the beginning of this century. To call it "unsound" is too strong; to call it "unsatisfactory" is what all good teachers are, I believe, accustomed to do every time they expound it. Let me explain the difference. A wave theory of light is certainly and demonstrably true. That is to say, light does consist of waves. But what does one mean by a wave? A hump on the top of the sea? That is one kind of wave, and by no means a very simple kind, but it is scarcely the kind that constitutes light. But what does one mean by a wave? An oscillation or vibration of some form of matter? Not necessarily. What then? A periodic disturbance? Yes, a disturbance of a medium *periodic both in space and time.* Note the definition. Now light indubitably is periodic in space and time, and hence it is a wave motion. So far all is certain; and from this certainty alone a host of facts, diffraction, &c., &c., are instantly explicable. But now, when we try to go further, and to ask what is moving, and with what sort of motion, we are landed in many difficulties; and progress is impeded, either by want of hypothesis altogether, or by cumbrous and artificial ones. The natural early view was that the wave motion was a material motion just like motions to which we were accustomed in sound and other of the more tangible phenomena, although minute beyond ordinary recognition. This mechanical view of the wave theory, as an actual bodily oscillation of some jelly-like substance seems to me doomed. With great ingenuity it can be made to account for a multitude of the facts, and it apparently numbers among its present adherents the magnificent name of Sir William Thomson. I venture to think, nevertheless, that it will be abandoned; and the periodic disturbance which constitutes light will be sought, not in the mechanical oscillation of ordinary matter, but in the subtle oscillation of the electric medium as conjectured, and more than half-verified, by Clerk-Maxwell. Calling a disturbance "electrical" instead of "mechanical" is rather like calling a phenomenon "chemical" instead of "physical," when we mean to say we do not understand it; but such a statement means more than simply saying we do not understand it—it relegates light to a host of more or less familiar phenomena with which every day we are becoming better acquainted; it marks its relationship and family in the general body of knowledge; and it gives us the assured hope that as soon as the nature of electricity is better and more intimately known, then will the nature of a wave of light also begin to be clearly and definitely intelligible.

## TWO NEW TYPE-WRITERS.

Two new type-writers have recently been introduced to notice. One, the invention of Mr. E. Peacock, a journalist, is a portable type-writer and manifolding machine. The "dial" type-writer consists of a small brass cylinder 4½in. diameter and 2½in. high, the top forming a dial around which are engraved two circles of characters, the outer circle comprising the capital letters of the alphabet and the numerals, and the inner circle the small letters, signs, and quotation and punctuation marks. Corresponding types are carried radially in two horizontal circles within the cylinder, and by pressing a small lever either set can be brought into play. Around the edge of the dial are a series of countersunk holes corresponding to the letters against which they are radially placed. Attached to a spindle in the centre of the dial, and revolving about it like the handle of a domestic coffee-mill, is a short lever, on the under side of the outer end of which is a pin, which fits into the holes formed around the rim of the dial. Upon this lever being depressed over any letter or figure it causes a corresponding type to be smartly projected horizontally through a small aperture in the cylinder. Inking rollers are provided on either side of this opening, and, the types having been inked in passing them, impressions are made on the paper, which is carried on a roller in front of the striking point. This roller is traversed automatically from left to right, and when the end of a line is reached the roller and paper are sent back by touching a small stop, which also causes the roller to turn partially round, thus presenting a fresh surface of the paper for the next line. By depressing another small stop spaces are made between the words. In this way the machine prints a single copy on ordinary paper, but by the use of tissue paper and carbonic sheets placed alternately it is stated that as many as 20 perfectly legible impressions can be produced at once.

Another, the invention of Messrs. T. G. and H. Daw, consists of a series of levers carrying at their outer ends the printing types, both letters and figures. These levers are arranged in a circle about 7in. in diameter, and are actuated by piston-keys or plungers placed above them in two concentric circles. Upon a piston being depressed by the finger the type connected with it is sharply brought from the vertical to the horizontal position, each type striking a point central to the circle formed by the whole; one type only can therefore be in effective operation at one time. The types are similar to those used in printing—that is, they are the reverse of the letter or figure produced, as the impression is formed on the under side of the paper on which they strike. This paper is carried on a cylinder around which carbonic paper is first wrapped. The cylinder is automatically capable of rotation around its axis, and of a horizontal movement under the point where the types strike. The step-by-step rotation takes place as each type is imprinted on the paper, a similar step-by-step horizontal movement taking place at the end of each line. As each sheet of paper becomes covered with writing it is automatically thrown off from the roller, the latter being at the same time returned to its normal position ready for a fresh sheet of paper. On this being placed on the roller the machine is ready for the next start. By using several sheets of paper and placing carbonic sheets between them it is stated that six copies can be produced at the same time. The type requires no cleansing, as the paper is struck on the reverse side to the colouring matter, which latter can be easily renewed from a roll of carbonic paper placed within the cylinder.

## THE COLOURING MATTERS OF FLOWERS AND FRUITS.

A very interesting communication has recently appeared in the *Verhandlungen der Physik Med. Gesellschaft zu Wurzburg* on the subject of the colouring matter in flowers and fruits, contributed by Dr. A. Hansen. It appears that a relatively small number of pigments serves for the production of the seemingly endless variety of colour in flowers and fruits. The white and black shades which we encounter there are not due to any special colouring matter. White is due merely to the reflection of light through colourless tissues containing air. Blacks owe their origin merely to the dense concentration of violet pigments. If we set aside chlorophyll green, which is rarely met with in flowers, we may recognise the three following groups of colours:—(1) Yellows, (2) reds, (3) blues and violets. Hildebrand has previously demonstrated that the yellows are mostly in combination with the plasmic substance, whilst the colours of the second and third group are generally found existing in the cell-sap. The yellow of flowers forms an insoluble compound with fatty matters, as was demonstrated by Krukenberg in the animal kingdom under the name of lipochrome (this may go far to account for the general comparative permanence of the yellow colours both of plants and animals). The yellow pigment, obtained by Hansen in a pure crystalline state by saponification with soda and extraction with petroleum ether, agrees in its behaviour with lipochromes. The spectra of the pigments of different yellow flowers agree with each other so closely as to lead to the conclusion of their mutual identity. Between the F and G lines there occur two absorption bands, which do not, however, always occupy exactly the same position. The solutions are not fluorvescent. Orange is formed by a denser deposit of the yellow pigment. Thus the colour of the rind of an orange is due to the same pigment as is found in the yellow flowers of *Ranunculus repens* (butter-cup, king-cup). The colour of yellow dahlias and of lemon rind is not a lipochrome. It is soluble in water, and behaves differently both chemically and spectroscopically, displaying, for instance, no absorption bands. It is very similar to the pigment of *Æthalium septicum* (the yellow fungus or mould on rotten wood) examined by Krukenberg.

The reds of flowers may be reduced to a single pigment—the rose-dye of roses, carnations, peonies, &c. It is soluble in water, and is decolourised in alcohol, probably in consequence of dehydration. On the addition of an acid the colour is restored. The spectrum displays a broad absorption-band between D and F. The varying intensity of the colours of roses, carnations, and peonies depends probably on the presence of acids. The scarlets and brick-reds of poppies, scarlet lilies, the berries of the dog-rose, &c., are produced by the simultaneous presence of lipochrome.

The blue and violet pigments turn pale also in alcohol. The solution is reddened by the addition of an acid, as was noticed by Fremy and Marquardt. They assumed, therefore, that the red colours were merely blue pigments modified by acids. Hansen, on the other hand, holds that the blue and violet colours are derivatives of the red. In favour of this view is the fact that certain blue and violet flowers (*Boragineæ*) are at first red. The flowers of *Erica cinerea* (pine-leaved heath) are on opening red, but turn more to a violet on fading. On the contrary, the corolla of many fuchsias passes from a bluish violet to a red. Salts of iron turn the red of peony flowers to a violet. It is well known that gardeners can produce blue Hortensias by adding iron to the soil. Peony red is turned to a violet by the addition of sodium phosphate, and larger quantities of the same reagent render it blue. The spectrum of the blue and violet pigments has two absorption bands between D and *b*. These pigments also may be combined with lipochrome yellow, they producing the colour of the berries of *Ampelopsis* (Virginian creeper). Hansen does not refer to the red, blue, and violet colour granules which occur here and there in flowers and fruits. He assumes, therefore, only four fundamental pigments—soluble yellow, lipochrome yellow, flower-red, and chlorophyll green. He opposes the view that all colours are derived from chlorophyll green, since their specia do not agree. The change of colours of green fruits and green leaves in autumn he accounts for by the destruction of the chlorophyll, and either the simultaneous formation of new pigments, or the unmasking of lipochrome which existed previously, but which was concealed by the chlorophyll. Brown decomposition products co-operate in the production of the autumnal colours.

## ELECTROTYPING.

THIS eminently useful application of the art of electrotyping originated with Volt, Cruickshank, and Wollaston about 1800 or 1801. In 1838, Spencer, of London, made casts of coins and cast in intaglio from the matrices thus formed; in the same year Jacobi, of Dorpat, in Russia, made casts by electro deposit, which caused him to be put in charge of the work of gilding the dome of St. Isaac at St. Petersburg. Electrotyping for the purposes of printing originated with Mr. Joseph A. Adams, a wood-engraver of New York, who made casts (1839-41) from woodcuts, some engravings being printed from electrotype plates in the latter year. Many improvements in detail have been added since, in the processes as well as the appliances. Robert Murray introduced graphite as a coating for the forme moulds. He first communicated his discovery to the Royal Institution of London, and afterwards received a silver medal from the Society of Arts.

### Blackleading the Forme.

The process of electrotyping is as follows: The forme is locked up very tightly, and is then coated with a surface of graphite, commonly known as blacklead, but it is a misnomer. This is put on with a brush, and may be done very evenly and speedily by a machine in which the brush is reciprocated over the type by handwheel, crank, and pitman. A soft brush and very finely powdered graphite are used; the superfluous powder being removed, and the face of the type cleaned by the palm of the hand.

### Taking the Mould.

A shallow pan, known as a moulding pan, is then filled with melted yellow wax, making a smooth, even surface, which is blackleaded. The pan is then secured to the head of the press, and the forme placed on the bed, which is then raised, delivering an impression of the type upon the wax. The pan is removed from the head of the press, placed on a table, and then built up, as it is termed. This consists in running wax upon the portions where large spaces occur between type, in order that corresponding portions in the electrotype may not be touched by the inking roller, or touched by the sagging down of the paper in printing.

### Making the Deposit.

The wax mould being built, is ready for blackleading, to give it a conducting surface upon which the metal may be deposited in the bath, superfluous blacklead being removed with a bellows. Blacklead, being nearly pure carbon, is a poor conductor, and a part of the metal of the pan is scraped clean, to form a place for the commencement of the deposit. The back of the moulding is waxed, to prevent deposit of copper thereon, and the face of the matrix is wetted to drive away all films or bubbles of air which may otherwise be attached to the blackleaded surface of the type. The mould is then placed in the bath, containing a solution of sulphate of copper, and is made a part of an electric circuit, in which is also included the zinc element in the sulphuric acid solution in the other bath. A film of copper is deposited on the blacklead surface of the mould, and when this shell is sufficiently thick it is taken from the bath, the wax removed, the shell trimmed, the back tinned, straightened, backed with an alloy of type-metal, then shaved to a thickness, and mounted on a block to make it type-high.

A recent improvement has been introduced, in which there is added finely pulverised tin to the graphite for facing the wax mould: the effect in the sulphate of copper bath is to cause a rapid deposition of copper by the substitution of copper for the tin, the latter being seized by the oxygen, while the copper is deposited upon the graphite. The film is after increased by the usual means. Knight's expeditious process consists in dusting fine iron filings on the wet graphite surface of the wax mould, and then pouring upon it a solution of sulphate of copper. Stirring with a brush expedites the contact, and a decomposition takes place; the acid leaves the copper and forms with the iron sulphate a solution which floats off, while the copper is freed and deposited in a pure metallic form upon the graphite. The black surface takes on a muddy tinge with marvellous rapidity. The electric-connection gripper is designed to hold and sustain the moulding pan and make an electric connection with the prepared conducting pan of the mould only, while the metallic pan itself is out of the current of electricity, and receives no deposit.

### Backing-up.

The thin copper-plate, when removed from the wax mould, is just as minutely correct in the lines and points as was the wax mould and the original page of type. But it is obvious that the copper sheet is no use to get a print from. You must have something as solid as the type itself before it can be reproduced on paper. So a basis of metal is affixed to the copper film, and this again is backed up with wood thick enough to make the whole type-high. To get this, a man melts some tinfoil in a shallow iron tray, which he places on the surface of molten lead, kept to that heat in square tanks over ordinary fires. The tinfoil sticks to the back of the copper, and on the back of this is poured melted type-metal, until a solid plate has been formed, the surface of which is the copper facsimile and the body white metal. The electro metal plate, copper coloured and bright on its surface, has now to go to the finishing-room.

Here are two departments. In one the plates are shaved and trimmed down to fit the wood blocks, which are made in the other department. Some of these operations are done by hand, but it is very interesting to see self-working machines planing the sheets of metal to precisely the required thinness with mathematical exactness. A pointed tool is set to a certain pitch, and the plate of metal is made to revolve in such a way that one continuous curl shaving falls until the whole surface (back) has been planed perfectly true. The wood blocks are treated in the same way, after being sawn into the required sizes by a number of circular saws. Another set of workmen fit and join the metal to the wood, trim the edges, and turn the blocks out type-high and ready for working on the printing press.

### A Wet Blackleading Process.

In Messrs. Harper's establishment in New York, an improved wet process of blackleading is adopted. The wax mould is laid face upward on the floor of an inclosed box, and a torrent of finely pulverised graphite suspended in water is poured upon it by means of a rotary pump, a hose, and a distributing nozzle which dashes the liquid equally over the whole surface of the mould. Superfluous graphite is then removed by copious washing, an extremely fine film of graphite adhering to the wax. This answers a triple purpose; it coats the mould with graphite, wets it ready for the bath, and expels air bubbles from the letters. This process prevents entirely the circulation of blacklead in the air, which has heretofore been so objectionable in the process of electrotyping.

### A New Foreign Process.

The galvanoplastic process of M. Coblence for obtaining electrotypes of wood-engravings is as follows: A frame is laid upon a marble block, and then covered with a solution of wax, colophane, and turpentine. This mixture on the frame, after cooling, becomes hard, and presents a smooth, even surface. An engraved wooden block is then placed upon the surface of the frame and subjected to a strong pressure. The imprint on matrix in cameo, having been coated with graphite, is then placed vertically in a galvanoplastic bath, and a cast, an exact reproduction of the wood-engraving, is obtained. The shell is then backed with type metal and finished in the usual way.—*Printer and Stationer.*

## SCIENTIFIC SOCIETIES.

### ROYAL METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this Society was held on Wednesday evening, the 20th inst., at the Institution of Civil Engineers, 25, Great George-street, Westminster; Mr. R. H. Scott, F.R.S., President, in the chair.

Dr. H. Dobell and Mr. J. N. Longden were elected Fellows of the Society.

The following papers were read:—(1) "The Temperature Zones of the Earth considered in Relation to the Duration of the Hot, Temperate, and Cold Period, and to the Effect of Temperature upon the Organic World," by Dr. W. Koppen, Hon.Mem.R.Met.Soc. (2) "Velocities of Winds and their Measurement," by Lieut.-Col. H. S. Knight, F.R.Met.Soc. The author, after describing the various ways of ascertaining the direction and velocity of the wind, makes several suggestions for the improvement of Robinson's anemometer. (3) "On the Equivalent of Beaufort's Scale in Absolute Velocity of Wind," by Dr. W. Koppen, Hon.Mem.R.Met.Soc. The author refers to Mr. E. Harding's paper read before the Society in December last on the anomalies in the various wind velocities given by different authors as equivalents for the numbers in Beaufort's scale; and, as illustrating the point, calls special attention to the want of agreement between the velocities obtained by Mr. Scott and those subsequently obtained by Dr. Sprung and confirmed by himself. (4) "Note on a Peculiar Form of Auroral Cloud seen in Northamptonshire, March 1st, 1885," by the Rev. James Davis.

**Atmospheric Electricity.**—Professor Palmieri, of the Vesuvian Observatory, has recently published some observations of interest on atmospheric electricity. In clear weather the atmospheric electricity is usually positive, if negative a downfall of rain, &c., may be inferred to be going on at some little distance. There is a maximum of atmospheric electricity at 9 a.m., another soon after sunset, which often continues during a great part of the night. A minimum takes place before daybreak, and another in the afternoon. This periodicity is, however, disturbed by atmospheric movements. When the maxima are very pronounced, cloudy weather often follows. If the sky becomes overcast the electric indications grow stronger, and if at the time of the evening maximum the relative moisture increases with a heavy dew, maxima of special duration and intensity may be expected. The assumption that atmospheric electricity becomes stronger with altitude is not borne out by the Vesuvian observations. Lower potentials are generally observed on hot summer days; in spring and autumn the indications are stronger; in winter they are uncertain. On cloudy days the potential is less intense, but positive; during rain the potential increases. A rain zone is positive but surrounded by a negative zone, which again is surrounded by a zone of positive electricity. According to Palmieri, there is no thunder and lightning without rain.—*Engineering.*

**To Clean Marble.**—Brush the dust off, then apply with a brush a good coat of gum-arabic about the consistency of thick mucilage, and expose it to the sun or wind to dry. In a short time it will peel off. If all the gum should not peel off, wash it with clean water and a clean cloth. If the first application does not have the desired effect it should be tried again. Another method is to rub the marble with the following solution: ¼lb. of soft soap, ¼lb. of whiting, and one oz. of soda, and a piece of stone blue the size of a walnut; rub it over the marble with a piece of flannel, and leave it on for twenty-four hours, then wash it off with clean water, and polish the marble with a piece of flannel or an old piece of felt; or take two parts of common soda, one part of pumice-stone, and one part of fine-powered chalk, sift it through a fine sieve, and mix it with water, then rub it well over the marble, then wash the marble over with soap-and-water.

# SCIENTIFIC NEWS.

AMATEUR astronomers all the world over, and our readers in particular, will regret to hear of the death of the Rev. Thomas William Webb, M.A., which took place last week after a short illness. Mr. Webb graduated at Magdalen Hall, Oxford, taking his bachelor's degree as second class in mathematics in 1829. He was admitted to priest's orders in 1831, and after having held a minor canonry and the precentorship of Gloucester Cathedral with sundry curacies, he was instituted to the vicarage of Hardwick in 1856, and made the name of that place famous as the residence of the author of "Celestial Objects for Common Telescopes." A few years ago Mr. Webb was appointed a prebendary of Hereford Cathedral; but it is as a contributor to the records of observational astronomy that he will be most widely remembered, for we suppose there are few owners of telescopes who, reading the English languago, have not Webb's "Celestial Objects" in their library. Mr. Webb joined the Royal Astronomical Society in 1852, and had, we believe, completed his 78th year.

A portrait-medallion of the late Mr. Peter Squire was last week unveiled in the Pharmaceutical Society's house in Bloomsbury-square by Sir Spencer Wells, Bart., in the presence of a notable gathering of members of the medical profession. To Mr. Squire we are mainly indebted for the British Pharmacopeia, and when anæsthesia was first practised in this country he constructed the apparatus used in the initial operation—apparatus which is now in the Museum of University College. Mr. Squire was one of the founders of the Pharmaceutical Society, three times president, and for 27 years its examiner in botany.

The success achieved by MM. Henry in the production of star-charts by photography with the aid of provisional apparatus, determined Admiral Mouchez, director of the Paris Observatory, to grant the requisite order for a large instrument specially constructed for the work. The results of some preliminary trials with this apparatus have been recently reported to the Academy of Sciences, Admiral Mouchez expressing the opinion that the problem of constructing celestial charts, including all stars down to the 15th magnitude, is now solved. The minimum times of exposure required to secure impressions of stars visible to the naked eye vary from ·01 to ·5 of a second; for 12th magnitude stars, 2m.; and for the faintest stars obtained (15th and 16th magnitude), 1h. 30m. The images are perfectly distinct, about 2,800 stars being discernible on one plate of 0·25m. surface. The report on the observatory for 1884 contains a chart of part of Perseus, reproduced from the photographic plate by heliogravure. MM. Henry have, we believe, obtained the best results with gelatino-bromide plates.

M. Stephan contributes to No. 2661 of the *Astronomische Nachrichten* a catalogue of places of 100 new nebulæ discovered and observed at Marseilles during the last two years. The places are given with great accuracy for the epoch of 1885, and short descriptive notes referring to brightness and form accompany them. This list continues that published in No. 2502, which contains 96 nebulæ discovered in 1879-82.

The dome for the observatory erected by M. Bischoffsheim at Nice is finished, and will presumably be in place shortly. The dome will rest on water carried in a trough round the observatory room, the edge of the dome being shaped so as to form a reservoir for air—a plan said to be so perfect that one person will be able to move the great weight completely round the horizon. There is a risk of the water freezing, but frosts are rare in Nice; still, experiments are to be made shortly, and in view of the effects of corrosion with salted water it is probable that some other floating medium will eventually be adopted. The dome is 22m. diameter—a little more than 72ft.

The subject of the address which Prof. W. Grylls Adams will deliver during the forthcoming meeting of the British Association is the "Electric Light and Atmospheric Absorption."

The statue of Darwin by Mr. Boehm has been placed in the great hall of the Natural History Museum. South Kensington, and will be unveiled early in June by the Prince of Wales.

The Fishmongers' Company have made a grant of £2,000 to the Marine Biological Association—£1,000 to be paid this year, and £200 per annum for the next five years.

Mr. F. O. Bower, the lecturer on botany at South Kensington, has been appointed to succeed Prof. Bayley Balfour in the regius chair of botany at Glasgow.

Dr. Kleiber, of St. Petersburg, has published the results of the investigations made by himself and Dr. Keller as to the augmentation of the earth's mass by meteors reaching it from space. On an average it is said that a single observer will see about 10 meteors per hour. A single observer, however, does not command the whole of the sky above his horizon—actually only about 23 per cent. of it; but combining a series of separate deductions, it would appear that about 450,000 meteors fall on the surface of the whole earth each hour. The average weight of a meteor, it is shown, may be taken at five grammes; whence it follows that the earth receives hourly not less than 4,960lb. of foreign material.

In a congregation held at Cambridge University last week, it was resolved to raise by way of loan the sum of £70,000 for the erection of the proposed new chemical laboratory and the Sidgwick Geological Museum.

The Seventy-first Annual Report of the Council of the Royal Geological Society of Cornwall is issued with part 7, Vol. X. of the Transactions. Amongst the papers there is an interesting description of the raised beaches of Plymouth Hoe, by Mr. R. N. Worth, and an important contribution by Mr. F. W. Millett, on the fossil foraminifera of the St. Erth clay pits. The most noticable feature in this deposit is the complete absence of arenaceous forms of foraminifera; but taken as a whole, such forms as have been recognised indicate a fauna such as might be found in the shallow seas of a subtropical climate. In all probability they belong to the Tertiary period, but that point cannot be settled without further investigation.

Col. Murdoch Smith, R.E., has been appointed director of the Science and Art Museum, Edinburgh.

It is stated that while excavating at the Dumfries Gasworks the workmen came upon a bed of peat in which are imbedded the trunk of a Scotch fir, 6ft. in height, with the bark upon it; pieces of elm, oak, and hazel, with nuts and cones, broken antlers, and various coleopterous remains. In a quantity of the moss placed under glass the cranberry and other plants have begun to germinate after a sleep of centuries. This spot, which is now in the heart of the town, is supposed to have formed part of the bed of a loch in pre-historic times, and three centuries ago a mill-dam was constructed at the place, which was then a morass. The bed of conglomerate on which the peat and other top layers rest has been found to contain large fragments of red granite, a rock which is not known to exist in the immediate vicinity.

At a recent meeting of the Royal United Service Institution, Mr. F. A. Gower delivered a lecture on aërial warfare by means of torpedoes. He proposes to construct aërostats, to fill them from reservoirs of compressed hydrogen, and to send them up when a favourable wind would enable the aëronaut to drop 100lb. shells of guncotton into the midst of an army or into fortified towns.

At the Inventors' Institute last week Mr. Reckenzaun read a paper on "Electrical Tramcars," in which he described a car worked by secondary batteries. For the car there are two motors, each capable of working up to nearly 9-horse power, and weighing 420lb. Each motor is carried separately upon a small bogie, in such a way that each bogie forms a small locomotive engine, upon which the car rests. One axle of each bogie is a driving axle; thus are actuated four small driving wheels. The speed of the motors is high, about 1,000 revolutions per minute when the car is running at seven miles an hour. The gearing employed is a worm on each motor shaft, and worm-wheels on the driving axles, giving a ratio of about 1 to 12. This worm gearing is incased, and the wheels work in oil, the lubrication being perfect. The variation of speed and power is obtained by means of a compound switch, which arranges the motor circuits so that the machines shall work in series, in parallel, or singly; thus the resistance of the circuit being varied, the power and speed vary accordingly. When a greater range of speed is desirable, the motor circuits are still further divided by arranging the field magnet wires apart from the armatures. This obviates cumbersome gearing.

The *Ruapehu*, of the New Zealand Shipping Company's line, has just made the fastest run home on record from New Zealand, having accomplished the distance in 36 days 15 hours. The *Tainui*, of the Shaw-Savill line, left one day before the *Ruapehu*, but was detained 27½ hours longer at Rio, and reached Plymouth two hours after her rival. This is bringing ocean travel to the regularity of the railway.

At the recent meeting of the American National Academy of Sciences, Prof. Rowland stated that the value of the ohm, as corrected by his experiments, came out as equal to 106·2 centimètres of mercury one millimètre square.

The Edison Electric Light Company have commenced several suits in New York against alleged infringers of Edison's patents for incandescent electric lighting. Mr. Edison, it should be stated, claims to be the inventor of the only means for making the incandescent light practical. "Before me, everybody who had experimented in that direction endeavoured to employ conductors of a low resistance. I took exactly the opposite course, working with conductors of high resistance. . . . Subdivision and high resistance are my discoveries, and the great principles upon which my patents are based." Mr. Edison says that the phrase "filament of carbon" was unused until he adopted it, or rather invented it.

M. Fouqué has recently read before the French Academy of Sciences an important paper on the earthquake which occurred in Spain last December. He shows that the epicentre—that is to say, the portion of the surface vertically above the centre of disturbance—was situated between Chorro and Zafarraya, in the Sierra Tejeda. In seeking to determine the depth of the seismic focus, or subterranean centre from which the earthquake shocks were propagated, M. Fouqué rejects the famous method of Mallet, which was applied to the Calabrian earthquake of 1857, and also that of Seebach, applied by Von Lasaulx to the disturbance at Herzogenrath in 1873. In place of these he suggests a new method of extreme simplicity, and requiring for its execution no other instrument than a seconds watch, by which the interval is observed between the subterranean sound and the shock which follows it. In explaining the origin of the Andalusian earthquake, M. Fouqué inclines towards the old volcanic hypothesis, and rejects the supposition that it was connected with any shrinkage consequent on secular cooling of the earth's crust.

THE Natural Gas Company of Bowling Green, Ohio, have struck a wonderful vein of gas in their second well. The pressure of gas threw mud and water out of the well. It is claimed to be the largest flow of gas ever struck, and the amount is estimated at one and a half million feet per day.

**Indelible Stamping Ink.**—For an indelible stamping ink, M. E. Johanson, of St. Petersburg, gives the following for marking textile materials by a stamp: Twenty-two parts of carbonate of soda are dissolved in eighty-five parts of glycerine, and triturated with twenty parts gum arabic; in a small flask are dissolved eleven parts of nitrate of silver in twenty parts of officinal water of ammonia. The two solutions are then mixed and heated to boiling. After the liquid has acquired a dark colour, ten parts Venice turpentine are stirred into it. The quantity of glycerine may be varied to suit the size of the letters. After stamping expose to the sun or apply a hot iron.

**The Largest Steam Engine.**—What is said to be the largest stationary engine in the world is in Lehigh County, Pennsylvania, at the famous zinc works at Friedensville. The engins is known as the President, and as now run, with sixteen boilers, is of 5,000-horse power; with double the number of boilers the capacity of the engine is 10,000 horse power. There is no pumping engine in the world that can be compared with the monster. At every revolution of its ponderous wheels it throws out a little river. The number of gallons of water raised every minute is 17,500; twenty-eight tons of buckwheat coal are consumed by the boilers every day. The driving wheels are thirty-five feet in diameter and weigh forty tons each. The sweep rod is forty feet long, the cylinder 110 inches in diameter, and the pistom rod eighteen inches in diameter, with a ten-foot stroke.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

### ζ HERCULIS—MR. GAUDIBERT'S OBSERVATIONS OF DOUBLE STARS—MR. BURNHAM'S DOUBLE STARS, &c.

[24270.]—THE angle and distance of ζ Herculis in letter 24226, about which "F.R.A.S." inquires in letter 24249, page 256, were given from calculation, not observation. I am surprised at "F.R.A.S.'s" repeated failures to see this object with 4¼in. aperture; but possibly they arise from the reasons set forth on page 157 of the XXXVth volume of the *Memoirs* of the R.A.S., though I should have thought that, with the aperture used, the small star would have been clear of the diffraction ring. The late Mr. Fletcher measured the angle of ζ Herculis on six evenings in 1851, when the *comes* was in exactly the same position as at the present time, with a telescope of precisely the same size as that employed by "F.R.A.S." Dawes saw it clearly divided with his 3·8in. refractor, when the distance was considerably smaller than it is now, and measured it at noonday with 6⅓in.; while I see, on glancing over Vol. XXVI. of the *Notices*, which happens to be bound up with my copy of Vol. XXXV. of the *Memoirs*, that Mr. Burr saw the pair well separated on the 19th of May, 1853, with only 3⅜in. aperture. The distance, according to Dawes, was then 1·66″, and the angle 80·1°. The same position angle will be reached about the spring of 1887. I received a day or two ago the following unpublished measures of this pair in a letter from the distinguished Italian astronomer, Prof. Schiaparelli.

96·05° : 1·515″ : $15^n$ : 1883·57
90·72 : 1·636 : $9^n$ : 1884·58

The results of the separate night's measures of distance in 1884 are as follows:—

1·492″ : 1884·553
1·707 : ·558
1·761 : ·567
1·725 : ·578
1·642 : ·583
1·648 : ·586
1·558 : ·589
1·642 : ·591
1·552 : ·605

The air was not good when the first measure was made. Prof. Schiaparelli has not commenced his measures of this star during the present year as yet, but I have received the following measure on one night from Mr. Tarrant:

90·0° : 1·7″ : 1885·37

This measure is marked "very good." Probably the distance given by me in letter 24226 is slightly too small. Mr. Burnham notes that it was "well seen" with 3¼in. aperture of his 6in. refractor in August, 1879 (Schiaparelli gave 1·380″ for the distance that year from eight nights' observations, and β 1·52″ from three nights), and I just saw it double two years later with 3·2in., and I notice that Mr. Gaudibert split this pair in 1882 with 3½in. side aperture of his 8½in. reflector; and that Mr. Gardiner divided it in June, 1880, with 3¼in. of a 3½in. refractor ("E.M.," Vol. XXXII. p. 378; Vol. XXXV. p. 546). I do not think, therefore, that "Beta" is labouring under any mistake as to his having seen the *comes* with a 4in. Wray this year.

The first portion of Mr. Gaudibert's letter (24224, p. 233) has, I think, already appeared on p. 261 of Vol. XL., and I replied to it on p. 298 of the same volume. I presume that the angle of δ Equulei was about 200° in December last; what is the star S. of it to which he sees a distant *comes?* I think he must be mistaken in the supposed elongation of 85 Pegasi. The *comes* is very small, not brighter than 18 mag. in Herschel's scale according to the mean of 9 estimations by its discoverer (who, with the exception of Prof. Hall with the 26in. at Washington, is the only observer who has measured it), and the distance being less than 0·6″, it could hardly be perceptible as an *elongation* of a sixth-magnitude star with only 8½in. aperture. Moreover, the angle was certainly not 310° at the end of last year. I am surprised that while Mr. Gaudibert appears to see such excessively difficult pairs as 64 Pegasi, 126 Tauri, B.A.C. 6762, β Delphini, δ Equulei, &c., without much trouble, though such objects might be supposed to be theoretically far beyond the grasp of a 8½in. mirror, yet he fails to see such comparatively easy pairs as 7 Tauri, Σ. 3121, and 25 Canum distinctly double. Sch. found 25·8°: 0·45″ for Σ. 3121 in 1882·31, the stars being in contact or divided at times with the 8 6in. refractor, power 690; the angle should now be about 35°, and the distance 0·55″. Of 25 Can. Ven. Schiaparelli writes:—"Questa stella, esaminata da me più volte nel 1875, mi era sembrata semplice. Soltanto il 5 Giugno 1876 vidi il satellite uscire fuori dalla luce della stella principale, da cui posteriormente si venne poco a poco allontanando." Ds. found 151·77° : 0·748″ : $4^n$ : 1878·41; Sch. 151·28° : 0·70″ : $8^n$ : 1882·45, the stars being "ben separate" in only moderate air in 1881 and the following year. The angle should now be about 148°, and the distance is not under 0·70″. Mr. Perry's distances are frequently much too small; but Mr. Gaudibert has overlooked Mr. Perry's measure (0·6″) in 1883·42. The angle of 42 Comæ can never be 130°; it is now about 5°, and the distance is certainly under 0·25″. The angle of 32 Orionis is probably nearer 195° than 165°, that which Mr. Gaudibert gives for ω Leonis is about correct; the position and distance calculated from Do.'s first elements are 93·5° : 0·66″; but this angle is probably too small, and the true one is nearer 103°. I do not know the quoted measures of 64 Pegasi in 1880; Mr. Burnham's measures of O.Σ. 234 are the latest I have seen. De. found only a doubtful elongation on two nights in the spring of 1877 in 139° and 116°; while Sch. found it single many times in 1875 and 1877. He suspected a prolongation of the disc in the direction of 133° on April 26th, 1879; but he writes that the observation was a *very* doubtful one.

A careful examination of the following pairs during this or next year would at once show whether they are physically or only optically double. Ceti 82 (β 395), ω Andromedæ (β 999), B.A.C. 525 (β 870), 58 Ceti (β 7), 48 Cassiopeiæ (β 513), 66 Arietis (β 878), $p^3$ 65 Leonis (β 599), 46 Virginis (A. G. C. 5); 48 Virginis (β 929), B.A.C. 3992 (β 603), Corvi 26 (Hvd. 131 = β 605), 6 Serpentis (β 32), 90 Herculis (β 130), B.A.C. 6480 (β 648), 14 Aquarii (De.), 34 Pegasi (β 290), 78 Pegasi (A.G.C. 14), 27 Piscium (β 730). I should be glad to know whether Mr. Gaudibert noted the angle of B.A.C. 3992 (β 603), when he examined that pair last year. β gives for this 7·0, 11·0; 337·7° : 1·52″ : 1878·2, and it seemed unchanged in 1880. I find with the p.m. which I have adopted that the angle should have been 22·5°, and the distance 1·73″ at the date of Mr. G.'s observation, if the stars were *not* physically connected. He mentions in letter 22820 in the "E. M." for June 6th, 1884, that he saw the *comes* separated from the large star"; but he does not give any estimate of the angle.

I would draw particular attention to the close pair, Ceti 82 (β 395). In the case of this star the p.m. is no less than 1·355″ annually, about the same as that of 85 Pegasi; and as the pair was discovered by β on November 5th, 1875, the change should be very evident if the stars were not physically related. I have no doubt about their connection, however, as the pair would otherwise have been seen widely separated by Piazzi and Taylor. β estimated P. = 135°, D. = 0·5″, mags. 6·0, 6·0 at the time of discovery; but I am not aware that it has ever been measured. It is perfectly visible to the unaided eye, and its place for 1885·0 is 0h. 31m. 26s. South Decl. 25° 24·0′. 9 Argûs (β 101) is another close pair with considerable proper motion (0·37″ annually); but here the binarity has also been shown from the measures. The proper motions of β 999 and 599 are about the same as that of β 101, and those of β 290 and 648 rather less.

"Garrison Gunner's" letter (24225, p. 233) admirably explains Mr. Nelson's difficulty. It would be interesting to learn with what apertures Mr. Nelson can see the following pairs: ξ Boötis (Σ. 1888), δ Serpentis, α Herculis, μ Draconis, λ, τ, and 70 Ophiuchi. During the transit of Venus in 1874, the planet, which subtended an angle of about 64·0″, was distinctly seen by some observers on the sun's disc with the naked eye. I may remark that Dawes sometimes divided pairs at a distance considerably closer than that indicated by his own formula—*e g.*, he saw η Coronæ completely divided with his 3⅞in. Dollond in May, 1831, the distance then being only 0 88″.

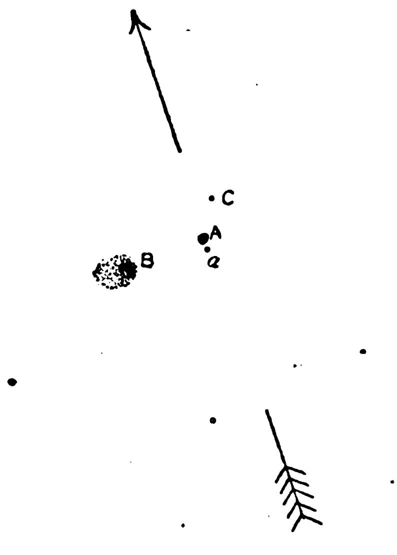
May 22nd. **H. Sadler.**

P.S.—Dr. Eugelmann gives the following measures of 25 Can. Ven. with the 8in. Alvan Clark, at Leipsic:—

149·30° : 0·748″ : 5 – $4^n$ : 1882·33
151·37° : 0·802″ : $6^n$ : 1883 43

### H (G C) 2091. (H 2529).

[24271.]—I SEND a rough sketch of this interesting object, which, thanks to a tracing from *Peters'* Chart most kindly supplied by Mr. Sadler, was found without difficulty on the night of April the 15th, and has been systematically observed since. The weather of late has been most unfavourable for delicate work, only three nights—viz., 21st April and 1st and 2nd May yielding any really satisfactory results. With regard to the close pair, A *a*, I have never been able to obtain any definite evidence of its duplicity, partly from want of light, and also that it is a most difficult object to focus; still, there has always been a peculiar appearance about it, *p.* and *f.*, and I have little doubt a larger aperture would show the P.A. of the small star to be about 90°. The star B is very nebulous; in fact, immersed in the S. edge of the nebula, giving it the appearance on some occasions of a telescopic comet. On this account any estimate of its magnitude must be most uncertain. The star C, although noted as "excessively faint" by Burnham with the 18½in. at Chicago in 1879, was most obvious on the 21st April and 2nd May, and was estimated at about 12 of Σ.'s scale; the P.A. from A 235° ± dist. 9″ ±. The nebula itself bears magnifying fairly well, and has been well seen in strong moonlight; it seems elliptical, the direction of the longest diameter being N. and S., and is now quite 20″ from the close pair, at 360°. There seems little reason to doubt very considerable proper motion in distance on the part of this nebula, for, by comparison of the data given by Mr. Sadler (letter 23999), we find that when discovered by H in 1830 the pair A *a* formed the nucleus of the nebula; the Parsonstown observation in 1851 seems to show that the nebula was then midway between A and B. In 1865 the star B formed the nucleus, and it now is quite at the S. edge, if not altogether clear of it. The outlying stars, several of which are in the field with a moderately low power would afford an excellent means of measuring the motion micrometrically, as the angle seems unaltered. The full aperture of my 10¼in. Calver has been used; powers 60 to 320. Allow me to thank Mr. Gaudibert for his interesting letter, but I would point out that the elements of 42 Comæ give for this year P.A. 5°, dist. 0·13″. I have obtained a doubtful elongation with 850 on one occasion, but it, like 8 Sextantis, is generally far beyond the reach of my instrument, fine mirror though it is.



**Kenneth J. Tarrant.**
Letchford House, Pinner, May 15.

### THE SEPARATION OF DOUBLE STARS.

[24272.]—MANY thanks to "A Fellow of the Royal Astronomical Society" for his reply, and for the table of measurements of star discs. From it I conclude that the diameter of a star disc varies directly as the aperture, the power being constant. I presume that those measurements were made with the same object-glass stopped down. Would "F.R.A.S." kindly say if a different result would have been obtained if object-glasses of various focal lengths had been used; also, if the passage, "press deep eyepiecing as we may, we shall always have our stars in contact," means that the aperture being constant, the diameter of the star discs varies directly as the power? I mention this because I have been under the impression, owing to my limited experience (288 on a 4in. being my highest power), that star discs were amplified in a ratio wholly incommensurate with the increase of magnifying power. The impression has been strengthened by Sir W. Herschel's measurement of α Lyræ—viz., 7ft. Newtonian, 6¼ ap., power 460. ⅒in. diam.; power 2,010, ⅛in. diam.

There is a seeming contradiction here. Is it caused by the different performance of reflectors and refractors, an error on H.'s part from want of instruments of precision for measuring, or what?

This morning I was truly grieved to learn, from the obituary notice in the *Times*, the loss we have all sustained by the death of the Rev. T. W. Webb. Though most of us were probably unacquainted with him, even by sight, I am sure we shall all miss him as a personal friend, so well did we know him by his work.

May 25th. **Edward M. Nelson.**

## ASTRONOMICAL.

[24273.]—You will remember that I announced the discovery last year of two new *comites* to 39 Draconis. I beg to announce the discovery on April 23rd of a third *comes* still nearer to the primary. This one is about 35″ distant and 260° or 270°. It is thus less than half as distant as the old well-known *comes*. It seems remarkable this star should have escaped notice so long, as it was visible in moonlight both on the 23rd and 24th with 9in. mirror. **Edwin Holmes.**

## ORIGIN OF COMETS.

[24274.]—In your summary of the proceedings of the Liverpool Astronomical Society, Mr. Denning is represented as giving reasons why a cloud of meteors ejected from a planet, so as to move in a cometic orbit round the sun, might ultimately be expected to form a ring of meteors. No possible objection can be raised to Mr. Denning's argument so far; but whether the total mass of meteors, say, in Tempel's meteor-comet, might not be so great as to render its planetary origin improbable, as Mr. Sutton supposes, it is not easy to say.

But I fail to understand why any comets, or comet-systems, are supposed to arise from planetary eruptions. It is impossible, of course, to prove the negative; but I presume the only reason for such an assumption is the close contiguity of many cometic orbits at some points to those of the planets.

Now, it can easily be shown that if a comet move in an orbit whose aphelion distance is greater than the distance of Neptune from the sun, such an orbit, owing to its perihelion and node-movement, more particularly the latter, will sooner or later come successively into a position of contiguity with all the planetary orbits, and will remain a considerable time in such a position, above all when the planet is Jupiter. Taking this latter circumstance into account, the orbit of any comet taken at random, with a sufficiently large aphelion distance, would very probably be found to be either contiguous to Jupiter's, or that of one of the superior planets.

I have, however, omitted to consider what may be considered by some as the strongest argument in favour of the planetary origin of most of the comets. That is, that all the comets that do not proceed into unknown regions, with the sole exception of Denning's comet, have their aphelion distance nearly equal to the distances from the sun of the four major planets; but if we suppose eruptive discharges with a sufficient velocity to proceed from a planet in all directions, but a very small percentage of the cometary orbits supposed to arise therefrom would fulfil the above-mentioned condition of the aphelion distances, and we should expect that such cases as Denning's comet would be the rule, and not the exception.

Whence we must conclude that the law of aphelion distances has some other cause than the origin of comets from planetary eruption.

**W. C. B.**

## THE ECLIPSE OF THE MOON, MARCH 3, 1885.

[24275.]—The moon had already risen nearly 6° above horizon, when an opportunity was offered me to go to my observatory. Detached clouds floated about, and much interfered with observation. On turning the telescope on the moon, the bluish twilight was readily seen extending some distance round the dark limb each side of the light cusps.

The dark shadow was just outside of Plato, and rendered the interior of this ring plain, of a dark colour, contrasting strangely with the surrounding bright regions.

The highlands, or hill country, bordering the Mares, and just inside the dark shadow, were of a light bluish green, while the Mares remained dark right up to their boundaries. About ten minutes later on this illumination of the highlands, especially southward of the Mares Crisium, Serenitatis, and Iridium, and the long neck of highlands stretching down on to Herodotus and Aristarchus, seemed to become much more brilliant, and formed a considerably wide belt all along the shadow. This contrasted very strangely with the darker Mares, as these plains did not seem to be similarly affected. Nor did this illumination last long; in about five minutes it had decidedly become less bright. Aristarchus and Herodotus were very conspicuous, while yet the dark shadow lay close to Plato.

The preceding half of the plain, inside of Plato, was very noticeably darker than the following. The latter half had a stifled appearance. When the shadow line had reached to midway between Plato and Aristarchus, I could plainly trace the limbs of the obscured part all round.

Finally, the shadow left the edge of the moon in the Mare Australe, somewhere behind Mounts Oken or Vega.

The broad greenish-blue band bordering the shadow, and only seen on the highlands of the moon, seems to me worthy of notice. Is it the more varied angular inclination of the surface which thus causes a greater amount of reflection of earth-light received *through* the ring of our atmosphere? Or have the constituents of our atmosphere to account for part of the colour?—while the greater slopes and varied surfaces of the moon's hilly regions collected more of this light and colour to return to us. **John Ballot.**

Rolfontein, Transvaal, S. Africa.

## ζ HERCULIS.

[24276.]—I am exceedingly obliged to Mr. Sadler for the kind trouble he has taken in examining the above star for me, and gratified to find that my conviction is correct as to the distance between its components, being at present greater than any quoted in Webb.

Bearing in mind the suggestions of "F.R.A.S." as to diffraction rings, and even as to having mistaken the star, I examined it carefully this evening, definition being excellent, and unquestionably saw it distinctly double for the third time, both with 255 and 400. Of course, I do not mean that I clearly *separated* it; but that it was sufficiently divided to render its duplicity a matter of certainty and instant remark. The position of the *comes* exactly corresponds with the angle given by Mr. Sadler.

How it is that "F.R.A.S." cannot see it otherwise than as a single star, I fail to understand; his o.g., however, is probably no larger than mine; for although I called my telescope a 4in. for brevity, it has a *clear aperture* of that diameter, and the o.g. must, therefore, be about 4⅛in.

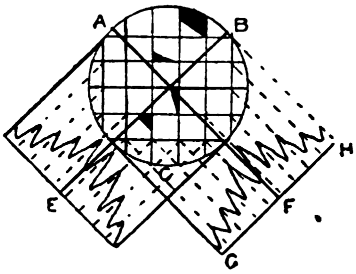
London, May 23. **Beta.**

## GRINDING AND POLISHING GLASS SPECULA.

[24277.]—I think now is the best place to introduce the amateur to the study of the side motion, as it will be fresh in his mind what I taught him in my last letter—that the parts of most resistance, and therefore most cut, are the centres of the facets; therefore we have to do with parts that cut much and with other parts that cut but little, and also the grooves, where there is no cut: it follows that at each straight stroke only parts of the face of the speculum are being worn, and these practically straight lines; but by the revolution of the speculum, combined with the revolution of the polisher, these lines are crossed over one another, so that all parts of the speculum are equally worn. Now, let the amateur suppose one set of grooves of the polisher to be parallel to the straight stroke during that straight stroke. Of course the grooves not cutting would leave the face of the speculum where they passed over elevated, while where the lines of facets passed over would be worn into grooves on the face of the speculum, the lowest parts being where the line of the centres of the facets passed over. All this would be true from side to side of the speculum. Now, let the amateur suppose the polisher turned round one quarter of a revolution: we now get another set of grooves and lines of centres of facets brought into action, but not in the same places as the former ones, thus tending to equalise the action of the cutting surfaces from side to side of the speculum. Now, let the amateur again suppose the polisher turned round one quarter of a revolution: he will now have the first set of grooves and lines of facets brought into use again, under the same conditions as at the first, except that they are not over the same places on the speculum as either the first or second cases; again, let the amateur suppose the polisher turned round one quarter more, when the same grooves and lines of facets will be brought into action as in the second supposed case, but not in the same places as in the first, second, or third cases, so that the inequality of cut caused by the grooving is reduced to one quarter by the arrangement of the grooves I have explained in a former letter. So far for when each set of grooves is parallel to the straight stroke; but we must take into account when the grooves are at an angle of 45° to the straight stroke, and as there are four places where this can occur, we shall have, with the four places where the grooves are parallel to the straight stroke, studied the action of the polisher over eight of its diameters, which is certainly for all practical purposes pushing our researches far enough. I give the reasoning on these points, so that anyone coming after me in this study may have the advantage of knowing how far others have gone, and the laws that have already been discovered, and thus start in their researches from where others have left off. I will give also the practical directions so that any amateur who wants simply to work a speculum may do so at once, so as to conform to the laws I explain without the necessity of mastering them, though this latter I strongly advise. We will now examine the lines of most and least cut when the grooves are at an angle of 45° to the straight stroke.

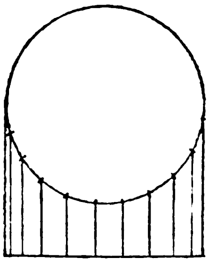
Fig. 1 represents all these four conditions of the straight stroke, A B C is the polisher with lines to represent the place of the grooves; no great accuracy of representation is aimed at, as my object is only to describe the principles brought into play. I suppose (though not represented) the facets are graduated so as to produce the parabola, as I have fully described in my former letters, but not obliterated. Now let the line A F represent the direction of the straight stroke along which the polisher is moved; if parallel lines were ruled to this (I rule them ⅛in. apart) and the length of cut measured upon these from the base line G H, it would be found that the cut would be represented by the zig-zag line from G to H. Now it will be observed that the hill of most cut to the right of the diameter line A F, is ¼ the distance from this diameter line, that is between the centre of one hill to the centre of the next hill, so that when the polisher has revolved half-way round, the centre of the one hill of most cut would be put over the centre of the valley of least cut, and so with all the other hills and valleys; thus this whole set of hills and valleys will be practically obliterated. Now let us take the other diagonal straight strokes represented by the diameter line B E. Here it will be seen that the hills or lines of most cut, on both sides of the centre line, occur at equal distances from that line, and therefore the effect of these hills or lines of most cut, on one side of the diameter line, will be when the polisher has turned half-way round, to increase the effect of the hills or lines of most cut on the other side, and thus to produce rings of hollows on the face of the speculum corresponding to the distances the hills or lines of most cut are apart. Now, it is interesting to discover that these hills occur exactly at the same distance from the centre line B E, as the very faint rings for which I have directed the amateur to make certain obliterations in the facets in parts where these rings occur (see Vol. XL. p. 322). So that out of the eight diameters that we have divided the polisher into to study the effects of the grooving and straight strokes, it is the straight strokes that are parallel to the diameter line B E, of the graduated but not obliterated polisher that produce the last crop of faint rings, the cure of which is the obliterations. I have marked where they occur in black on Fig. 1.

FIG. 1



Now, it might be naturally asked if the above polisher with properly graduated and obliterated facets will produce the parabola without rings, what use is there in the side motion, for it seems to have come into use because it removes many irregularities, and further, it is evident that the only place where one parabola can fit on another is where they are central to one another. Now the polisher by the side motion is kept much off this central point by the straight stroke being carried from side to side. And with a circular wheel on the side motion axis, the straight strokes over the centre of the speculum are only about one quarter those on either side, but more of this further on. Now, these conditions led me to abandon the side motion at one time, for I have with care easily produced the regular parabola without it, but with all my care I found occasionally rings would occur from accidental causes. Thus, perhaps, some of the facets would alter during a night from the general level, and after the first half-hour's polishing in the morning, I should find upon testing that I had very faint rings, and that it would take the whole of the day of six or eight half-hours' polishing to get these rings out, they only very slowly disappearing without the side motion, for I found that the speculum with rings had the power to form a polisher with rings, and the polisher and speculum acted and reacted on one another, so that the rings were perpetuated for a long time, and while the tendency of the polisher properly faceted and obliterated was to gradually remove the rings, it took sometimes seven or eight half-hours'. polishing to remove a crop of accidental rings, while if I applied the side motion, they were nearly removed in one half-hour's polishing, and completely removed by the end of the second half-hour's polishing; or by displacing the faceplate on which the speculum was fixed to such a distance on one side as to throw the hills into the hollows in one complete revolution of the speculum, I could get rid of the rings. But I must explain that one amount of side motion or displacement of faceplate only suited one width of hollow or hill, so that the side motion or displacement of faceplate is not perfectly effective when there are different widths of rings on the same speculum. Now, speaking generally, the tendencies to rings of elevation and depression were blended together into one general level surface on the speculum, which, acting on the polisher, produced a generally level surface on it, which generally level surface had no tendency to produce rings, provided it was properly obliterated. Now, as I have before stated, these accidental rings only very occasionally occurred to me; but I thought, to the amateur who has not had the experience I have, they would certainly occur much more frequently, and therefore it will be safer for him to be recommended to use the side motion; and so I have described it in its simplest form—viz., with a circular wheel to produce it. But we are now in a position to study the side motion more fully, and to find out the best form and quantity of side motion. The amateur will easily understand that with a circular wheel to produce the side motion, the polisher will be kept more at the extremes of the side motion than at the middle. This I illustrate in Fig. 2, where I suppose there are twenty-two straight strokes to one revolution of the side motion wheel. I have only traced the straight strokes for half the revolution, because, of course, the other half would only be a repetition of that shown. It will be seen that the straight strokes are much closer together towards the extremes right and left, about one-quarter as far apart as those over the middle. Therefore, there will be about four times as many straight strokes in the worst position as there are in the best position or over the centre of the speculum. Now, to correct this, I use an oval side motion wheel instead of the circular wheel O, shown in Fig. 3, p. 113, Vol. XXXVI. This oval wheel is driven by the circular small wheel M by means of a guttapercha round band or gut. The long diameter of the oval is seven times the short diameter. This I find produces an equal rate of side motion from side to side. The proportion 7 to 1 refers to the bottom of the groove round the oval wheel, which groove is very deep, about ¾in., the gut is about $\frac{3}{16}$in. diameter, the wheel M is, in diameter, a mean of the larger and smaller diamers of the oval wheel; actually my oval wheel is 7in. long and 1in. broad (at the bottom of the groove), the wheel M is 4in. diameter. This arrangement causes the motion to be equal from side to side, and not as shown in Fig. 2, *i.e.*, it causes the straight strokes to be as numerous over the centre of the speculum as at the extremes of the side motion. I give a drawing of the oval wheel arrangement in Figs. 3 and 4. In Fig. 3 the oval wheel is shown in the position, when the straight stroke is over the centre of the speculum, it will be there seen that, as the longer diameter of the oval wheel is in action, the side motion will be caused to be slower while passing over the centre of the speculum, while in Fig. 4 the shorter diameter of the oval wheel being in action, the side motion will be greatly accelerated, while, at the extreme of each side, by these two actions the unequal rate of the circular wheel side motion is reduced to an equal rate from side to side. This oval-wheel arrangement takes more room than the circular-wheel arrangement, because the distances between the wheel M and the oval wheel O has to be more, to allow the gut to be nearer parallel, and thus not slack and tight alternately as when these wheels are closer together, and, again, the oval wheel itself takes more room than the circular wheel it is substituted for, therefore the machine will not take in a 12in. speculum; but this is remedied by simply making the foundation plank 8in. longer—viz., 3ft. 8in., and then putting the upright shaft on which the oval wheel revolves 3in. further from the faceplate axis, and putting the wheel M 5in. further from the oval wheel axis.

FIG 2



Having now decided which is the best form of side motion, we have to decide what is the proper theoretical amount of side motion. I say theoretical because with a properly grooved and graduated and obliterated polisher there is no tendency to produce rings; therefore any amount of side motion that is not excessive may be used; but it will be well to understand what theoretically is the proper side motion, and upon what laws its use depends. I may just observe in passing that, for a 6in. speculum and 1in. between the grooves of the polisher, and the circular wheel side motion, I have ascertained both practically and theoretically that ¾in. is the best amount of side motion, and very good work can be done with this, but I shall not explain the theoretical part of the circular wheel side motion, because the oval wheel is in every way superior, except that it is a little more difficult to make. Now a very different and a very much simpler set of laws govern the oval wheel side motion. Now to study these laws let us put ourselves in the very best position to produce rings, and then by the regular side motion let us obliterate these rings; this in passing, I may just observe, cannot be done by the irregular (*i.e.*, the circular wheel) side motion, under the unfavourable circumstances I am about to suppose. I, therefore, strongly recommend the adoption of the regular (oval wheel) side motion for all sizes of specula above 7in. diameter. Now let us suppose we are working with a polisher that has its middle groove right across its centre, and that the next grooves on either side are 1in. from the centre, and the next 1in. further, and so on to the outside, and further let us suppose the polisher is kept from revolving, and that one set of grooves are parallel to the straight stroke, and, lastly, that no side motion is used, but that the centre of the polisher passes over the centre of the speculum at each straight stroke. Now it will be evident to the amateur at once, who has read my previous letter attentively, that the centre of the speculum will get no wear, and therefore a central mound will be left, and further that at 1in. on either side a ring mound will be left as the speculum revolves, and another ring mound outside this 1in. from it, and thus on to the edge; in other words, there will be annular mounds corresponding to the position of the grooves on the polisher, and annular valleys corresponding to the position of the lines of facets. Now let us suppose a small amount of regular side motion put on, say ¼in.; this small amount would be an advantage, for it would broaden out the valleys, and thus reduce the hills, but it would not obliterate them. To illustrate this, let the top wave-line of Fig. 5 represent two adjacent hills or mounds on the speculum over which the grooves happen to come, with the hollow A produced by a row of facets; we will consider the effect of a point A in a facet. Of course the same reasoning will apply to all other points; and now let us suppose a regular side motion of ¼in. In this case the point A will be carried regularly ¼in. on either side—*i.e.*, from A to B and from A to C (see the second wave line). Now let this wave line be carried from A to B and from A to C, which I have represented by the dotted wave lines. Now the point A being carried regularly over the space from B to C, while the straight stroke carries it backwards and forwards, it will, of course, regularly wear this space, but will leave the spaces from C to D and from B to E untouched; therefore there will be still left the mounds represented by the dark parts on C D and B E, smaller than the original mounds. Now let us suppose a ½in. regular side motion, this is represented by the third wave line, where the point A is carried regularly ½in. on either side of A to B and C, leaving the spaces C D and B E untouched. Now here the remaining mounds over these spaces are seen to be much smaller than for a ¼in. side motion, while in the fourth wave line, which is to represent a ¾in. regular side motion, the mounds on C D and B E are seen to be very much reduced; the last wave line represents a 1in. side motion, that is, the same as the width of the grooves apart, where it will be seen the points C D coalesce, as also do the points B E, thus obliterating the previous mounds; in other words, the point A (and this is true of all other points) is carried regularly over the face of the speculum to the places where the corresponding points in the adjoining facets on either side are also carried, and if we study them in like manner we shall find that they, and all other points, would have their effect equally distributed over the face of the speculum from facet to facet, proving that the proper amount of side motion is the distance any particular point in a facet, say its centre, is from the corresponding point or centre of the next facet, or a multiple of this distance. The above rule applies to the four diameters parallel to the grooves; but in Fig. 1 of this letter I have represented the wave line produced by the more and less cut of the four diagonal diameters, and these waves are not 1in. apart, but about ·7in., therefore the regular side motion for these ought to be ·7in., or multiple of this, and by finding those multiples that nearest approach to multiples of 1in. we could choose the very best reguler side motions, and if we could not find among these multiples a quantity we wanted for any particular sized speculum, we could make our grooves wider apart, say 1¼in., or 1½in., or 1¾in., when we should get a fresh set of multiples to choose from, *i.e.*, if we wished to be theoretically correct in our regular side motion. The above reasoning applies to a polisher in the very worst conditions, and yet with these unfavourable conditions, with a properly calculated regular side motion, a speculum free from rings may be produced, but not with an irregular, *i.e.*, circular wheel side motion can this be accomplished; and I give the above explanations to show the amateur the superiority of the regular side motion. But I must futher explain to the amateur that, with a properly grooved polisher and proper obliteration, the causes of rings at their sources are removed (and this we should always aim at), and therefore any particular quantity of regular side motion may be used, its use being reduced to the prevention of the perpetuation of accidental rings, and for this I find from the ⅙ to the ⅛ of the diameter of the speculum is enough, and this is all the amateur need attend to if he be careful to have a properly formed polisher, combined with a regular side motion, one of the great advantages of the latter being that it keeps the polisher longer over the centre of the speculum than the irregular, *i.e.*, circular wheel side motion does, and this I have proved practically, as well as theoretically, to be an important element of regularity of figure.

W. A. Wassell.

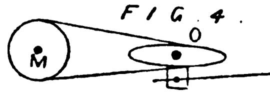

FIG 5.

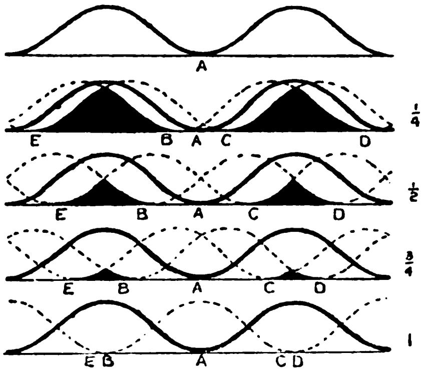


## CURVES FOR SPECULA—TO MATHEMATICIANS.

[24278.]—If the great mirror is a parabola the convex mirror of the Cassegrain should be an hyperbola, and the concave of a Gregorian should be an ellipse. So much for (well known) theory, but in practice the small mirror is worked to a spherical curve, and the curve of the great requires modification.

In testing mirrors by the method used, and so clearly described, by Mr. Wassell, the aberration of the parabola at centre of curvature is calculated, and the actual aberration compared with it.

Is it not possible to calculate what should be the aberration of the great mirror of a Gregorian or Cassegrain when similarly tested, so that it should work with the spherical small mirror?

At present a tedious process of trial and error has to be gone through till an approximately correct result is obtained, more by chance than by knowledge.

Dr. Royston-Pigott's articles on the Cassegrain (unfortunately suspended when incomplete) have recalled attention to this question, which is surely within the grasp of some of our mathematical friends.

A. S. L.

## EVOLUTION.

[24279.]—"Pre-Adamite" says:—"Surely if a fish's surroundings were changed, the fish would die instead of accommodating itself to them?" First, it depends on the extent of change. Second, does "P." think to reduce evolution to the life of "a fish?" I thought in my last I had at least shown him that the "change" which takes place in the creature is not confined to an individual but many generations, and that this change is chiefly that of difference between parents and children. "P." will be disappointed if he thinks that *he* can bring about *any amount* of evolution *in any direction* during his lifetime ("the drying up of a pond"), or that of a fish! Does he really think that a man could dry up a pond of sticklebacks and leave it, when he dies, a patch of dry ground and the sticklebacks metamorphosed into lizards? And if he extends the drying up (though why he should think that simple drying up of the pond—taking away of the very life-element—should be the means of evolution, I don't know) over many generations, I should like to ask him how he knows that Nature does "yield up the struggle," as he cannot see both ends of the process. With regard to the evolution of the seal, I don't think it is known in what direction it is tending; but, of course, it may be in either direction, or neither, or both (*i.e.*, some tribes may be becoming more aquatic, others the reverse). In saying fish were the ancestors of mammals, I spoke generally, meaning that fish existed on the earth before mammals. Of course, mammals may, in some cases, be changing and becoming aquatic, and may have done so before now.

I think if "P." studies the "chain" of existing and fossil creatures known, he will find that there are no very great gaps; some gaps must be greater than others, but I don't think that is any reason for rejecting the theory for them, even if they are inexplicable from an anatomical point of view.

If three different forms were specially created (fish, bird, and mammal), why do those three forms run as much into each other as they do? I think it more likely that they would be *totally* different. I think you must either wholly accept or wholly reject evolution (and you cannot very well do the latter). If you strike a medium which seems to me very unreasonable and unnecessary, you cannot tell where to draw the line, as far as I can see (not at gills, I think), and you embrace the difficulties of both theories while you lose the advantages, so to speak, of the theory of evolution.

Those who take a medium theory must settle "P.'s" question about the "half-lizard and half-fish" among themselves, for the question has meaning for them only, and it matters little what the answer be, as long as it satisfies them.

But I don't think they *will* find an answer, and I think that the more "Pre-Adamite" studies evolution the more he will be inclined to accept it. I do not think, with "H. B. F.," that this controversy leaves all, if any, of the disputants where it finds them. **Crumby.**

## EVOLUTION.

[24280.]—IF the theory of evolution has any truth, *life* must have been a process of evolution. May I ask some who know so well, what were the conditions of habit, custom, or necessity which produced that evolution? Why was the inert atom of calcium, or the floating bubble of oxygen, compelled to other conditions than those in which they were?

Spontaneous generation, the prime apostles of evolution themselves declare an impossibility. How was the first life evolved? Again, how were the *first organs of reproduction perfected* for their first use? By what habit, custom, or necessity did the first life (Mr. Darwin's "protoplasm") evolve *a prescience of its future* requirements, what need even for sexual arrangements? Evolution of life from elements is certainly more simple than reproduction by complex processes. Fifty other such questions must be answered before a pebble to stand on can be found as a *foundation* to the scheme; even Mr. Darwin, with his great ability, and with his extraordinary honesty, commences his admittedly great work in the middle of the subject.

The truth is, this theory of evolution is thoroughly unscientific; it is a scheme of suppositions, to explain facts by a novel method. Many of its evidences are begged, and much of its argument about rudimentary organs has been amputated by physiologists at least as thoughtful as any of its supporters.

In this strong point of rudimentary organs we have plenty of evidence. How readily we see what we wish in the random assertions of many who should know better, such as the rudimentary tail, and the gill slits in the human embryo, and the "young whale's teeth"!

There is just as much evidence that "rudimentary" organs are, as the term properly implies, in process of *perfecting*, as in process of degrading, and that is no *real evidence* either way.

I fear the disciples of the theory mistake the marvellous *unity* of an undoubtedly direct creation, distinctly exemplified in all the obvious *facts* around us, by which facts I am told the most distant star my telescope reveals to me is of the same elements as the bodily structure my soul inhabits, as the rock on which I stand, as the water with which I quench my thirst.

The speciousness of the theory had for some time a strong influence on myself, but having read all the best writers for and against; unless I can get some common-sense answers to such questions as I have asked, shall now sign myself

**A Convert from the Theory of Evolution.**

[24281.]—As to the point raised by "W. G. P.," there may be sometimes, although I think but rarely, a difficulty in deciding whether a structure now apparently without use, was once effective, or whether after certain changes it is about to become so.

The swim-bladder of fishes is perhaps a case in point. We have at present fishes without any, also bladders without any outlet, as well as those opening into the esophagus, but non-cellulated, and others also with an opening, but cellulated, acting as rudimentary lungs.

The received opinion is, I believe, that all these proceed from a non-cellular bladder with an outlet acting functionally, in the first instance merely as a swim-bladder which has developed in two directions. But the non-cellular swim-bladder, even in its best form, appears to me as most probably an abortive organ whose first function was to aërate the blood, and its first form a vascular indentation of the anterior portion of the esophagus.

I am inclined to think that the wholly inclosed swim-bladder is upon the whole a decided disadvantage to the animal possessing it.

The whole course of the embryological development of the higher animals is a continued development of organs which become aborted. Take in man the aortic arches, same in number with those of fishes, and which afterwards are almost entirely obliterated, and out of the scraps left our more simple system is formed in a somewhat awkward manner. In fact, however we may admire in many respects the operations of nature in the formation of organisms, she cannot be congratulated upon doing her work in the shortest possible manner, or upon not frequently using the feminine privilege of changing her mind.

We may conceive something like such a style of workmanship if we suppose a manufacturer of chairs, tables, and ladders always beginning with chairs; then, if tables are required, destroying some of the chair and making additions to form the table, leaving portions of the chair legs sticking out from the surface. Then, again, if ladders are wanted, the chair as usual is begun with, then obliterations and additions till a table is almost formed; and then more obliterations and alterations until finally a ladder is arrived at, in which, however, the remains of the chairs and tables can be detected impairing the utility of the ladder.

**W. C. E.**

[24282.]—IN letter 24256 "H. B. F." gives us a definition of evolution and creation. I should like to ask him how can any man know that a "quality" is not previously existent even in a latent state? Again, he says, "It cannot be admitted that the simplest organic form could possibly have held latent within it the diversified organic characteristics," &c. I should like "H. B. F." to study "embryology." Why, there we have "evolving" from an infinitely small speck of protoplasmic matter within the short space of 20 years a perfect adult man. Or is "creation" constantly at work producing fresh "special," previously non-existing qualities, in each individual man? The same everywhere in the works of Nature: from the "seed" springs in time the mighty oak, &c.

I sincerely believed "creation" simple—*i.e.*, something out of nothing, was at this time of day gone with other ancient ideas, such as mythology records among all nations, from Minerva springing fully armed out of the head of Zeus, down to the "perfect man created" on the sixth day of this planet's existence.

The thing is irreconcilable. If "creation out of nothing" is reasonable, Evolution must go. The same *vice versâ*. **F. W. H.**

## WHEATSTONE'S BRIDGE.

[24283.]—HAVING had some experience with the bridge, I can give a few hints as to the use of it.

The bridge described by Mr. Bottone, though very useful for measuring low resistances, is not suitable for measuring high ones. Even if it were, a resistance of some hundred ohms, measured as described from a 1 ohm coil as a basis, would be inaccurate. I have a bridge with a thick and thin wire, either of which can be used at will. The range of the bridge is thus much increased.

The following are useful tests to ascertain whether the bridge is in good order. To test the sensitiveness of the arrangement, shift the key after balance has been obtained. A very small movement of the key should affect the galvanometer. To test the accuracy of the bridge, balance the standard and tested ohms, then reverse their positions. On again pressing the key, there should be no motion of the galvanometer needle, if there is, the bridge is faulty. The fault lies either in the stretched wire, which is uneven, or in the connections. The wires and terminals should be clean and in good contact with the copper strips. The stretched wire should be soldered to the copper strips. Dirty and insufficient connections are the chief sources of error in measuring small resistances.

A low resistance battery is best. I prefer a bichromate, with lifting arrangement for the plates. A constant battery is unnecessary, as only momentary currents are used.

I will next week give directions for making a sensitive astatic galvanometer. I shall be glad to show a bridge at work during the first four days of the week to anyone who may care to call on me.

97, Crawford-street, W. **G. Bouron.**

## AGAIN DISAPPOINTED.

[24284.]—I AM sorry to trouble you again; but I wrote once more, inclosing cash, and using the number "Montmartre" kindly gave in letter 24217. The result was receiving back my P.O O. and the inclosed letter, stating that the "tickets of the Society are not transferable, and that the orders should emanate from the members themselves." I am again much disappointed.

9, India-street, Edinburgh. **G. Dickson.**

[It is a pity that red tape has again defeated "Montmartre's" kind intentions. Can he not arrange with some respectable optician to supply, and not trouble the Stores?—ED.]

## HIGH POWERS IN OPERA-GLASSES.

[24285.]—"MONTMARTRE'S" letters about opera-glasses seem to be developing into advertisements in favour of a certain co-operative store. His notions on the subject are at the least peculiar, and liable to mislead. Very high power in an opera-glass can be obtained only by sacrificing light and field to such an extent as to render the instrument (in the opinion of most persons) totally unfit for use as an opera-glass. No wonder that "Montmartre" tried in vain to find such a thing in the shops of certain London opticians, the reason being that the said opticians were not such fools as to stock unsaleable articles. No doubt they could make high power opera-glasses fully equal to those "Montmartre" writes about, and would do so if there were any demand for them; but even supposing a power of, say, 12 diameters, were desirable for indoor use, it is probable that it could be obtained more satisfactorily by means of a binocular telescope. If any of my fellow-readers want a good opera-glass they will not be likely to do better than by getting one, at a fair price, from some respectable English optician. At any rate, let me advise them to see these wonderful glasses recommended by "Montmartre" before paying for them. **Experience.**

## EGG PRESERVING.

[24286.]—THINKING that perhaps some of your subscribers may feel interested in preserving eggs by a new and cheap process just given to the public by an American farmer of Coos County, Oregon, I inclose a copy of article taken from the *Prairie Farmer*, of Chicago, Ill., U.S. I am of opinion that sulphur alone would have answered the purpose, as it would seem that the acid fumes of the burning mixture effectually sealed the pores of the egg-shells. Can any of your scientific correspondents explain the action of mixture used upon the lime forming the shells? You can, if you care to print the article, make use of the queries in this, but please do not print the letter itself. **Saml. Haigh.**

Coquillam, British Columbia, April 28.

"A NEW EGG-PRESERVING PROCESS.

"After many experiments I think I have hit upon the right way to preserve eggs. It is inexpensive. I got my idea by seeing sea captains burn charcoal and sulphur to disinfect ships, kill rats, &c., with, carbonic acid and other gases, set free by combusbustion. Free carbon and sulphur fumes are death to living things, septic germs not excepted. Graphite and lampblack are carbon, and I chose lampblack for my experiment. Sulphur with lampblack sufficient to hide it were mixed together. I took a churn 20in. square, having a circular hole in one side, and on the 1st day of February, 1883, placed in it two dozen fresh laid hen's eggs and two goose eggs, filled a saucer about two-thirds full of the sulphur and lampblack compound and placed it on the eggs; set on fire with a match (it burns slowly and without endangering anything); put on the churn cover, pasting a paper over it to keep in all the smoke, and left it over night. On opening the churn I removed the eggs to an open paper box, and set them in the store-room. After four weeks they were examined, and found all right; the last of them were tested on the following 4th of July, and were as fresh as when laid. I broke one into a saucer, and placed it in the sun, and it dried out perfectly sweet. Two of the eggs were placed under a hen with other eggs. The fresh eggs hatched out, but she could not spoil the two which which had undergone the process; they came out as good as new. Use perfectly fresh eggs, and a dry, air-tight box. I don't pretend to say how long they will keep, but do know the result of my own test. J. HODSON.

"Coos Co., Oregon, March 14th."

## THE EDMUNDS THREAD, &c.

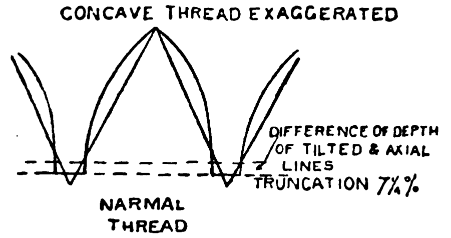
[24287.]—THE third-last par. of my last (24241, p. 235) refers to fitting by the slide-rest processes I have before mentioned, and not by hand-turning or special tools of other kinds. Curved tools, as mentioned by others, have their action limited to one screw, to one rake, and one diameter alone, and are not practically worth considering, unless we have the magical ability of "J. K. P." to convert an annular cutter into a spiral one by the simple process of reducing its diameter.

Last week I examined specimens of the actual "Edmunds" thread. The thread is as described, "beautiful," its clean, sharp appearance being enhanced by the very slight, almost infinitesimal, concavity of the thread-faces on the axial section. Two screws, with their axes parallel and teeth engaged, just show this curve with a light behind and a lens in front.

Practically, this minute concavity is the sum total of the case against it. The thread is non-reversible, only in that the reverse of the groove and thread sections are not the same; but in the sense Mr. Wenham sets it forth ("lopsided," and that a chuck could not go on either way) it happens that it is reversible—faultlessly so.

Mr. Wenham has treated us to no little circumlocution and false reasoning, one good specimen occurring in 24225, where he demonstrates conclusively what "Tubal-Kain" stated previously, that a point alone can trace the lines of a screw-thread, and that therefore it is not possible to cut a screw-thread at all.

The "Edmunds" thread is abnormal, even the sections on the zigzag line—called the *normal* lines by the Dr. and by myself to distinguish from *axial* one—are not of the depth of the named isosceles, though their sides are, as far as they go, true to name and a V point. The deviations are in all cases so very slight that it is no easy matter to deal with them at all by observation. I add a sketch of the thread upon the isosceles; qualitatively correct only, and to my best belief.



CONCAVE THREAD EXAGGERATED
DIFFERENCE OF DEPTH OF TILTED & AXIAL LINES
TRUNCATION 7¼%
NARMAL THREAD

The thread is too fine, in my judgment, for a lathe nose. I prefer eight turns only and a stouter thread; if the clearance at bottom was reduced by a 5 per cent. truncation of V, and 8 per inch adopted, it would be about right; but though threads similarly cut and abnormal, and apparatus to produce them are common, I do not think it is true practice to incorporate them with scientific work. With an increased rake, too, the factors would be increased in amount, and the thread would hardly be as strong as the normal; the gripping during "on" or "off" being also rendered greater by the more acute angle at the top of the curve, causing wear.

The thickening of top is at most an infinitesimal quantity, nothing to compensate for the concavity. I am not absolutely sure of its existence in the specimens I examined, though as the point penetrates less on the tilted than on the axial section, it looks a certainty as on the diagram, though again it is reduced in quantity by the obliquity of the axial section.

What Mr. Wenham's intentions are with regard to the impression to be left on the minds of inquiring members I cannot make out at all in the matter of hard and soft noses. We are to begin by softening them, then to avoid maker's lathes whose noses will not stand the test of a file corner. Then we see a particular maker animadverted because of spring temper noses, and alien makers advertised because their noses are hard; but finally (?) we are landed thusly. A hard cylinder is not to be used for centring, but a nose cut with a chaser (that must have warped in the hardening) under the guidance of a screw that has at least too much "back lash" to guide another tool truly, and this at a very slow speed and good genuine back-gear in, as well as all the jarring train of leading-screw wheels, &c., with slack bearings, spring, and so on—a ten-ton sort of process, seemingly.

All this to end in the much-decried and regretted soft nose!

Anyone who supposes there are no direct-acting high-class scientific methods of truly guiding revolving tools freely backwards and forwards supposes wrongly; and without any gear whatever in the guiding action, there is no difficulty in doing it. Mr. Wenham has raised several "bogeys," including that more or less one of "foreign competition"; but there is about as much "bogus" as "bogey" in the matters, each and all.

**Vulcan.**

## CAN A V-THREAD BE FORMED BY A LAP?

[24288.]—ON a spindle running in a lathe let a disc of paraffin wax be mounted to represent the lap. Take a finished V-threaded screw and press it on the lap so as to form an edge, each part of which is touched by the screw thread. The lap so formed will give the shape of one which, if made of proper material, would produce a similar thread to the one used to make the wax one. The lap will have an angle more acute than the groove of the screw. It is shown in Figs. 1 and 2. In them it will be seen that the bottom of thread is touched only at a point on a line joining the centres of screw and lap, and that from this point to A the lap cuts *a* side of groove, and from this same point to B the lap cuts *b* side of groove only. It will also be clear that the section of the lap cannot be that of the groove it cuts, and this, I think, is what misled Mr. Wenham.

**Glatton.**

FIG. 1.

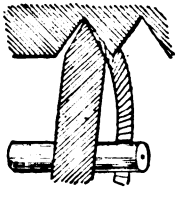


FIG. 2.

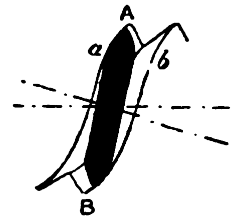


## INTERCHANGEABLE MANDRELS.

[24289.]—WHILE thanking "E. J. S." for his polite reference to my letter, I must again apologise if I have mistaken his meaning. I believe it was in connection with the front slide lathe that I last expressed in the ENGLISH MECHANIC my views upon the value of large bearing surfaces, and in practical work I have never failed to carry out this principle in every possible form. "E. J. S." perfectly understands the mechanical principles involved; but I would point out that there is a difference between two surfaces rubbing continually upon each other, and two surfaces which only partially cover each other at intervals. Take, for example, the cylinder of a steam-engine having a 2ft. stroke, and, although the motion of the piston is regular and constant, it will be found upon investigation that for a distance of about 5in. at either end of the stroke, the wear gradually decreases to *nil*. A further example in our more immediate vocation may be seen in the poppet cylinder of a lathe used continuously for boring or drilling, and which will inevitably show signs of unequal wear, the front portion of the head and the back portion of the cylinder being the most worn.

But what decided me against the long-cylindered mandrel-nose was the sacrifice of screw-thread unless increased length was given to the nose. A long mandrel-nose in the workshop is bad; it is more liable to injury, more time is taken in screwing chucks on and off, and the result is greater wear, without any adequate increase of stability or endurance. I would much rather have a short nose with a large shoulder-face, than a long one having but a small face for the chucks to abut against. In the *travel* which chucks would have to make over a long cylinder the abrasion is multiplied. So far as mere pressure goes after the chuck has arrived at its seat, the abrasion, though not lessened in its total amount, is divided up and distributed over a larger area; but the abrasion of pressure upon the Edmunds cylindrical "stop-surfaces" is infinitesimal. The value of the cylinder as a "stop-surface" to eliminate "eccentric variation" is not increased by any length beyond the thickness of a florin for small lathes; therefore the increased length of the long-cylindered nose, the conicity which would soon result from the abrasion of long travel of the cylinders upon each other, and the time wasted in putting chucks on and off were my reasons for objecting to this form of mandrel-nose. At the same time I endorse all that "Vulcan" has said (page 236, col. 2) in favour of the Edmunds cylindered mandrel-head, and I recommend all my customers to adopt it, as better, simpler, and cheaper. The mandrel itself may cost a little more than the old form; but, then, it gets rid of the costly, cumbrous, and ricketty transfer-chucks, while it will do anything, from the finest ornamental ivory turning to the manufacture of a small steam-engine.

Screws are the most important parts of mechanism, and the principles of all sound workshop fitting are involved in the questions now being discussed. No subject of greater importance than this has ever been discussed in the ENGLISH MECHANIC, and these letters are being read with great interest by practical mechanicians as well as by scientific amateurs. I wish some of our contributors would peruse over again Dr. Edmunds's last letter (page 189).

"Canmore" gives a clear and excellent drawing, Fig. 1 and Fig. 2, but I do not understand how he gets the rounded sides of thread, as shown in Fig. 3; nor do I see how it is that he draws conclusions which are different to the Doctor's. I am not sure that I always understand what "Vulcan" means, and his diagram seems wrong to me. Dr. Edmunds's tilting of the cutter-wheel to the rake of the thread does not mean that the cutter-axis is to make a horizontal angle with the lathe-axis, but only that the cutter-axis should be tilted in a vertical plane parallel to that containing the lathe-axis.

Those who read Mr. Wenham's recent letters side by side with mine will see which is the "angry" one. Mr. Wenham's ten-ton 18in. centre lathe with "a hardened mandrel" ought to be sent to the exhibition. I don't wonder at his objecting to the finest cast steel. Lathes of this calibre usually had their mandrels (I quote from the catalogue) "of best Yorkshire iron." I have known them to be case-hardened, but not always, and these were usually fitted into conical gun-metal bushes or parallel split bearings.

After stating that "some of our best lathe makers now true up their hardened steel mandrels with a diamond tool," we are told that there are two unknown makers in Berlin who do it. I cannot pursue this phantom any further, but no doubt some of our contributors will examine and report upon these lathes if there are any good points in them due to diamond tools.

Mr. Wenham puts this climax to his assertions: "at one time I should have made no hesitation in taking the contract for a gross of mandrels, every one of which when screwed into a test chuck finished in the lathe, should have the free or tail end running absolutely true, and, as I have said before, there are plenty of light turners who could be trusted with the job."

In the catalogue issued by the firm whom Mr. Wenham cites as the greatest authorities on these points (page 36), there is the following:—

"*Although all lathes of the same size, say 5in. centre, have their screws exactly alike, as to the diameter of thread, it is only by mere accident that the same chuck runs truly upon two different lathes.*"

This remark about such centring by means of the screw-nose will be endorsed by all mechanical experts who know their business. It was to overcome this difficulty that Dr. Edmunds has devised the cylindered and wide-faced mandrel-head. Mr. Wenham asserts that the present screw-nose will answer perfectly. Can contradiction further go?

**Edward Hines.**

Griffin Works, Norwich.

## LATHE MATTERS.

[24290.]—PERHAPS "Faber" will acknowledge that I am now a little further than I was on p. 237. What appears on p. 259 was intended for the previous week, but being very busy, I could not forward it in time. I have read "Hadah's" on p. 235, and at present hold the opinion that his last paragraph is erroneous. I do not know whence come the words in inverted commas beginning with "providing" down to "blank." They are all wrong, anyhow, as "Hadah" says, but his own correction is wrong. I find a 55° cutter making an eight-threaded screw produce about 60° angle of screw thread measured on the plane in which the axis of screw lies. The statement that a cutter of 50° will cut a counterpart V-thread is, as far as I have experimented, entirely wrong, too.

I am also at present absolutely sure in my inner consciousness that the italics beginning "there is no," &c., at bottom of middle column, p. 259, are wrong; inasmuch as the cutter cannot clear itself except on the *Faugh-a-ballagh* principle—that is, by clearing out a way for itself, which means something very different.

Also, at the top of third column, as far as I have gone, I do not agree with line 6. My threads come out rounded, not hollow, on the sides, and U-shaped at bottom, about ¼ of a circle, using a sharp V-edged cutter of 55°. I hope I have not misspelt the Irish motto of one of our most splendid regiments. Although descended from Brian Boroimhe, I do not include that tongue amongst my useful knowledge.

If there is any plagiarism at all about different numbers of threads requiring different cutters, Mr. Wenham certainly made the assertion before I did, and it is beginning to be received as true—at least in the sense in which I used the expression, and as I understood him to use it. J. K. P.

### LATHE MATTERS.

[24291.]—I have now seen the drawing and description of the lathe in the *Amateur Machinist* of March 7, referred to by Mr. Myall; it was kindly sent by Messrs. Barlow, of Manchester. I have written for a copy from America, and if you, Sir, will engrave it, I shall be glad to send it to you. It is most cheering to me to see several of the points we have been contending for so well carried out in practice. We have the front slide, vertical slide for milling, bored mandrel, with front apparently formed into a kind of Essex chuck, and the nose appears to be coned outside, not threaded, and the chucks, I suppose, held from within.

One word about the nose and screw question. Mr. Wenham says, on page 238, "With a good screw-cutting lathe they (screws) can be made quite as true as any cylinder work." Now, I thought we started with the supposition that that amount of truth was not sufficient; that is, that the degree of truth obtainable by the fixed tool is not sufficient for the production of screwed or plain fittings on which the interchangeability of a mandrel is to depend (see page 367 of last vol., and top of middle column); but that the surfaces required to be left with the finish of ring and plug gauges, and I never heard that these could be finished by the fixed tool. F. A. M.

---

[24292.]—Mr. S. Beeching (letter 24260, p. 258) has given two shaped tool holders for iron and other metals. These forms I have had in use for many years for wood turning; but of course the shape of the tools, especially the gouge, has to be altered. The gouge is made of a tube of steel, and has the merit of being capable of being sharpened all round at once, and a simple turn of the tube brings a fresh cutting edge. The tool B with me carries many shaped cutting tools. To enable different thicknesses of steel tools, and to enable the tools to be held more firmly, I have a thickish piece of hardened steel (tempered), a little hollow underneath, or rather bowed a little from end to end, and it is on this that the screw acts, and so the tool is held at both ends of the arched or bowed piece, and the screw does not mark, or what is more important, bend the tool. I have omitted to state that the gouge is held in a bar split at the end, and turned down like A, and the screw brings the two sides together and holds the tube (which fits the hole) very tightly. R. S. T.

### CUTTING SCREWS, &c.

[24293.]—My terminology is no doubt faulty; but I found a good deal of newly-coined terms in some letters, and used them as ready-made and to hand. I have used the word "normal" in its mathematical sense as well as in its "nominal" or contra-abnormal sense; but I do not think confusingly to anyone reading all letters from the beginning.

If I had been writing a treatise instead of discussing a non-momentous current question, I should have settled my terms more carefully, and at commencement.

I have spent some time over Dr. Edmunds's letters, and regret that all I have learned is how error clothed in much and semi-neo-technical language can be iterated and persisted in, plus the limit of my capacity to pursue a tortuous and not profitable reading without wearying.

The commencement of the discussion afresh "with clear and distinctive terms," &c., I am not prepared to undertake, and it will be some time before those terms are forthcoming—at our present rate or proportion of progress, a long time.

My case against the thread and its nomenclature is summed up in letter 24098, p. 129: "Whereas the thread is spoken of as 50°, neither section, axial or normal, is truly so; but the section of the groove or nut-thread, has a true 50° normal section. If nut and nose are to be alike, it is necessary to have the 50°, or other angle, axial." Dr. Edmunds says (24172, p. 189): "The object at which we are aiming is the formation of an angular thread derived from an isosceles triangle;" also see Fig. C, p. 562, No. 1040. If that is the object, and the lap wheel is as often described V-edged and tilted to mean angle of threads in the groove, then those remarks of mine and that letter were sufficient, if practically looked into, though I did not "demonstrate" much.

Mr. Wenham has not only stated and shown enough; but something too much. "Canmore's" diagram—a similar one was begun by myself, but thought unnecessary—is a very plain demonstration, though the angular rake-line should be a tangent to mean angle of mean diameter of thread, not to outer diameter and least rake, and it is not clear why the normal cross section on such minimum's vertical plane should be diagonally set on the page; but it is next door to "stereotomo-metrising" a wooden bench screw.

What occult property of the traverse is to produce spiroidal lines on the V-side along the serrated line, or series of short diagonals across the groove, I cannot divine; but unless we are prepared to measure threads for their nominal section on these diagonals and in the groove (as "Hadah" suggests), a thread cut by straight-edged V-wheels, as described will be unnameable. If we do so, we get in return an unsymmetrical and too deeply-cut screw, and an inferior one that breaks all the mechanical unities.

Dr. Edmunds's case seems to me to be thus: (1) He has cut fine screws that have hardly any apparent distortion, it not being discoverable by himself or others who have examined them, but the which distortion (concave axial lines) I found myself with the watchmaker's lens I often use as surely as I have eyesight, and that over and over again; this looking along the lines tangent to the contacts in axial plane, not *point blank*; (2) he is not familiar with large screws where the defects would be visible, and has involved himself very much indeed as regards the principles of accurate screws and screw-cutting by a "persistence of vision" for the helixoidal lines "turned in air"; (3) has been deceived by the angular set or tilt of the point tools often used to cut screws, by regarding such tilt as necessary, and a finishing process, whereas the tilt is given to get equal cutting-edges on the tool for quickness, without the trouble of hollow-grinding the top in an axial plane; (4) has not had to depend on his acumen in these matters, and as a total, is in the matter of his lapse "an untransformable geometric entity."

The workaday theory of screws and screw-cutting is simple enough. The factors "given" are the length, diameter, and axial section; with these, all else is ascertainable easily. For physical purposes, the attachment surface to shear altitude and angle to get surface and stress on it; longitudinal motion of a revolution to get power required for any given work and distance. A quantity of such work will follow from the above.

The shape, position, traverse rate, &c., of the tool all follow from the axial section. The screw to be cut requires to turn round so much faster or slower than the leading screw, as there are more or less turns in the same length to be cut in it, one revolution making each thread. This, with an example or two, will generally penetrate the average intellect, and once it has done so, he will work out his change-wheels like an automaton, and have a fair idea of what he is about.

Why we should be called upon to consider an impossible helicoidal trigonometry (24038) p. 103, as "the normal cross section to which regard should be paid in calculating the strength of the thread" I fail to see; nor why (24172), p. 190, "the curved line forming the base of the normal thread section would be one of the spiral lines of the normal rectangular helixoid"; ordinarily, the diagonal on a cylinder is elliptic.

It is beyond our mathematics to deal with a diagonal normal section cut by a plane as the sides are spiroidal and the base elliptic, save by the consideration of the plane triangle in the axial plane; in an unsymmetrical screw the triangles of neither section nor the thread itself would be considerable at all.

My last diagram reconsiders as both very correct and very necessary. My text referring to it, though parenthetical where it occurs, seems to me to be extremely clear, and very relevant to that calling it forth.

Primarily, we read Mr. Wenham's case of the "cedar pencil" or spiral on a cylinder with disc applied to show difficulty of lining latter to centre-line. Next (24172, p. 190), "If anyone will draw two circles touching each other, say, of the sizes, &c., and will then draw a straight line joining their centres, he will see that it is not possible to get the revolving cutter off the line of centres. Whether the axis of the revolving cutter is above or below (note) that of the screw to be cut, makes no difference whatever to the angle of the groove, inasmuch as the cut finishes on the line of centres." Then the axial inclination is easily given, and guidance got by the slide-rest.

My text is (24241) p. 236, "I send a diagram of such a cutter set for a quick screw, but at a maximum off centre—*below screw*. The angular set goes entirely to deform the thread, and its original purpose is gone, as the cutter has no inclination left to the pitch of the thread, but is at right angles to axis of screw in plan." Moreover, my diagram shows a cutter finishing on the line of centres.

It is the plainest complete disproof of Dr. Edmunds's proposition. If he has a slide-rest on links, one end swivelling on line of centres and others on line of the axis of the divided head, and that automatically adjust themselves before the inclination is given, the fact should be stated, for in no other case is his proposition true.

There is no difference, theoretical or actual, as to difficulty or necessity of aligning revolving tilted tools or fixed tools, provided the latter are ground on the sides alone and properly held and fitted on the slide-rest, as in the case of cutter bars in use.

If my text has been read as well as my diagram glanced at, I am more deficient in capacity to explain than I thought, or somewhere that factor is wanting.

That a square or even undercut thread could be trimmed by wheels coupled horizontally, "by cutting one side at a time .... with suitably sized cutters," I stated in 23945, p. 35, and I regard it as an easy-to-be-seen fact, Mr. Wenham's drill-cutter being only one set at the mean angle so as to act on both sides at once, but which can only be of small diameter.

It is *not* essential "in order that the tool clear itself, its plane of revolution must be tilted, &c." As I have (24241) stated, an upright parallel disc—one that runs on an axis parallel all ways to the screws, and cannot be set off line of centres—can be turned to such curves as its sides come in contact with till it bottoms and cuts a true thread, though rounded at bottom, and by sizing it, it can cut on the normal section. Moreover, I have found a tool that cuts true screws, and that inclines on its cutting edge to the exact duplicate of the screw being cut, *but in the opposite direction*, and that has specific advantages of its own.

When Dr. Edmunds has done writing upon remotely relevant pennies, screws, planes, &c., and has a terminology pretty well considered, and has also got on a sound elementary basis by sectioning some real screws of visible dimensions, I shall then be ready to look into his results. I cannot afford either time or labour for no or retrograde results.

The model mandrel and its de-modelling by the lapsus in its thread formation have been very long in hand already, and the element of error has been frequently well pointed out. When it is out of hand—as it is now, so far as I am concerned—I am willing to assist with "terminology," or any subject of interest (sufficient) as I can spare time.

The definition bisected by "a rectangular helixoid" reads well, but my own "axial section on apex or centre of its summit," was framed for simple language, and to show in diagrams where the "helixoid" is not comprehensible.

As for the "lady's fan," I do not use one; and from what I have seen I should say represented wave motion rather than anything in a screw; and I also think that the majority who cut screws will be more familiar with the screw-propeller, and understand it better as an instance that a screw-thread winds from lengthwise to across as its depth increases upwards and *vice versâ*.

Why the tangent line that "Canmore" shows should be called a "hypothenusal line," or where the right-angled triangle gets to or comes from when that line mysteriously winds into "helixicoidity," I cannot understand.

The grooves on cylinders cut by a wrongly-tilted V-cutter do not seem to me to be U-like particularly: they seem to me to begin in a decided Gothic arch (perfect when tilt is to bottom angle of groove), running then to elliptic and circular arcs. This U is taken from "J. K. P.'s" diagram, Fig. 3, page 237, "on the flat," which diagram is misleading, inasmuch as one side (the left) is shown with the straight line of the V in it, and the other, especially at the top, with an elliptical curve alone, and the sides should be alike.

I fancy our "G. O. Mechanic" has been hurried, if not worried, over this discussion, and a good deal of time and space all round might have been better employed. I agree with him as to clearance, but cannot get my annulus to split its edge and wind spirally by turning it smaller; it begins to cut off the thread at the other side.

The last two paragraphs of letter 24263 that once more "settle the case out of which this discussion arose," and "refer to the general proposition," if written by a responsible pen, would be the acme of folly in practice and the climax of that quasi-deduction that has befooled mechanics so often in the past and still does so. That anyone whose knowledge of screws is based on plane trigonometry should by simple assertion thrust aside a tool I have spent some valuable hours in ascertaining the efficiency of—in fact, this discussion has trespassed no little on time that belonged to more important work—seems to me to be a case calling for the use of space, if space were only valuable for such purposes as above. "As I have before shown" is not the case; "as before stated" is more to the point, and error cannot be converted into truth by reiteration, even when the latter process is an encyclopædic neo-technological one.

No helical line whatever is the shortest across any number of thread turns if taken separately, and the "therefore" does not follow, as curved lines cannot be as short as straight ones. The radial altitude remaining constant, "the normal section will have the smallest angle, the shortest sides, and the least area, as well as the shortest base line," has no reference or truth with regard to screws.

The real case stands thus: when the diameter of the screw is infinite and the depth of thread 0, the above is true enough, but when the thread has depth to the axial line and width, then the so-called "normal section" cannot be cut, but we get a spiro-elliptic lozenge. The critical point where the "normal section" passes into this lozenge is about where the thread's base-length and cylinder's or shank's diameter are the same, the former being measured in an axial plane. In this screw the base of the "normal" section is a diagonal or longer of the square of which the axial section's base is only a side approximately, and apart from the curvature of its sides, the normal section has the longer ones —in a thread the height equal to the base, about half as long again,—and the area may be many times that of the axial section, and the greatest, with height equalling base about twice and a half.

The critical point at which the "normal" begins to approximate to the plane goniometry cannot be found, but exists somewhere on the road to infinity.

If our attention is confined to the groove, we get into an equally absurd predicament, for the "base line" is somewhere or other beyond the nearer bottom of the groove.

That "to cut a screw that approaches the last limits of theoretical accuracy is impracticable" is undoubtedly true with reference to a model mandrel; but for other purposes, such as physical and micrometrical apparatus, such screws are cut; and in revolving tools, Mr. Wenham's drill, the bevelled disc, and the oblique-edged cutter I have several times named, will all do it on any material.

What I have stated with regard to this oblique tool "on the flat" is quite true: that it would not work on such an infinite diameter and clear unless itself of 0 diameter, or having extra motions on its teeth, I did not state, and it is beside the principle at issue to do so.

But that it will work correctly on screws other than plane trigonomo ones, I have ascertained, that, provided that it be sufficiently small to clear and set to rake at bottom of threads, this rake is somewhat of a matter of indifference when both screw and itself are small and there is plenty of clearance, as it will come, if made as described on page 125, No. 1,046 (24075) rightly up to the most projecting section—the axial one. It may be used as either cutter or lap with fixed abradant, and when set to mean angle of threads, made of same diameter as screw, and the two revolve at same velocity in opposite directions, the theoretical action is almost perfect. I send sketches this time. It would lap a smoother surface than a drill, and could be run much faster on periphery.

The best finishing process, and about the only theoretically accurate one, is by facet grinding and a floating abradant. For a screw, segments of a nut, duly to area and edge angles, held together by springs, and with guide to give due increase of pressure towards ends and away from centre, to prevent hollow grinding, these nut facets would have to revolve at same velocity and in opposite direction to screw, to prevent centrifugal action, heaping up the abradant unevenly and on one summit.

Lastly, one of these discs with oblique edges will cut symmetrical screws, all scale models of one another, or systematised, through a very large range of diameters and numbers per inch.

As to "men may come, and men may go," &c., I am now one of the going description, and I leave the field to those of the other kinds.

May 25th. **Vulcan.**

## THE NEW TIME.

[24294.]—Even after reading opinions adverse to the change from our present method of reckoning to the 24-hour system, I fail to see any difficulty in the way of the change which cannot be surmounted. The question of counting 23 and 24 strokes is, I consider, fully answered by "F.R.A.S." and "A. S. L." ("E.M.," Feb. 6). That of the difficulty in recognising the figures on dials could easily be remedied by the use of a revolving dial which, through an opening, would show the hour. To business men and others the new reckoning would, in my opinion, be a great boon, and the adoption of a "universal time" for international communications still greater.

When we come to the astronomical change, I am, however, at variance with "F.R.A.S." I have read that the Astronomer Royal has adopted the new reckoning, and that "the change was easily made from January of this year." Now, Sir, I would ask any astronomer whether, in a case where constant reference must be made to the *Nautical Almanac*, as must be the case at an observatory like Greenwich, some confusion must not arise occasionally? Even Prof. Oppolzer, whose expression in favour of the change Mr. Christie gladly welcomed, considered the change should be deferred till the new time is adopted in almanacs. The head of English astronomy advocated the change at Rome, and it would have been much better had he, before inaugurating so radical a change, taken some means to ascertain the opinion of astronomers on such a question. His colleague at Washington issued an order directing the change in astronomical reckoning to be made, but has had to withdraw it in consequence of the opposition of the superintendent of the "American Ephemeris." Heron, Forster, and Tietjen have declared themselves against the change; so that the heads of American and German almanacs agree in resisting adopting in haste and repenting at leisure. The director of our national association has not been heard on the subject; but the hydrographer (who knows how a change will be felt by seamen who use the almanacs), is against it. So much for those in high places; and now for one or two remarks on the arguments.

A prominent advocate of the change considers it essential that the civil day should change when most civilians are asleep; how this is consistent with changing the astronomical day when astronomers are in the midst of their work, I cannot imagine. Another difficulty I have been unable to surmount (even when almanacs are changed), is on which day would an observation be put down when it was taken partly before and partly after midnight; say, for example, an observation of Jupiter's satellite at transit; and again, a star observed at 11.59 p.m., would be a day different, for reduction, to one at 12.1 a.m. To my mind, the official organ of the Greenwich Observatory was about right in saying "It is impossible for the change to be made in observatories until it has been previously made in the great ephemerides . . . until the chiefs of the principal nautical almanac offices have agreed to introduce the change, no forward step can be taken." And again: "The change should not be made until astronomers are unanimous upon the subject, or at least, until those favouring the change are so greatly in the majority as to render the dissent of the minority a matter of no consequence. The change should then be made at some common fundamental epoch adopted by arrangement among the astronomers of the world."

**Conservative.**

[24295.]—I am sure you will allow me to point out that the "advocate of change" (letter 24249) contents himself with very little more than a mere verbal criticism of my letter 24247—hardly even defends his own case; certainly advances no new argument, as I had hoped he might do, of advantage. The change may give immunity from confusion to him and such as he is; but to the men, women, and children less learned than himself, there will be constant confusion for somewhere between ten days and the end of time.

I expect to find ere long the idea relegated to the limbo of forgotten fancies, even in spite of the difficulties of astronomers and professors of mathematics who find their *route* in the pages of Bradshaw a more bewildering task than the search for the train of a comet through the labyrinths of most mysterious and complicated calculations.

**Civicus Olim.**

## ACHROMATISM, &c.—VIOLINS.

[24296.]—It will interest our optical readers to know that I have recently received from Mr. W. A. Haren four numbers of the *American Journal of Science*, containing important papers upon object glasses. These papers deal exclusively with achromatism and the secondary spectrum; spheric aberration is not touched upon. They are, of course, entirely mathematical; but the analysis is new, and the method of treatment interesting. The first paper is by Prof. Harkness, and it will appear as soon as possible.

Every reader of this paper will be glad to learn that the health of our friend, Mr. J. A. Brashear, is much improved; and ere long we may hope to see his appearance in these correspondence columns again.

With reference to the subject of violins I may remark that since my last letter I have been enabled, through the kindness of "Country Parson," to examine the curves of a Strad. and of a Guarnerius model, and I shall have more to say upon them in the course of a week or two; but it may be as well to state, for the information of Mr. J. Towns (query 56665), that if he is working on the Strad. model, Mr. Heron-Allen's book on "Violin-making" is the very thing for him. It contains full-size drawings of a Strad. and of a Guarnerius violin, together with instructions for properly dimensioning the various parts. If these two full-size drawings, together with two small diagrams showing the proper finished thicknesses of back and belly could be had separately from the book, they would be a boon which numbers of amateurs would not be slow to appreciate; and if these few words of mine should chance to meet the eye of the talented author, I am sure many would rejoice if they induced him to offer the drawings separately.

**Orderic Vital.**

## A NOVEL CLOCK.

[24297.]—I should like to describe for the benefit of the readers of the English Mechanic a novel form of clock, for which I took out provisional protection some time since; but, of course, have not the slightest objection to anyone making a model for himself, if not for sale.

The idea admits of endless variations; but I shall only describe the original model which I made myself, as any ingenious person can develop and improve upon it.

The case of the clock is a 9in. cubical box of wood, which is ornamented by staining the wood, painting in water-colours on the stain suitable designs and mottoes, and varnishing over all. The top of the box has a 6in. hole in the centre to admit of a china bowl, resting in it as a basin in a wash-stand, but with its edge flush with the wood. Round the inner edge of the bowl two rows of Roman figures from I to XII are painted in gold, one row near the edge of the bowl and another about half-way down. I found the easiest method of spacing these figures correctly to be to paste paper over the interior of the bowl, divide off by compasses, and mark the figures on the paper with sulphuric acid, which, on exposure to heat, eats the paper away, and forms a rough stencil plate, easy to remove by warm water when the gold is painted in.

A wooden or indiarubber image of a duck, swan, or other swimming bird must now be procured, and a small bar magnet, such as those used in toy boxes with fish, inserted in its head with (say) the N. pole to the front. A toy fish with a similar magnet with S. pole in front may now be gilt, and weighted with snipe shot until it floats comfortably below the surface of water, in a natural manner.

Next take a cheap American clock, such as one may readily obtain for 4s. 9d. Remove the face and the hands, and attach to the hour and minute axles respectively horizontal bars of wood. At the extremity of the bar attached to the hour axle fix a light bar magnet vertically with S. pole uppermost, and to the bar of the minute axle a shorter magnet with N. pole uppermost. The minute bar must of course be shorter than the hour bar, in order to go round freely inside the latter.

Now cut away a little of the bottom of the wooden case, so as to admit of the clock lying flat on its back thereon. If it be thought worth while to rigidly attach the clock to the case, of course a hole must be cut for the winding screw; but I prefer to simply lay the clock down and withdraw it for winding when required.

The clock being now in position, and a bowl inserted and filled with water, it will be seen that the magnet on the hour axle will draw round with it the duck or swan, and that on the minute axle the fish, thus presenting the pleasing appearance of a bowl of water with two moving figures showing the time with no visible attachment to machinery. My own model is a very handsome ornament to a drawing-room, and cost me about 10s. A most beautiful object could be made in the same way by carving and decorating the case so as to make the bowl appear an artificial lake, with overshadowing trees and devices of roots, ferns, &c., for the figures.

I may add that my model was made in January last, and has gone well ever since. Very feeble magnetic power is sufficient, and if light bars and magnets be used the clock will keep excellent time. I hope I have made myself intelligible, as I have no time to draw a diagram. I hope also that if any amateurs construct a like clock they will let me know their experience, and I trust to the good fellowship of the English Mechanic contributors and readers not to infringe the patent by making clocks of this kind for sale.

**Garrison Gunner.**

## VOSS'S ELECTRICAL MACHINE.

[24298.]—I send a short description of the principle of Voss's (more correctly Töpler's) electrical machine, in which I have tried to avoid the old misleading "two-fluid" nomenclature, basing the explanation on the following facts:—

1. That round every conducting mass charged with electricity there is a region or "field" of force which diminishes in intensity with distance from the centres of electricity.

2. That electrical energy tends to move from points at high potential to points at lower potential in the field.

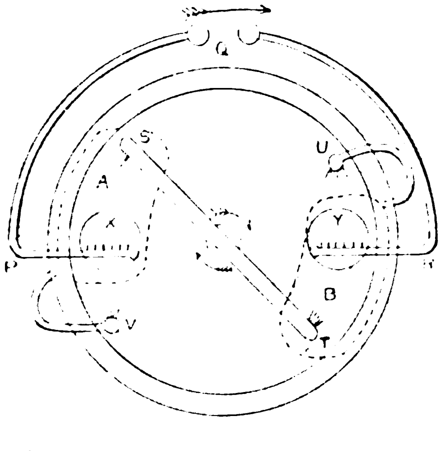
In the annexed diagram, A B are the paper inductors at the back of the fixed plate; X Y are two of the series of tinfoil carriers on the moving plate; P Q R is the main conductor, the rods being carried above the plates, as in Wimshurst's machine, for clearness; S T is the cross conducting arm; U V are the bent arms connected with the inductors, and furnished with metallic brushes which touch the carriers as they pass.

Let one of the inductors, A, be raised to high potential by any method.

Then the system of conductors P, Q, R, lies in a field of uneven potential, falling off towards R, and takes, as usual, the average or mean potential of the field. Therefore P is in a region of higher potential than itself, and electricity is transferred from X to P (by the row of points), and R is in a region of lower potential than itself, and electricity is transferred from R to Y. Hence X is reduced to a state of low potential, and Y is raised to a state of high potential. And the portion P Q of the main conductor having received electricity is at high potential relatively to Q R, which has given up electricity. Hence a gradient of potential is established between the two parts, P Q and Q R, and electricity tends to transfer itself in the direction of the arrow across the interval at Q.

Now let X be moved round until it reaches the cross-arm S T at S, Y will at the same moment come in contact with T; and since the carriers are still in the field of A, a second transfer of energy will take place similar to that just explained, so that X will be reduced to still lower potential, and Y raised to higher potential.

Next, let the rotation of the plate be continued until X touches the bent arm U connected with the inductor B. Then, since it is at low potential, electricity will be transferred from B to it, and B itself will be reduced to low potential. Similarly, when Y touches V, electricity will be transferred from Y to A, and the potential of this inductor will thus be raised above that due to its original charge.



Then the conditions are the same in character as at first, but intensified, A being at higher potential than before; B being at lower potential than before. Thus, there is now a steeper gradient of potential between P and R, so that the tendency of electricity to pass across Q is increased.

Lastly, when the plate has made just half a complete turn, X comes where Y was at first, and the cycle of changes begins again; X now gaining electricity owing to the low-potential field of B, and Y losing electricity (as X did) owing to the high potential field of A.

What is said above of X and Y is true of all the other pairs of carriers on the moving plate as they come in succession opposite A and B. Hence, as the plate rotates, there is a continual transfer of electrical energy from one side to the other, and the difference of potential between the inductors A and B soon becomes very great, and thus a very steep gradient of potential is maintained between P and R, so that discharge takes place at Q through some distance of air.

The function of the cross-arm, S T, appears to be to cause the change in the electrical condition of the carriers, under the influence of the fields of the inductors A and B, more decidedly and effectively than can be done by the main conductor, P Q R (as in the Holtz machine), in which there is high resistance whenever there is an interval of air at Q. The main conductor system, then, serves for external work, while the cross-arm does the internal work of maintaining and increasing the difference of potential of the inductors.

The whole action may be roughly compared to the work of setting up and maintaining a current of water in a pipe connecting two cisterns by laddling water from one of the cisterns to the other, so as to keep up a constant difference of level. **E. R. P.**

---

### MAGNETIC MOMENT.

[24299.]—QUERY 56546 has given rise to answers so numerous and so contradictory that a few observations on the subject of the moment of a magnet or "magnetic moment" may be useful.

There exists a good deal of confusion in terms of misunderstanding on this subject. The magnetic moment of a magnet is a quantity dependent on the magnet itself, and quite independent of the intensity of that field of magnetic force which is due to the magnetism of the earth or other cause. The moment of the couple, or, more shortly, the "couple" exerted on a magnet when displaced from the magnetic meridian is a quantity perfectly distinct from the magnetic moment. This couple tends to bring the magnet, when displaced, back again into the magnetic meridian, and it is in confounding this couple with the "magnetic moment" that some of the answers to the question have gone wrong.

Suppose an ideal magnet of pole strength $m$ and distance between poles or length of axis $l$. Then the magnetic moment is $m\,l = M$ (say). Now, the unit strength of magnetic pole is that strength of pole which repels a similar pole at unit distance with a force of one dyne. The dyne is the unit of force on the centimetre-gramme-second system of units, and all magnetic and electrical units are now based on this system: we therefore measure $l$ in centimetres. It must be noted that "pole strength" is not measured in dynes. Pole strength is a derived unit, and is got from the equation

$$\frac{m\ m'}{d^2} = F$$

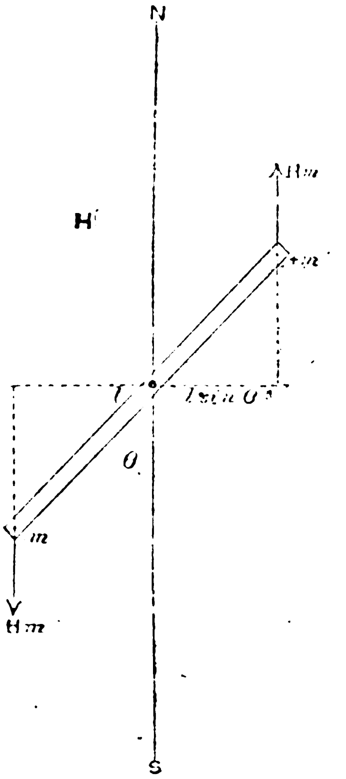
Where $m$ and $m'$ are two poles, $d$ is the distance apart, and F is the force in dynes with which they repel each other. In fact, the "dimensions" of pole strength are $L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-1}$, whereas those of force are $L M T^{-2}$.

It cannot be too strongly emphasised that, in experiment, the quantity which we always deal with in a magnet is its magnetic moment. In an ordinary bar-magnet it is impossible to locate the position of the poles with accuracy, or to determine the length of the axis. It is the product of these two quantities or M—*i.e.*, the magnetic, moment that we always deal with in practice.

Suppose, now, that we have the above magnet, of pole strength $m$, and length of axis $l$ displaced through an angle $\theta$ from the magnetic meridian, which we call N S, and suppose, also, that it moves only in the horizontal plane. Then the couple, G, tending to bring it back to the meridian is—

$$\begin{aligned} G &= H\,.\,m\,l\,.\,\sin.\ \theta \\ &= H\,.\,M\,.\,\sin.\ \theta \end{aligned}$$

where H is the horizontal intensity of the earth's force (H = 0·179, nearly, in London).



Now in the query (56546) $m = 3$ units of pole strength, and $l = 10$ centimetres, so that $M = 30$. The strength of field is here 10, so that $H = 10$, and we have

$$G = 10 \times 30 \times \sin.\ \theta.$$

When $\theta = 90°$, or the magnet is at right angles to the direction of the force,

$$G = 10 \times 30 \times 1 = 300.$$

I do not wonder at many readers being in some confusion on this subject, as the complete understanding of the units employed is a matter that needs close attention.

**Lewis Edmunds, D.Sc., LL.B.**

### A NEW DEMONSTRATION OF THE PARALLELOGRAM OF FORCES.

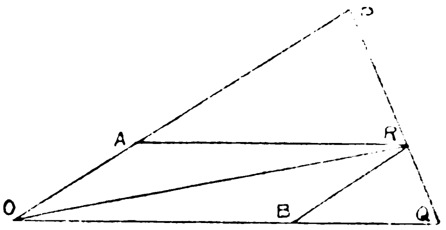
[24300.]—I BEG to submit for insertion in "Ours" what I venture to think is an original and simple demonstration of that important and interesting problem known as the "Parallelogram of Forces." I hope that you will insert it, and that it will elicit an expression of opinion from some of your talented correspondents.

Lemma 1. The spaces passed over by moving bodies are (*cæteris paribus*) inversely as the masses.

Lemma 2. The impelling forces of moving bodies are (*cæteris paribus*) directly as the spaces.

Lemma 3. The centre of gravity of two bodies divides the line joining them, so that the ratio of the segments is inversely as the adjacent masses.

Proposition.—If the adjacent sides of a parallelogram represent the direction and space which would be passed over by a body when two given forces act upon it separately, the diagonal will represent the direction and space which would be passed over when the forces act conjointly.



Let O be the initial position of a mass, M, and O A the direction and space which it would pass over in a given time when acted upon by a force C; also O B the direction and space which it would pass over in the given time when acted upon by a force D. Then, if the parallelogram, O A R B, be constructed, its diagonal, O R, will represent the direction and space passed over by M in the given time when the forces C and D act conjointly.

Now, since M cannot contemporaneously pursue two directions, let it be supposed, when acted upon by C and D, to divide (without resistance) into two portions, G and H; and let O P, O Q be the spaces passed over in the given time by G and H respectively. Then (Lemma 1)—

$G : M = OA : OP$ ..............................(1)
And $H : M = OB : OQ$ ......................(2)

Therefore, from (1)—

$$G = \frac{M\,.\,OA}{OP}, \text{ and } OP = \frac{M\,.\,OA}{G}.$$

Therefore, from (2)—

$$H = \frac{M\,.\,OB}{OQ}, \text{ and } OQ = \frac{M\,.\,OB}{H}.$$

Join P to Q. Then the equation to P Q when put into the form

$$\frac{x}{a} + \frac{y}{\beta} = 1, \text{ is } \frac{H\,.\,X}{M\,.\,OB} + \frac{G\,.\,Y}{M\,.\,OA} = 1.$$

Now this equation is always satisfied, irrespectively of the values of G and H, by $x = OB$, $y = OA$. Hence, G and H being the only variables, P Q always passes through a fixed point; which, obviously, is R, the other extremity of the diagonal O R.

Further, because at the end of the given time, G and H are found at P and Q respectively, and that

$$\begin{aligned} G : H = \frac{M\,.\,OA}{OP} : \frac{M\,.\,OB}{OQ} &= \frac{OA}{OP} : \frac{OB}{OQ} \\ &= \frac{QR}{QP} : \frac{PR}{QP} = QR : PR, \end{aligned}$$

the point R is (Lem. 3) the centre of gravity of G and H.

Hence it is manifest that the effect of the simultaneous action of the forces C D upon the mass M is equivalent to the translation of M from O to R.

Moreover, the locus of R (the centre of gravity of G and H) is the straight line O R. For the direction of O R depends upon the angle A O B and the ratio O A : O B, which depend upon the direction and magnitude of the forces C and D; but C and D are invariable, consequently O R represents the path of M when C and D act conjointly.—*Q. E. D.*

Corollary.—Since O A, O B, O R represent the spaces passed over by M in equal times, these same lines will also represent the magnitude of the impelling forces (Lemma 2); hence, if the adjacent sides of a parallelogram represent the directions and magnitudes of two forces which act upon a body, the diagonal will represent the direction and magnitude of the force which is their equivalent.

**S. Stokes.**

---

### TO E. M. NELSON.

[24301.]—IF the condenser mentioned by "Amateur" is the one I have in my mind, the top lens is nearly a hemisphere, the other is a plano-concave of flint and biconvex of crown. I should say that if you silvered the convex surface and ground off the apex, you would spoil it, and gain nothing.

The amount of flint in an object-glass depends entirely on the formula by which it is made, i.e., the idiosyncrasy of the maker. **E. M. Nelson.**

### MINERAL-OIL LAMPS.

[24302.]—J. HUGHES has claimed to be a "practical man," and on that claim sets all other persons at defiance. He says, in fact, that he has worked at his subject for 40 years, that we know nothing about it; but that he, having proved all by test and experience, can give us a lesson or two.

Well, then, why does he not enlighten us? To my advocacy of metal reservoirs, he insinuates that I am a mere theorist, and calls upon me to test the cooling influence of glass against the heating of metal, and while suggesting that my understanding may be enlarged by so doing, almost dares me to publish the result.

My reply was short, and to the effect that I had long since proved that the maximum heat of mineral oil during 10 hours in a copper reservoir was 69·2 Fahr.

Here was a complete answer to J. Hughes, for that temperature is not even the heat of a summer's day, and is from 30° to 60° below evaporation point. Now, will J. Hughes be kind enough to give to the public his knowledge of the heating of mineral oil in a copper reservoir.

23rd May. **J. D. Shakespear.**

### CRANK AXLES OF LOCOMOTIVES.

[24303.]—YOUR correspondent is quite right in stating that the grain of the iron in the web of the crank is in the wrong direction, and this will account for the fact that fractures usually occur where the inside web joins the crank pin.

I think no greater recommendation of the suggestion made by the Board of Trade upon the Penistone accident, that all big ends should be taken down weekly, can be given than by the fact that the number of flaws detected in running sheds last year exceeded half the total of axles broken in running.

I have also good authority for attributing the great breakage both of cranks and of truck and carriage-axles on the M.S. and L. Railway, to the frequency and severity of the curves existing on that line.

Mr. W. Stroudley, in a paper on the Construction of Locomotives, stated that by allowing more breadth in the four blocks, the engine would be prevented from leaving the rails, even if the axle broke, except in crossing points. Now by the use of the Joy valve-gear, space is given for 9in. of bearing, and also 5½in. for the crank-pin, together with ample room for inspection, in the case of Mr. Webb's new L. and N.W. three-couples.

Another solution of the question is the compound passenger engine of the L. and N.W., which has its single inside crank formed by the metal being bent into shape, an arrangement which keeps the grain in the right direction, while the application of force directly in the centre reduces side-play to a minimum.

Lastly, the strains on the crank-axle seem to be caused as follows:—

(1.) *By the reciprocating motion of the pistons.*—Hence it is more likely that the axles of the express engines should break than those of goods engines, as the extra leverage obtained over the smaller wheels gives an earlier cut-off, and lessens the strain.

(2.) *By side-play.*—This is proved by the large proportion (1·5 : 1·9) of straight axles broken last year as compared with that of cranked axles, it being well known that engines with straight axles and outside cylinders are most liable to oscillation.

(3.) *By curves, and possibly tightness of points.*—This is not sufficiently relieved by the bogie, or radial box, but is now allowed for in some "single" engines.

Surely the resolution of these into tensile and crushing strains would give an answer to the question whether steel or iron should be used, since the tensile strength of iron is 60,000lb. per square inch of section, while that of steel is 130,000. (Bourne).

Is it possible that inclined cylinders may, by their direction, obviate a certain amount of side-play? **Beginner.**

[24304.]—"WILFRED," p. 260, refers to what has been said by the Railway Servants' Society—that the fibres of iron run in the wrong direction in the crank webs; but he further goes on to say that there is an invention by a firm he names, to get the fibres in the proper direction. If this can be done it is a grand thing, so I anxiously wait for full details or a sketch of this way of making cranks. In consequence of the Railway Servants preferring "iron axles," Messrs. Vickers and Co. have just issued a statement to show the good work of some of their *steel* axles, and as the figures refer in a great degree to Midland engines, perhaps it will be considered in the "E.M." by our friend "Midland."

**Crank-Axle.**

### COMMUNICATION CORDS ON RAILWAYS.

[24305.]—THERE can be no question that as a matter of safety that Scotch express train *should* have been stopped and the brake-blocks removed from the step board of the carriage; but I think a "Carlisle Passenger" did quite right in not using the cord. The Company would doubtless argue that it was "not sufficient reason," and he would therefore have found himself removed from the train at the next station and charged before the magistrates. What is "a sufficient reason for using the cord"? This has never been defined by law. Perhaps Mr. Stretton will give his opinion upon the matter?

**Lex.**

### THE AFTERGLOW.

[24306.]—SINCE 30th March the glow, after a period of inactivity, suddenly returned to nearly its former splendour; though, strange to say, subjected to marked variability from day to day—being bright one evening, but almost nil the next.

On the 7th and 8th inst the light was very strong, and huge ribs or streams stretched right across the sky to the eastern horizon, terminating there over a sort of dark circle. These streamers are seen after the arc of light in the east has faded.

The first, or rather red glow, lasts for about 25 minutes, when, as before, it settles on to horizon in a deep orange band; the sky now again brightens up, and a *third glow* goes through the same stages, lasting for another 30 minutes. On the 7th the sky seemed clear and the stars bright; but, on using the 6in. on Jupiter, the planet presented, most of the time, just a luminous blurr, with spurious images flapping on its sides, the same as I have before noted of Venus, and which seemed to me caused by the glow-producing medium.

Transvaal, 10th April. **John Ballot.**

## REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the tit e and number of the query asked.*

[54825.]—**Salt, &c.**—"Dens" agrees with me that nature's law is uniform; but why this should be his reason to begin with a civilised man, instead of a lower type of man, I fail to understand. If they are found, when found at all in "older formations," and only with the most primitive stone implements accompanying them, it seems to me most natural to begin with "Palæolithic man." The whole of "Dens's" reply confirms me in doing so. Naturally the most remote ancestors of our race would show the fewest remains, and those imperfect, left undestroyed by the tooth of time and incessant agencies at work to destroy and recreate, only under quite exceptional conditions. I cannot agree with "Dens," "if man had lived for a thousand centuries, &c., we should not be able to find a rood of ground without a skeleton in it." As is well known in geology, the older the strata the fewer the fossils, until we come to those which contain none at all; hence it follows, the older, the lower the type of fossil, whether of beast or plant; the less is also their number, regardless how numerous they may have been when covering the earth in life. In short, "Dens" rather mixes things when he says, "I begin with civilised man," and, in conclusion, says, "It won't do to speak of these men as being primitive." Again, if "Neanderthal skulls" have been found, it is beyond my scepticism to conclude, with "Dens," that "it is as yet only supposition if such men ever lived."—F. W. H.

[55879.]—**Cutting Iron (U.Q.)**—If "Younker" has cut his circle of 1-50th of an inch thick, I hope he will tell us how. I should turn a wooden faceplate and fix the iron ring on it truly central. Then take a piece of wood about 2⅞in. wide by ½in. thick and fold a piece of emery cloth over the end. Use this as a turning tool to grind the groove out. The edges will not be sharp, and must be finished with a scraper held so that the edge is well below the part held in the hand. I think I should try to do without a rest for the latter part of the operation, many using an upright piece of wood to prevent side motion of the scraper, and nipping this between the scraper and the thumb of the hand holding it.—GLATTON.

[55952.]—**Sheet Iron.**—Cut out one piece and use it as a template to mark off the others. Lay it on a plate, and, with a steel scriber trace the outline. Then cut the plate to this line.—GLATTON.

[56243.]—**Fuses for Projectiles.**—To "GARRISON GUNNER."—Having been away for the last few weeks, I have only now seen your answer to my query. I thank you very much for the information you have so kindly given. I shall not trouble you to look up the "Changes in War Stores," for I know what trouble that would entail, and, besides, you have told me all I wanted to know. I have been so much interested in your description of the new fuses, particularly of the "time and concussion," that I am about to write to the D. A. for permission to procure the chromo-lithographs of them from the R. L., Woolwich.—EX-GARRISON GUNNER.

[56318.]—**Owls.**—If "Agricola" will put caustic soda into the holes and runs of the rats, they will go away at once, and never come back. Should a new lot come in, repeat the dose. It is a most thoroughly effectual and safe way of getting rid of such vermin.—DENS.

[56358.]—**Chronic Cold.**—In answer to "Ora et Labora," the following prescription for a lotion to be snuffed up the nose into the mouth and spat out will be of infinite value:—Sodæ bicarb.; sodæ biborat.; sodii chorid., aa. grn. vii.; sacch. alb., gr. xv. Mix; dissolve in breakfast cup of tepid water.—Q. A.

[56335.]—**Wheel Gearing** (53635, Vol. XL. p. 181).—The inner pitch line will not be at the same distance as the outer one. Its position relatively to the point and root of the tooth will be the same as the outer one is to its point and root; but the distance between the lines representing the pitch circle, the point, and the root on the small side will be so much less, because the length of the tooth is less. In the sectional drawing of the wheel, the lines representing the pitch, the point, and the root upon the large diameter are laid down. They are then severally prolonged to the centre of the wheel, or to that point where the line of bevel cuts the centre of the shaft, or, speaking more correctly, to the apex of the cone. The breadth of the teeth is then marked upon these lines; and where the intersection occurs the relative distances of the pitch line, point, and root for the small side are pricked off with compasses. The top and bottom dotted lines are those on which the centres of the radii for striking the flanks and faces of the teeth are placed, for the obvious reason of obtaining uniformity of shape all round. The distance of these lines from the pitch line is not a constant distance, but will vary with the diameter of the wheels and the shape of tooth adopted. If you look on p. 250 of the number in which your query occurred you will see a case in point. Three sets of wheel teeth are there figured, struck with Willis's Odontograph; and in the case of the smallest wheel of the three the striking line for the roots is a long distance without the circle of the teeth. This can only occur with the smallest pinions of a set; but in every case it is necessary, in order to attain certain results, to fix upon the shape of the teeth, and then to adopt the striking lines to them. The thickness of wheel teeth from ½in. to 4in. pitch, advancing by quarter inches, and expressed in nearest fractions of an inch, should be as follows:—

| in. | in. | in. | in. | in. | in. | in. | in. |
|---|---|---|---|---|---|---|---|
| ½ | ¾ | 1 | 1¼ | 1½ | 1¾ | 2 | |
| $\frac{7}{32}$ | $\frac{11}{32}$ | $\frac{7}{16}$ | $\frac{9}{16}$ | $\frac{11}{16}$ | $\frac{13}{16}$ | $\frac{15}{16}$ | |
| 2¼ | 2½ | 2¾ | 3 | 3¼ | 3½ | 3¾ | 4 |
| $1\frac{1}{16}$ | $1\frac{3}{16}$ | $1\frac{9}{32}$ | $1\frac{13}{32}$ | $1\frac{17}{32}$ | $1\frac{11}{16}$ | 1¾ | 1⅞ |

A third and fourth is not quite correct for the relative lengths above and below the pitch line. A better proportion is 3 above, 3½ below; or, to be more accurate, 5½ above, 6½ below, and this gives quite enough for bottom clearance.—J. H.

[56360.]—**Tandem Bicycle.**—"Bike" does not give sufficient particulars; but it is not a matter for surprise that he does not get on well "with different riders." The tandem bike is a rare goer when you get two riders to run together; but it takes a good deal of practice even when the two are fairly matched. There are not many tandem bicycles in use.—ESSAR.

[56364.]—**Wire Blinds.**—This query is rather a puzzle, for the difficulty seems to be in the want of sharp edges to the gilt letters. If the querist cannot do without, he should paint his letters first, and when dry lay on the gold size, taking care that its edges are sharp. Gild when tacky, and the edges of the letters will be sharp also.—ESSAR.

[56367.]—**Cocoa-Nut Oil.**—I thought it was the odour that was objected to, not the colour, for cocoa butter is white. Sturtevant's process is as good as any, and consists in steaming the oil in a wooden vat, and adding to each ton 6lb. of sulphuric acid, and 12lb. of hydrochloric acid. Time is allowed for settling, and the oil is drawn off.—NUN. DOR.

[56374.]—**Globe Telephones.**—One wire is for the bell circuit, I suppose; the other two for the telephone.—E. G.

[56377.]—**Electrical.**—No. 24 wire is quite fine enough for electro-magnetic machines.—NORMAN.

[56397.]—**Feeder for Organ Bellows.**—Why not make two feeders worked by one handle, so that the opening stroke of one feeder is the closing stroke of the other?—J. W.

[56398.]—**Boiling White.**—The proportions are 3lb. of cream of tartar to 4lb. of grain tin or shavings. About two gallons of water will be sufficient. Boil, say, for half an hour, and then put in the brass, previously cleaned. Does that last word throw any light on the failure? This question has been answered many times.—Nun. Dor.

[56484.]—**Varnished Wall Paper.**—"C. D. R." says, "You might as well clean dirty windows with paraffin as dirty wall-paper." He will be surprised to hear that the best thing to clean either dirty or dull windows, or any other glass, is paraffin oil.—R. C. N.

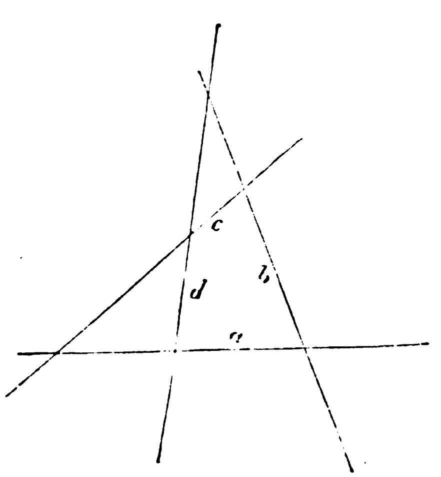
[56518.]—**Organ Building.**—The questions asked under this heading could be better answered by a correspondent more thoroughly acquainted with pipe-organ construction than what I profess to be. My experience is chiefly in connection with reed organs, and beyond the matter of simple repairs and tuning, I do not profess any great knowledge of pipe-organ construction. I have never attempted to make organ-pipes of any kind, and have never had any desire to attain to that art. Perhaps some of our organ-building correspondents will kindly reply to the questions put forth on p. 222. The information required will doubtless be of interest to many readers. If the querist had any intention of building a reed organ, I should be pleased to help him in any way I possibly could. I will, however, offer a few hints to the querist on the subject of organ-building. He is no doubt aware that a small pipe-organ will take up as much room (if not more) as a large reed-organ. Though the volume and quality of tone obtained from good organ-pipes is superior to that obtained from reeds under any conditions, a large reed-organ is preferable to a small pipe-organ, for the following reasons:—1. The former can be made to a convenient size, suitable for any private dwelling, and yet to contain as much variety of tone as may be found in a large instrument of the latter class. 2. In a reed-organ we can have from two to four manuals, each of which may contain reeds, voiced to imitate effects similar to that found in the larger class of pipe-organs. Other advantages of a large reed-organ over that of a small pipe-organ could be explained if necessary. One set of good organ-pipes would cost as much, if not more, than four or five rows of vibrators. My remarks refer to the American organ-reeds and cavity-boards. The American organ is the nearest approach to the pipe-organ in quality of tone, and I think that the majority of persons will admit that a large, well-constructed American organ, with two or more manuals and pedals, is superior to a small pipe-organ—that is, if a variety of tone effects are required.—G. Fryer.

[56531.]—**Gramme Dynamo.**—On p. 223 read: "Armature consists of 16 segments of No. 18 S.W.G., and total wire weight of 2lb. 2oz.—usual Gramme core (solid). Wire on field magnets, No. 16 S.W.G., and total weight 14lb. 4oz."—Vandu.

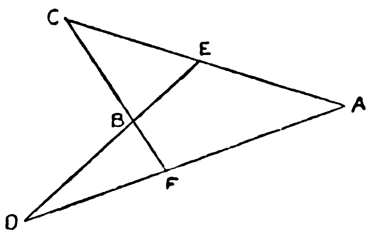
[56530.]—**Harmonium, &c.**—To "Harmonica" (p. 223).—I offer the following advice, if he likes to take it: You say that you are about to add two rows of reeds to your harmonium. Are you sure that your bellows is large enough for two extra rows? If not, I should advise you to first ascertain this. If you can obtain the required amount of wind, buy a complete pan suitable for the entire number of rows of vibrators required, you will then have no need to trouble about the sizes of pallet holes, or yet to ask whether the reeds would "sound right if simply screwed on top of holes." A soundboard, or pan, for one row of reeds, consists of a series of 61 channels or tubes made to a certain scale. The use of these channels or tubes is to give body of tone from the reeds, and also to subdue some of the harshness or reediness of tone which would result, if the reeds were merely screwed on a piece of wood with holes for the reeds to vibrate through. You cannot actuate the reeds on the suction principle with a pressure bellows, like that found in harmoniums; you must use a suction bellows, which has a contrary action to that of the harmonium pressure bellows. As I can partly guess what you require, I will advise you to dispose of your harmonium, and either make or purchase an American organ containing the required number of rows of reeds. If you want the harmonium and American organ principle combined, I should advise you to make a two-manual affair, the lower manual on harmonium principle, and the upper manual on suction principle with American organ reeds. I will send all necessary particulars for accomplishing this, if requested. As the query now stands, to accomplish what is suggested in it is an impossibility, for obvious reasons. I will, however, answer one question with regard to the matter as to "how the valves [pallets] are opened in the American exhaust principle?" The valves, or pallets, are situated immediately under the reeds, and cover a series of longitudinal apertures which are cut out of the mortise board on which the tubes containing the reeds are secured. Each pallet is provided with a spring of sufficient power to keep each pallet firmly closed. The pallets are actuated by plungers, which are small pieces of wood. The plungers pass through a portion of the wood forming the tubes. They are made steady in action by the employment of a guide-strip or guide-board. You will see this illustrated more than once in very recent numbers of the English Mechanic. When the plungers are pushed down by the keys, they actuate the pallets.—G. Fryer.

[56547.]—**Geometrical.**—I find that this problem, which has attracted some attention in these columns, is capable of further development. If we join the centres of the four circles, and thus form a quadrilateral figure, it will be found that a circle can be described passing through the four corners of this figure, and also through the point where the four circles intersect, and thus we have five circles intersecting in one point. Also, if we draw the diagonals of the quadrilateral, each of the angles made by the diagonals and the sides will be equal to one or other of the angles to be found in the original figure. The proof of this is somewhat difficult. I wonder if "Hemisus" or "T. H. L." could put this in as neat a form as they have succeeded in doing with the first part of the problem. In this complete form, the problem becomes one of considerable elegance.—M.I.C.E., Bath.

[56547.]—**Geometrical.**—"J. C." and Mr. Dwyer see difficulties in my answer to the first part of this query. In the figure *a b c d* are the four lines, and *a b c*, *a c d*, *a b d*, *b c d*, are the four triangles. Their difficulties are of their own making. There is no question of "twelve lines" or of "equal lines." The proposition deals with the four triangles always and necessarily formed by drawing any four straight lines (not limited in length) in a plane. "Hemisus" has given a good proof of the property enunciated.—L. Edmunds.



[56547.]—**Geometrical.**—In the two replies to this query (p. 242), the conditions of the problem appear to be lost sight of. We are required to draw a figure with four straight lines of given length in which figure there are to be four triangles, and then to prove that if we draw circles circumscribing each of these four triangles, the four circles will intersect each other at a certain point. In the first reply we are shown how to describe four separate triangles with four straight lines, which is nothing to do with the problem, and in the second we are introduced to a figure made up of eight straight lines, and as many triangles. Evidently the figure that Todhunter had in view was something like the one in the annexed diagram, where we have the four straight lines A C, A D, D E, and C F, and the four triangles A C F, A D E, C B E, and D B F. I have not drawn the circumscribing circles, to avoid confusion in the diagram; but this can easily be done, and it will be found that the four circles will cut each other at a certain point, whatever the length of the lines may be or whatever shape the figure may be, provided it fulfils the required conditions. I have not worked out the geometrical proof, but the drawing of the figure alone (which will comply with the conditions), makes a good puzzle, and is rather a curiosity.—M. I. C. E., Bath.



[56550.]—**Sawing.**—To J. M., a Sawyer.—I have been sawing some elm and ash into plank; my saw is 6ft. 6in. long, 10½in. at the top, and 2in. at bottom; teeth ⅝in. apart. I intend doing the sawing myself, and I do not mind spoiling some to learn, for it cost me about four times as much to buy the plank than to buy the tree and sawing included. I have done two pieces of ash into eight planks well since I sent the query, but the third piece very bad; it seemed to get worse all the way to the end of the 12ft. length, and then it was ¼in. or more hollow. I somehow thought it was because the saw was getting blunt, so I sharpened it, and the next cut went very much better. Perhaps you will give full particulars how to set and sharpen it; and if you write giving all particulars how to begin on a tree, and so on all the way through into planks, all the tools, &c., what are used, and what sort of saw is used to cut curved pieces over the pit, such as felleys, &c., with drawings, if possible, I think it would be a great help to many as well as myself, for it is a subject I have not seen treated on in the English Mechanic, and I have them all from No. 1.—Alabama.

[56558.]—**Lincoln Cathedral** contains no "stone beam." The remarkable arch of 23 stones, so miscalled, was apparently built as a strut, to keep apart the west towers, when the 13th-century masons, who were finishing them and planning the vaulting, apprehended some settlement of the towers toward each other. Their west corners were well separated by the great arch of the front; but their eastern must have shown some symptoms that this clever device has effectually stopped. The 23 arch stones are of uniform section, only 11in. deep, 21in. wide, and so chamfered below as to reduce it to about 195in. super. The clear span is 28ft., and the form a pointed arch extremely obtuse, the middle being but 20in. higher than the north springing, and but 8in. higher than the southern. Thus the whole suspended rib contains not quite 38 cubic feet. The radius of the southern half is about 100ft., but of the northern 112ft., and that end is loaded for about 8ft. with some 9 cubic feet of rough masonry; but the south or higher end, for a less distance, with about half as much. Nearly 14ft. of the middle are the bare arch-rib. These particulars are from W. A. Nicholson's accurate engraving in *Transactions* R.I.B. Architects, 1841. The 22 joints are normals to the two curves, and are thought not to contain any joggles. Of course, the structure creates a thrust, readily calculated, of many times its weight, or certainly many tons; but does not transmit any from any other arch. According to S. Ware's "Tracts on Vaults, &c.," 1822, Tract ii., p. 21, there is a very similar arch, but heavier and still bolder, in the Jesuits' Church at Nismes, constructed by one Cubisol, of which I would gladly hear anything more.—Harrisian.

[56563.]—**Medical Coil.**—My reply to this query seems to have been a cause of offence to our enlightened correspondent, "C. D. R." I congratulate "C. D. R." on his own reply to this query (p. 242), and on his discovery that mine is nonsense. It seems to me that "C. D. R.," admitting that he himself could not answer the query, is deeply offended if anyone else should answer it. We are reminded of the fox who had lost his tail, and who went about trying to persuade the other foxes that it was the correct thing to have no tails. The quotation from Montaigne which "C. D. R." advises me to lay to heart might sometimes be effectively remembered by himself, especially that part of it which refers to "clutter" and "little pittance" of knowledge. It may interest "C. D. R." to know that "Bobadil's" authority for his information is Angell's textbook, which, of course, may be entirely wrong. Will "C. D. R." be good enough to "enlighten" us on this matter by proving his statements, and showing where this well-known book is at fault? Nothing whatever was said about four electricities. Two were mentioned—positive and negative; and if "C. D. R." wishes enlightenment on the alphabet of the science he professes to teach, I shall be delighted to describe an experiment which proves the separation of the two kinds of electricity by an ordinary voltaic cell.—Bobadil.

[56564.]—**Dynamos.**—To Mr. Lancaster or Mr. Bottone.—I do not care to advise as to the winding of such a Pacinotti ring as that described, as it would surely be a failure. The cogs are much too thick and the spaces too narrow and too deep to be of any use. The field magnet cores must be much heavier, at least 3½in. in diameter. I will give another plan if you desire.—Selimo Bottone.

[56569.]—**Boiler Query.**—To "Boswell."—In answer to your reply, the boiler was made at Bowling in the year 1870. So, therefore, it is 15 years of age, and the plate is Bowling brand. It is all single riveted, the rivets are ¾in. dia., the joints are lap joints, and the first cone tube is 10ft. 2in. from the front of boiler, and there are ten tubes in the boiler, five in each box; the boiler pressure was 75lb. up to 1880, when it was lowered to 70lb., at which pressure it is working. There are no stays at the bottom of boiler, but there are four at each end at top. There are no longitudinal stays in. Could you be so kind as to tell me what alterations to make, so that we could raise the pressure up to 75lb. again with safety, or if it is impossible to work at 75lb. any more? Say what pressure it would be safe at if we got it altered. The plates seem to be good and sound. Of course it has had pretty hard work, and has yet. I am much obliged to "Ex-Blacksmith," and will try to follow his advice.—SAMMY.

[56573.] — **Chronic Rheumatism.** — To "B. Sc.," PLYMOUTH.—Many thanks to "B. Sc., Plymouth," for his kind and prompt reply to above, I now wish to ask him (and others who may reply) for further information, as I wish to try electricity. Should it be what is known as a coil worked by a battery or a magneto machine? If a coil, what battery should be used?—should it be a broken or continuous current? Could I have some arrangement, to apply while in bed, as I am extremely susceptible to cold; am afraid of exposing any part of the body to the air for more than a few moments together. Please give full particulars for the application of electricity. Have taken many medicines with but little benefit.—A MANY YEARS' SUBSCRIBER.

[56578.]—**Electric Bells.**—To H. S. BEACH.—I readily accept your kind help. I do not quite see how you make the line resistance 200 ohms, since the connections are all made parallel with the stations and not all in simple circuit or series. The bells are not large at all—small 4in. single-stroke bells I intend fixing. One of the stations being a long way from the others I thought a relay would be advantageous there, and also by having a relay at each station I could do with a fewer number of cells (Fuller), five or six at most. I may at once mention that they are telephonic stations between different places of business, each place having its own number of beats. I will gladly avail myself of "H. S. B.'s" diagram of connections also.—ELECTRA.

[56580.]—**Tricycle Pedals.**—I am not a mechanic, but as a cyclist think there ought not to be much difficulty in curing the fault in this correspondent's machine. Why not try a neat iron washer filed to a proper thickness, so as just to allow sufficient play to the pedal? In my own machine I stop all rattling by using thin leather washers lubricated with tallow, though probably these would not do for pedals, the friction being too great. As for spring washers, I know nothing about them, and fancy that, if procurable, they would not be near so efficacious as a pair of plain iron ones.—LITHIUM.

[56587.]—**Telephone System.**—If "T. J." is familiar with incandescent lighting on the multiple arc system, he will find, if he joins up a few telephones according to diagram shown in issue of 24th ult., that each telephone receives a portion of the current in the same manner as incandescent lamps do. The following diagrams may enlighten him a little:—

FIG. 1

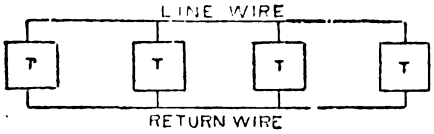


FIG. 2.

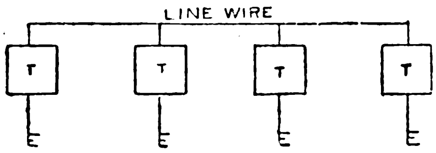

In diagram No. 1 a return wire is shown, and, of course, two leading-in wires are necessary in this arrangement. In diagram No. 2 earth is substituted for the return wire. If a telephone circuit is short, a return wire might be run; but if the circuit is a long one, it will save expense by only running one wire, and putting earth on at each telephone, as shown in No. 2, only one leading-in wire being necessary, this being soldered on to the line wire, which may be continuous (without break) from beginning to end. The success of working a circuit in this manner will depend on the earth being good at each station. With this arrangement I find that induction from other wires (such as telegraph circuits) is somewhat diminished. Also when electric tremulous bells are used in connection, no relays are required, as would be the case if joined up in series; and if a telephone gets out of order, or the line wire breaks, it will not stop the whole circuit, so that faults are readily localised.—R. F. S.

[56580.]—**Tricycle Pedals.**—"C. D. R." says, "Why not put in ordinary iron washers?" Well done, "C. D. R." You are certainly getting on. Could "C. D. R." put a washer on a tree without cutting off either the top branches or the roots or splitting the washer into two semicircles and then putting it round. Just in the same way, perhaps, he could possibly get the washer on to the crank in the right position. "C. D. R." does not forget to pounce on Mr. "Bobadil" this week, for that gentleman kindly volunteering information. If "Bobadil" was paid for his advice, it would be a different thing altogether. Wherever did you obtain your information? Dear me! Extraordinary! Could you illustrate with a few diagrams, for the benefit of engineers and amateurs alike, this method of yours? You know it is a tricycle with a crank and not a bicycle in question. Now, do you see, dear ("C. D. R."), I have found "Invicta's" method to answer properly. I ride a front steerer myself, and it was on going down hill with legs on rest that the shaking of pedals became most annoying. Now, "C. D. R.," try and discover a few more methods by next week, and for the future do not try to answer questions about which you know nothing at all. If, instead of waiting for someone else to answer "Medical Coil," you had done so yourself, it would have been better.—U. C. S. W., Cardiff.

[56604.]—**Differential Equation.**—In looking again at this query (supposing it to be given in good faith, and that the first term is a misprint), I think the equation must be meant for—

$$\frac{d^2y}{dx^2} - a\frac{dy}{dx} = 0.$$

This is a "partial differential equation" with three variables, $x$, $y$, and $z$, the solution of which will be—

$$y = m(2z + ax^2 + nx) + c,$$

where $m$, $n$, and $c$ are arbitrary constants. This may be proved as follows: First consider $z$ as constant, and differentiate twice; then $\frac{d^2y}{dx^2} = 2ma$. Now consider $x$ as constant, then $\frac{dy}{dz} = 2m$. Multiply this by $a$, and subtract one result from the other, and we get the original equation. I am rather curious to know how such an equation can have arisen. Perhaps "H. H." would say whether it is from some geometrical construction.—M.I.C.E., Bath.

[56611.]—**Junket.**—Obtain one quart of new warm milk, a small piece of rennet (juice of calves' maw), allow to stand and get cool. Then add two tablespoonfuls of brandy, a little nutmeg, a layer of white sugar; lastly, a layer of Devonshire cream. For teetotallers the brandy need not be added.—A DEVONSHIRE GIRL.

[56617.]—**Stained Skin from Wearing Black Stockings.**—Try a little vinegar or a weak solution of oxalic acid about the strength of vinegar. Rinse afterwards with hard water. Should there be any roughness of the skin, use vaseline.—VERAX.

[56620.]—**Steam-Carriages.**—About four or five years ago a steam tricycle was made by a gentleman named Parkyns (of Woolwich, I believe), and exhibited at the Stanley Show at Holborn Town Hall, London. The cost was to be £40 each machine. The fire was fed with methylated spirit, which was turned into gas and burned in the furnace. The machine seemed to answer every expectation. But before any orders were taken, a friendly test case was tried before Mr. Partridge at the Court of Woolwich or Greenwich, and it was decided that the machine came within the Acts relating to road locomotives, one clause of which, in addition to those enumerated by other correspondents, is that the tires must not be of a less width than 12in. Since the above decision nothing has been heard of the machine, and it would be foolish to attempt to build one with the intention of running it on the public road to any advantage. Since writing the above, I see that a description of the above tricycle is published in the "E. M.," Vol. XXXVI. page 153.—F. SMITH.

[56620.]—**Steam-Carriage.**—This question of a steam-propelled vehicle seems to be perennial; but it is, so far as the public roads are concerned, happily answered by legislation. No doubt any English Mechanic might safely be trusted with a steam velocipede or a steam carriage, but the experience of the frequenters of the river in connection with steam launches is not conducive to expressions of joy and welcome as regards steam carriages on public roads. The replies on p. 266 are amusing—they are so very innocent. One gentleman says that weight, heat, and smoke are all against steam-engines for common roads, which is true enough; but he proceeds to say that a better motor could be had to work with gas, air, electricity, or "even hydraulics." The "even hydraulics" is rich. The Parkyns steam tricycle, which you illustrated on p. 153, Vol. XXXVI., is about the best thing of the kind, but I will venture the opinion that if that were driven along the road at the speed of a fair average tricyclist, it would be "heavy on repairs"; and I have not yet had the pleasure of seeing a practical design for driving by gas, air, or "hydraulics," even on paper, though I have seen Prof. Ayrton's electric tricycle, which I fancy was not altogether economical. "C. D. R." must be a very young man, for he delivers the opinion that "steam carriages would have been an institution years back were it not for the restrictions placed upon them," with an evident belief that he knows all about it. Let me ask him, then, how it came about that all the early inventors of steam carriages gave it up as a bad job, for the "institution" is coeval with the century, and Capt. Dick Trevithick was at least as much of a genius as can be found nowadays. I mention Trevithick because there is indisputable evidence that he and Vivian constructed a steam carriage which actually did some good work (it is illustrated in Vol. XXXII., page 507); but Cugnot, in France, and Oliver Evans, in America, were before him by about thirty years. James, Gordon, Gurney, all built steam carriages or coaches (the last-named ran his on the Cheltenham and Gloucester road), while there are plenty of people still living who remember Hancock's steam coaches which ran between the City and Islington, and the City and Stratford. Some of the steam coaches accomplished as much as 128 miles in a day, and a steam drag made for Sir C. Dance did run from London to Brighton in about 6½ hours. That was in 1833. The Editor of the *Mechanics' Magazine*, writing in his number for Nov. 3, 1832, said: "We do not expect to see steam power ever applied with economy to quick travelling on common roads." The following year saw a great development of steam coaches, which really did in their way work very well; but as to economy—ah! that is just it. Reuleaux, in his "Kinematics of Machinery" (Kennedy's translation, p. 235) says: "We have the problem of steam locomotion on common roads, which has been so feverishly taken up again within the last few years, but the solutions of which seem doomed to eternal incompleteness, for they are self-contradictory. It is desired to make something which shall be a machine, but in which at the same time the special characteristic of the machine, the pairing of elements, may be disregarded." No steam carriage can be successful on a common road unless it has thick rubber tires or elastic wheels, which, so to speak, lay down the other "element" in the shape of a rail. The cost of those rubber tires and their excessive wear made the steam coaches altogether too expensive. Trevithick, Gurney, Hancock, Heaton, and the others all tried hard during the first third of the present century, and gave up the steam carriage as a bad job. We have their experience and our, of course, superior intelligence, superior tools, superior materials, &c., and we really ought by this time to make a steam carriage for use on the common roads—even on those just coated with broken granite or flints. I thought, however, it might be as well to call attention to the fact that steam carriages are not exactly new ideas, and that, as a matter of fact, nearly every conceivable scheme in connection with them was thrashed out half a century ago. There are plenty of good designs for steam carriages in early volumes of the ENGLISH MECHANIC; but, whether or not the "restrictions" upon their use are unfair and unjust, I seem to have a scintilla of an idea that they will never become an "institution" unless they run on rails. Those are the only "efficient and satisfactory steam carriages" we are likely to see.—NUN. DOR.

[56622.] — **Lightning Conductors.** — The essential points to be attended to in erecting a lightning conductor are—(1) to obtain good earth contact; (2) to see that the sectional area of the rod is sufficiently large; (3) to have the leads and all metalwork about the roof, &c., in metallic connection with the rod, and (4), to let the apex of the same consist of one or more sharp points, elevated well above the highest point of the building. The first and third of these essentials are of the utmost importance. With respect to the first, the rod should be joined to a good-sized earth plate, and sunk in damp soil; or, if a stream is available, capital "earth" may be made by carrying about 10ft. or so of the conductor along the bottom, and burying it in the mud or clay. In cases where there is neither marshy ground nor stream, some engineers recommend digging a trench—say, 10ft. long and 4ft. deep, and laying the end of the conductor along the bottom, well bedded in gas-coke, that substance affording a large surface contact with the soil. Too much care cannot be given to obtaining good ground contact, and yet it is a point frequently neglected when the erection of conductors is in the hands of non-scientific persons. In many cases the end of the rod is merely thrust a foot or so into the accumulation of soil, brick-ends, &c., at the foot of a chimney or other erection—an arrangement far worse than useless. The shape of the conductor is immaterial, its efficiency depending on the sectional (solid) area which, in the case of copper, should not be less than one square centimètre: the area of other materials being in proportion to their conductivity. Conductors are frequently passed through glass insulators when near the ground; but this is a matter of little importance. They may be joined directly to the holdfasts without any detriment. As to the amount of space protected, Prof. S. P. Thompson says that Preece has calculated "that a lightning conductor of a given height above the surface of the ground will protect from the external action of electricity a conical space, the radius of whose base is equal to the height of the rod; but whose side is hollowed in the form of a quadrantal arc." It is well to have a conductor tested on completion, with a view to ascertain its resistance (the French Minister of Posts and Telegraphs recommends 25 ohms as the maximum), and, more particularly, to prove the soundness of the earth contact. If this were done generally, there would be some curious results obtained with many so-called lightning conductors.—LITHIUM.

[56622.]—**Lightning Conductors.**—The things to be guarded against are—(1) leaving any strikable point conductorless; (2) leaving a gap, or a fusibly slender neck, anywhere in the conductor's length; and (3) leaving the foot too far from permanently moist earth. The question, "What area does a conductor protect?" involves a total fallacy, as Sir W. S. Harris long ago proved to the Admiralty. No strikable point is protected by another point. Thus, no ship's mainmast is found to protect another mast, or even the jibboom. Nay, where all these four had conductors, a mainyard has been struck. In short, every point that might be touched by the middle of a plane disc, say, of 100 yards diameter, without touching aught else, is a strikable point; but whatever could not be so touched is unstrikable. Having gone to see every point struck within a few miles of London during some 30 years, I found no exception to this. Of course, it follows that no isolated country building can have less than three points needing protection, and most have half a dozen, while the majority of town houses have none in danger. Again, as our buildings all have metal gutters, and rain-pipes to the ground, any bit of special conductor lower than the eaves is a blundering superfluity. But as the successive pieces of descending pipe cannot be electrically connected, as by solder, a short copper band should connect each with the next. The smallest gap in conducting-line is dangerous, as the spark leaping it will fuse the nearest points, as it also will if they alone touch, for they then form a fusibly slender neck. Any neck must be considered fusible whose section is less than ·3 of a square inch of wrought iron, or probably twice as much of cast, or a seventh as much of the purest commercial copper. If this could be had as inelastic as lead, it might be the cheapest material; but any that we find is elastic, the more so the more impure, and probably the amount needed for safety costs more than what is needed of iron. The most economic form will always be that having most cooling surface to a given weight; therefore riband, the wider the better. Insulation is of no use whatever, nor yet making conductors rise above the point protected, nor elaborate sharpening. Slightly ragged ends, naturally left, are just as effective in lightning prevention as needle-points. Any proper conductor prevents many flashes that, in its absence, would occur.—HARRISIAN.

[56624.]—**Newmarket Direct Railway.**—ERRATUM.—For "1878" read 1873.—W. B. P.

[56634.]—**Piccolo.**—In reply to "S. R. P." the Boehm piccolo in D measures 30 centimètres long; 25 centimètres from mouthhole to the lower end, the lower joint being 19 centimètres long. The bore at the cork is 11 millimètres; at joint, 11 millimètres; at lowest key, 7·5 millimètres; and at end, 9 millimètres. The hole diameters, beginning at the lowest, are in millimètres. 8, 8, 8, 7·8, 6, 6, 6, 5·8, 4·8, 4·8, 4·8, 4, 4—13 in all. As to the mechanism and positions, that would take some trouble to explain, and I think there are not a sufficient number of our readers interested; but if "S. R. P." advertises his addressI will try to give him the information he desires.—VULCANITE.

[56636.]—**Australia.**—In last week's "E. M." "books had better be taken" appears. I intended to write "boots," &c., as all English leather goods are better than colonial.—ROSICRUCIAN.

[56640.]—**Detachable Stock for Revolver.**—It entirely depends on the class and make of revolver. If it is, as many are, fitted with a ring screwed into the end of the stock, then the matter is easy enough. Because all you have to do is to fit the shoulder stock with a projection to slip over the lump just behind the hammer, and a set-screw taking into the thread where the eye of the sling ring holds all firmly. Supposing the weapon has no sling ring, then it means fitting the stock to embrace the butt of the revolver, and holding it firm by means of a set-screw and covered clip. If one saw the weapon, it would be easy to quickly devise a plan. For lightness I had a stock fitted to a revolver made from stout steel wire, and for all practical purposes it answered admirably.—INVICTA.

[56642.]—**Petroleum.**—There is hardly likely to be any water in petroleum; the water is perhaps in the cans or bottles in which the oil is stored or obtained. I have never noticed anything of the kind. Dry the inside of the lamp with a piece of blotting-paper or cotton waste, and see that all cans and bottles are perfectly dry before use.—OS.

[56644.]—**Resistance Coils.**—To MR. BOTTONE.—I quote from Mr. Sprague's work, p. 162. The following sizes are suitable: Single ohms, No. 18 to 21; 10 ohms, 20 to 29; 100 ohms, 25 to 34; 1,000 ohms, 32 to 40. The following are about the lengths of 1 ohm: No. 18, 18ft. $2\frac{1}{2}$in.; 20, 9ft. $3\frac{7}{10}$in.; 24, 3ft. $1\frac{6}{10}$in.; 26, 1ft. $11\frac{8}{10}$in.; 29, 1ft. $1\frac{3}{10}$in.; 34, $6\frac{6}{10}$in.—S. BOTTONE.

[56645.]—**Small Gas-Engine.**—I must apologise to "J. H." for interposing in a matter addressed to him personally; but my interposition is intended to be in the interests of the general reader, so that I feel sure he will not feel, as he would otherwise be justified in doing, that I was, in dealing with a personal question, committing a grave discourtesy. The suggestion I would make is this: Gas-engines seem to occupy the minds of more than a few of the readers of this journal. That any amateur runs a very great and double risk in designing and making himself is equally sure, because gas-engines *cannot* be designed like steam-engines, and the money sunk in fruitless experiments has been simply immense. Not only this, but the patent rights are now so many, that it is hardly possible to get to work without treading on the toes of someone, and one patent agent I have had mentioned to me is doing a good business in looking up all infringements, &c., he can discover, and assisting the patentees to mulct the (in many instances) unwitting infringers. Now, there is a way out of the difficulty with safety and ease; and having this in mind, I mentioned, in conversation with a well-known gas-engine patentee, the difficulties. After some discussion, at length he stated his willingness to advise his company to grant a free license to bonâ fide amateurs only, who are, from the extent of their means, unable to buy a gas-engine, and who are not themselves engineers. To such he would be prepared to advise the company to issue a special free license to make one engine only. And this must also be backed up by a legal undertaking to that effect. On my remarking that the clause to make but one engine would be very hard in the case of an amateur who had, for instance, underrated his demand for power, I was told that in such cases, on the facts of the case being laid before him, he would, to prevent as far as possible any hardship, advise his company to take over the smaller engine at a reasonable price as a second-hand motor, and grant the person in question an enlargement of the license to enable him to make a second engine under the circumstances. Under these conditions, and that the engines so made would be at all reasonable times available for exhibition to intending customers, who would be properly introduced by the company's local agent, he would furnish tracings of either a vertical or horizontal engine, and either of the compressing or non-compressing type, and any infringement of patent right would lie with the company, and as no experiments would be needed to get the engine perfect it seems to me a good proposal. At any rate, I throw it out for any remarks on the scheme, which looks to me both feasible and good.—INVICTA.

[56648.]—**Bichromate Battery.**—If you connect up for quantity the different sizes of the batteries will not matter, but if connected in series of course it will. You must then have about the same surface exposed (to the action of excitant) in each cell, and surely you can compare the sizes of the two zincs better than anyone at a distance can do it for you. The internal resistance is the R. offered to the passage of the current through the battery; for instance, if you place the plates at a distance from each other you would have a greater R. than if you place them close together.—OS.

[56648.]—**Bichromate Battery.**—You can connect up your cells either in parallel or series. If you connect them up for intensity or series, the E.M.F. will be double that of one cell, because the E.M.F. only depends on the material used, and not on the size of the cell; but if you connect them up in parallel or quantity, you will get more than double the current the small cell would give, because Ohm's law tells us that the current equals the E.M.F. divided by the resistance. The E.M.F. is the same in the large one as in the small one; but the resistance is less, and therefore the current is stronger. So that if you wish to get the same effect from both cells, you must put in the large cell only enough liquid to cover the same amount of surface that you have covered in the small cell. The internal resistance of a battery is the resistance of the plates and the liquids in the cell; it is the resistance between the terminals of the battery.—WATT.

[56648.]—**Bichromate Battery.**—If you arrange your cells for quantity the difference in their size does not matter; but they must be of equal E.M.F. If the E.M.F. is different in the cells, less current will be got than if the weaker cell were off altogether, and a more rapid exhaustion of the stronger cell will ensue. If you arrange for intensity, have the negative elements of equal size. When they are of different sizes the power of the series is reduced to what it would be were all the negative elements the size of the smallest one. Other things being equal, the power of a battery depends on the area of the negative surface. By the electrical resistance of a substance is meant the tendency which the substance has to obstruct the passage of electricity. In a cell the current is limited by the resistance of the fluid, and this (called the internal resistance) is diminished in proportion to the distance between the plates being decreased, and in proportion to their size being increased.—BOBADIL.

[56648.]—**Bichromate Battery.**—The difference in size is of no importance when all the zincs are joined together to form one negative pole and all the carbons for the positive terminal. They are then said to be connected for quantity, or, as it is at present called, "in multiple arc," and act as one large cell. If you connect the cells in series the electromotive force increases with the number of cells, but the resistance of a small cell is greater than that of a large one, and as the same amount of electric action takes place in all parts of the circuit the small cells having the most resistance will grow hot, because the heat developed by galvanic action is in proportion to the resistance. When the small cells become heated the liquid becomes a better conductor, and in consequence a stronger current passes, so that a battery composed of a number of larger and smaller cells will give more current force than the same number of cells the size of the smallest of the series. Much of the electric force, however, is lost in heating the smallest cells when the series is unequal in size, and it is best to have the zinc surface of each element of a battery the same amount; thus a battery with a zinc 2in. square is equal to one with a zinc 4in. by 1in.—J. SUTCLIFFE.

[56650.]—**Lead Burning.**—It is too much to ask our worthy Editor for more space on upright lead burning, as the subject was exhaustively treated upon through the columns of this journal, and if the instruction had been thoroughly carried out the machine must work satisfactorily, as I have scores of letters from young plumbers who have made machines and are delighted with the results. If your machine is made right and you have plenty of zinc in the machine, say 8 to 10lb. of bar zinc, this will give you a surface of at least 3ft. super., and 5 of water to 1 of acid, or, say, 20 pints of water to 4 pints of acid should last you for an hour's good burning, and another pint of acid added after the hour or so's work, should carry you on for another hour; but, of course, you require the very best sulphuric acid, and not such as is generally sold at oilshops, which I have been particular to speak about. Perhaps you have only added 5 pints of water to 1 pint of sulphuric acid to your zinc, and have not sufficient in quantity, or not sufficient zinc, perhaps too little of both. Have you seen Vol. I. of my work, which treats very exhaustively upon the subject? The exhausted acid must on no account be used a second time. The flame being of a yellow cast, at once tells me that you are using it without wind. The sluggishness is owing to the fact that you have no pressure of gas in your machine owing to insufficient quantity of acid and water, or that the area of the zinc is insufficient for the quality of the acid. If "Young Beginner" will make an appointment, I will show him a small machine made exactly as the one I illustrated in the "E. M." which will run on for two hours without further acid or trouble, or I will send him one if he will communicate with me, as I make them.—P. J. DAVIES, 78, Earl's-court-road, Kensington, May 21.

[56651.]—**Boiler.**—This accident, or rather explosion, would, from the information given, appear to be due to the explosion of gas in the flues. After banking up the fires and closing the dampers, each furnace would be a huge gas retort, and the gas, probably (CO) carbon monoxide, would be generated and held in the flues, and immediately the doors were opened it would take up oxygen to form ($CO_2$), carbonic acid gas, and probably become lighted, and thus cause the explosion. Time, place, and extent of damage would be very valuable to me at the present time, as it would probably confirm a strong argument I have recently used, and would no doubt enable me to give "A. S." some reliable information as to how to prevent similar explosions, and I shall be glad if he will publish full particulars or write me direct, which shall have immediate attention and a reply through the post or these columns.—BOSWELL, 6, Cass-street, Salford.

[56651.]—**Boiler.**—There is nothing at all extraordinary in the facts as stated by you. The gas from the banked-up fire had accumulated in the flues during the Sunday, and as soon as the damper was raised on Monday the fire at once began to brighten, and possibly an accidental spark might have fired the gas. In this case, it was no doubt the result of gas forming in some pocket or hollow in the setting not thoroughly swept by the draught. As to a remedy, that is hardly possible to say offhand—except that on breaking up the fire on a future Monday morning I would advise the damper to be opened wide for a few minutes before the fire is knocked about, and drawn forwards, thus sending a volume of air through the flues, which would disperse and dilute the stagnant gas. In a boiler-flue the conditions are very favourable to forming an explosive mixture. At a large Lancashire boiler, where much sawdust was burnt, minor explosions, were frequent; sufficient to reverse the draught for a second, and blow out flame freely on the fireman, if he was in the way. As with coaldust and flourdust in a flourmill, if the particles be in a state of division only fine enough, an explosion is easily producible.—Invicta.

[56652.]—**American Organ.**—If your instrument is an ordinary American organ, containing one row of 8ft. reeds (not 4ft. diapason, as stated in query), the bellows is probably too small to supply sufficient wind for an additional set of reeds and sub-bass. A sub-bass would require extra pressure of air to make the reeds sound properly. My advice to you is this:—If convenient, sell your present instrument, and build one of a size to your liking, and not waste time and money in trying to accomplish what would result in apparent failures. I may add that you can attach a vox humana without much difficulty. That is reasonable enough. The diapason set is of 8ft. pitch, and not 4ft., as you have specified.—G. Fryer.

[56653.]—**Electric Bell.**—The rule which is usually followed in winding electro-magnets is to wind as much wire as will triple the diameter of the core. No. 28 might do with an increase of the battery power mentioned; but it might be safer to use a thicker size—say, 24 or 26—and your two cells will have a better chance, provided they are not too small.—Bobadil.

[56653.]—**Electric Bell.**—You can use No. 28 if you have it by you; but No. 24 is about the size generally used. There is a rule for getting the best effect from a given diameter of iron, which is: Make the diameter of the magnet, when wound, three times the diameter of the iron core, which in your case is ½in., so that your magnets when wound should be 1½in. in diameter. You would require about 2oz. or 3oz. to each leg of the magnet. —Watt.

[56654.]—**Portraiture.**—In the first place, you don't give long enough exposures in the room, and consequently your negatives are under-exposed; that is to say, you get the details of the dress, if a dark one, all right; but you get the faces, which are lighter, too dark in the negative, which makes them print without sufficient detail in the print. In an ordinary room it is almost impossible to take people without special lighting arrangements; it requires at least an hour's exposure to take a decent picture; the inside of a church takes *five hours*, even with quick plates. Out of doors your mistake is just the reverse: you expose too long without the stop; it might be the right exposure with a very small stop, but without a stop it is far too much, unless the lens is extremely slow. You should never take pictures without a stop to begin with: you won't get clear pictures under any circumstances if you do that; generally the smallest stop is not at all too small. Your remark that you get the groups tolerably (Why only "tolerably"?) well, exposing eight to ten seconds with the stop, shows that *that* is somewhere about the right exposure. It is not very easy to get good portraits with a *view* lens; if you had a *portrait* lens, a good many of your difficulties would be removed. I have not tried the "Uranium" plates. I would advise you to try Marion's, which I can answer for, and a perusal of his book would help you enormously.—R. A. R. Bennett, Walton Manor Lodge, Oxford.

[56654.] — **Portraiture.** — As I have gone through the same annoyance as "Camera," I can sympathise with him. To get a good portrait in an ordinary room with a ¼-plate landscape lens he will require to get a sitter possessed of extraordinary steadiness and patience. According to Burton's table of comparative exposures a lens and stop $\left(\frac{f}{64}\right)$ which takes five seconds exposure for an open landscape requires 16 minutes in an ordinary room. I also observe that his ratio between portraits out of doors and in an ordinary room is as 1 to 30; so if "Camera" gets a good portrait out of doors with 30 seconds exposure he will require 15 minutes inside. My own experience, however, is that good portraits cannot be taken with a landscape lens in the house; but, learning that Mr. Armstrong and Mr. Millar had succeeded remarkably well with a portrait lens of 4in. aperture, I procured one and get fine results with 25 seconds exposure, which is the same as given by Mr. Millar to the portrait which took the medal at the late exhibition. "Camera" asks if a near object takes longer to impress itself upon the plate than a more distant one. I answer not in the sense of distance, but because there is a smaller surface throwing in light on the plate. Take the difference between a portrait and a landscape—the one reflects light from, say, 36 square feet of surface, and the other from 3,600 square feet.—B.Sc., Plymouth.

[56655.] — **Cork Frames.** — I should have thought the simple plan of boiling the corks a little while before using would have answered your purpose. Have you tried this?—R. A. R. Bennett.

[56658.]—**Boiler Enamel.**—There are boilers and pans coated inside with white enamel. You will see them at any ironmonger's shop, but you will hardly be able to do them yourself.—Os.

[56659.]—**Cutting Ebonite.**—When turning or working ebonite, in all shops I know of, the ordinary tools for brass are used for ebonite; but a slow speed is used for turning.—Watt.

[56659.]—**Cutting Ebonite.**—It is just possible that your ebonite is adulterated with some hard silicious material, and that takes the edge off the tools. Pure ebonite (vulcanite) should contain little else but rubber and sulphur, and is very easily turned and cut with tools ground as for hard wood turning.—Os.

[56659.]—**Cutting Ebonite.**—If the ebonite were pure—*i.e.*, only made of rubber and sulphur subjected to heat, there would be nothing to take off the edge of the tool; but as it is, ebonite, like vulcanised rubber, is seldom made without the addition of earthy matter to reduce the cost. I heard this many years ago as to the vulcanised rubber trade; but do not know for a fact that it is so with regard to vulcanite or ebonite. Nothing but regrinding or sharpening the tools will do. Just the same as with ebony, you want a harder steel tool, and frequent applications of the stone. In this case (ebony) it is because Nature has sucked up silicious matter into the pores of the wood.—R. S. T.

[56660.]—**Eclipses of Small Hand of 24h. Clock.**—Starting at 24h. or zero, where the fingers are only in conjunction at the exact hour, we find that the minute finger, in overtaking the hour finger between the hours 1 and 2 makes $1\frac{1}{23}$ circuits; therefore the fingers are in conjunction between the hours 1 and 2 at the time of $1\frac{1}{23}$ of the clock; between the hours 2 and 3 the time would be $2\frac{2}{23}$, and so on, gaining $\frac{1}{23}$ each hour round the dial. —J. Jewsbury.

[56661.]—**Bending Iron, Gas, and Steam Tubing.**—Gas barrel can be bent cold in a tyre bender, the same as blacksmiths use for bending wheel tyres, or hot by gently tapping it over the beak of an anvil.—F. Smith.

[56661.]—**Bending Iron Gas Pipe.**—If you are not up to bending the tubes with heat alone, you may easily prevent crippling by filling the tube with dry sand well rammed in, drive into the ends of the pipe a couple of wood plugs to keep the sand in, and at the proper heat you can bend the pipe to any curve you want. Five minutes with a practical man would show you more than pages of letterpress.—Invicta.

[56666.]—**Valve-Gear.**—If your new plan gives an admission of steam equal to 30 per cent. of the stroke, it would be applicable for many purposes. A few years since an engine was invented and brought into notice which had no slide-valve at all, the piston acting as the distributor of steam. Such was "King's Valveless Engine," as it was termed. In that engine I do not think an admission of 30 per cent. was possible. I am, of course, speaking from memory solely, and without reference to any description of the engine. Then, again, we have the "Edwards" engine, which had no slide, the piston controlling the steam entirely, whilst I myself designed an engine which was made by an ingenious Yankee friend for his own use, in which the piston controlled the steam. In that case the steam admission could be made equal to any fraction, or the entire stroke, but was a fixed quantity. In an engine of ordinary construction the steam admission is sufficient for many purposes. But whilst cutting away the slide-valve does your plan give either lead to the admission or the equivalent to inside lap compression? If not, the most essential points have yet to be dealt with for commercial engines. The cut-off of "ordinary" engines may be anything. But a very usual proportion is ⅝, or even half-stroke.—Invicta.

[56667.]—**Drill Chucks.**—If "W. E. F." will get the "Little Giant" chuck, he will find it has all the properties he requires. We have used them for many years for all our lathes and drilling machines, and they are good tools, stand hard, rough usage, and will stick to anything. We have some scroll and other chucks, bought for drilling, but the only one of any practical use is the "Little Giant," of which we have about 30 in constant daily use; any of them will hold a 1in. drill firmly for the heaviest cut the drill will stand. —T. F.

[56668.]—**Powerful Bichromate Battery.**—There is an excellent reason for having plenty of solution, for the zincs do not get exhausted nearly so soon as the solution does, and consequently the more solution there is, the longer the battery will keep working. If you want a strong battery for a short time, use large plates of Zn and C in proportion to the quantity of solution. If you want less power, lasting for a longer time, use smaller plates and more solution.—R. A. R. Bennett.

[56668.]—**Powerful Bichromate Battery.**—An electromotor for a sewing machine cannot do any work with four Fuller's cells. The boat you describe will require six cells of a bichromate battery, having carbon plates not less than 6in. by 3in., and zinc about 5in. by 2in., for which you must use a solution of 2oz. bichromate of soda or potash to each pint of water, then stir it with a glass rod, and add sulphuric acid till the liquid gets warm; pour it into the cells while hot, and have the zincs amalgamated. A Grove's battery will do as well with six cells, platinum 5in. by 2½in., but the nitric acid is unpleasant.—J. Sutcliffe.

[56668.]—**Powerful Bichromate Battery.**—Fuller's cells are not suited for driving electromotors, as the internal resistance is too high. You will get a better result from 4 quart simple bichromate batteries, and by using Trouvé's solution you can make them last three or four hours. If you have room, I should put six cells in, and make the cells as large as possible. You will not get much out of six carbons and four zincs in one cell, as there is too much local action, which only heats up the cell and does no good. You cannot do better than two carbons and one zinc in each cell; if you only want the battery for a short time you can make your cells smaller. As the current depends on the chemical action between the zinc and the liquids in the cell, the amount of liquid required must depend on the time the cell is required to work; this can easily be found out by a few experiments, taking different sized pots and filling them to different heights, and notice how long each cell lasts.—Watt.

[56671.]—**Porous Cells.**—I once cleaned some porous cells by burning them in a clear coke fire. They must be well dried, and gradually heated.—Os.

[56673.]—**Mechanics.**—I think a figure is hardly necessary; but if not quite clear, please construct a triangular pyramid A B C D, and let P Q R S be the forces at A B C and D respectively. Let $x$ = distance of centre from B C D, and let $h$ = distance of A from the same: then we have at once $x\,(P + Q + R + S) = hP$; but P is proportional to $BCD = kBCD$, say, $\therefore x\,(P + Q + R + S) = kh\,.\,BCD = k \times$ volume, and since the volume and $k$ are constant, we see that the centre is equidistant from the three faces, and is, therefore, the centre of the inscribed or one of the escribed spheres. If the forces all act in the same direction, it will be the centre of the inscribed sphere; if not, that of one of the escribed spheres.—Hemisus.

[56675.]—**Lemon Juice.**—Heat the juice to the boiling point and put into the bottles hot; fill them right up to the corks; use good corks, and then dip the ends of the bottles in melted resin; if the air is perfectly excluded the juice will keep all right. You can warm the bottles up first with hot water. —Os.

[56675.]—**Lemon Juice.**—Heat the juice to 150° Fahr., filter it, and set it aside in bottles filled to the brim, and corked and sealed so as to prevent the admission of air. The trade uses what is incorrectly called *liquid* sulphurous acid (properly *solution* of sulphurous anhydride), about half an ounce to a gallon; but it is not quite satisfactory, on account of the slight taste it imparts. Salicylic acid is not open to this objection, but is regarded by some as ineligible on other grounds.—Percy Stanley, 119, Manchester-road, Poplar.

[56675.]—**Lemon Juice.**—Strain the juice through flannel, put into bottles, filled only to the shoulder, and cork tightly with a plug of cotton-wool. Into a pan place a layer of hay or straw, about an inch in thickness, on this place the bottles upright, pour into the pan cold water until the bottles are immersed to a fourth of their height, and put on the lid. Place near a fire until the water becomes hot, then over the fire until the water boils, continue the boiling for half an hour, remove from the fire and allow to cool, but *without removing the lid*. When *quite cold* take out the bottles and with a light burn off the loose filaments and apply hot melted sealing wax, beeswax, or paraffin until the wool is quite covered. If these directions be carefully carried out the juice will be preserved, not only for the summer, but for years.—W. H. Darling, Manchester.

[56676.]—**Free Reeds.**—From the wording of this query it is quite evident that the querist is unable to tune reeds, apart from mechanical assistance. I will, therefore, simply make a few remarks on the subject, which I hope will benefit and help him in the future. The best and proper time to tune harmonium reeds is when the reeds are secured to a pan or soundboard on which the reeds are intended to remain. To tune reeds under the conditions suggested in the query is little better (if any) than useless. If a person desirous of learning the art of tuning has not the ear sufficiently perfect to accomplish the operation without mechanical assistance, he is not very likely to be successful, and if any mechanical assistance is required in making a tempered scale (or laying the bearings, as it is sometimes called) I would suggest a set of 12 tuning forks, chromatically arranged, as a guide for producing the scale for tuning. Let me advise the querist to discard the somewhat foolish ideas expressed in the query.—G. FRYER.

[56677.] — **Boring Small Wood Handles.**—Have a drill chuck fixed on the back centre of the lathe. For tools, use ordinary drills, such as are used for metal. I have tried all sorts of drills for woodwork on the lathe, and find nothing equal to these.—OS.

[56684.]—**Electro Motor.**—To MR. BOTTONE.—Wind it with the same sized wires as recommended in my book—viz., 7lb. of No. 16 on the fields, and ½lb. of No. 20 on the armature. But this dynamo is much too large for a sewing machine motor. To work it properly it would require at least 20 quart bichromate cells. Why not rig up a small motor with F.M.'s of about half the size, which will require only about 3 quart bichromates? Jones, of Lambeth, advertises in this paper sets of motors with wires for 5s., I think.—S. BOTTONE.

[56686.]—**Bending Wood.**—Anyone who could tell you that hard wood can be bent at right angles ought to have been able to tell you how it was done.—OS.

[56687.]—**Wheel Calculations.**—One rev. of B gives 1·46 turn of G. Therefore, to bring the wheels in the same position as they were at starting, we find—

$$1 \times 50 = 50 \text{ rev. of B}$$
$$1{\cdot}46 \times 50 = 73 \text{ rotations of G.}$$

—J. JEWSBURY.

[56687.]—**Wheel Calculation.**—The following formulæ will be a guide to "Sammy" for what he requires. According to his plan in query he wants machine to go slower; so by multiplying the number of teeth in wheel B by the revolutions he makes by the handle, say 40 per minute, then divide the total by wheel C, the product will be the speed of A as required; thus, formulæ: $\frac{23 \times 40}{50}$ = 18·20, ratio of shaft A. This will answer either gaining or losing speeds in your case.—COG-WHEEL.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

Since our last, Glatton has replied to 55879.

**Welding Cast Steel.**—Take rock saltpetre, ½lb., dissolve in ½lb. oil of vitriol, and add it to one gallon of water. After scraping the steel, get it hot and quench in the liquid, and then heat, and it will weld like iron. Better than borax—so it is said.

THE *Steel Age* says that steel rails cut up into lengths of a foot are being successfully melted in foundry cupolas by Mr. R. E. Masters, who has succeeded in producing some very fine castings at a rate of 5lb. of steel to 1lb. of fuel consumed.

## QUERIES.

[56688.]—**Rifle.**—Being about to go to Devonshire for my holiday, and being a member of one of the Mx.R.V.R., should like to take my rifle. Would one of "ours" inform me if the excise officers would interfere with me, if I used a Morris tube for practice only in a field the property of my uncle?—DEVONSHIRE GIRL, ONE OF THE A.P.O.C.

[56689.]—**Battery for Electric Lamps.**—Can anyone tell me how the new batteries for electric lighting are made? I believe that 16 cells will ignite 14 to 16 Swan lamps of 8 to 10 candle power for 12 to 14 hours. I wish for directions as to size of plates and construction of battery, exciting fluids, and cost?—SM.

[56690.]—**Flux for Alumina.**—Will any of our chemical readers kindly inform me what flux can I use to fuse alumina at a heat not much greater than melting cast iron? I am aware that alumina can be fused alone by the oxy-hydrogen blowpipe. Any information on the subject will oblige—EX-GARRISON GUNNER.

[56691.]—**Water Gas.**—We read that our American cousins are trying to produce an incandescent light from water gas, by heating a metallic spiral in the flame. What is this water gas, how is it made, and what gases is it found to contain?—EX-GARRISON GUNNER.

[56692.]—**Carbon in Cast Iron.**—Cast iron, when fused, is found to be capable of taking up an extra quantity of carbon, which is again deposited on the iron cooling. I want to know how much carbon can be thus added to the fused iron, how it is to be done, and what sort of carbon (charcoal, graphite, &c.) should be used? The iron is fused in a crucible by means of a gas-furnace.—EX-GARRISON GUNNER.

[56693.]—**Silos.**—I should feel obliged for any further information on this subject beyond that given in reply to Rob Harris, 55802, No. 1,036. Also respecting the opening for consumption—how long will it keep good after opening? Can it be opened and closed again as required, without damaging remainder? Should this meet the eye of "Day Silo," who replied to "R. H.", Feb. 20, No. 1,039, any information kindly sent to the advertised address would be forwarded to—NEW ZEALAND.

[56694.]—**Butter Kegs.**—Would any of "ours" kindly give instructions how to make these kegs, say, 15in. top and 12in. bottom diameter? Also, what is the best kind of butter worker, and how made?—NEW ZEALAND.

[56695.]—**Block Instrument.**—To MR. STRETTON OR OTHERS.—I am inventing a two-wire block telegraph to meet the requirements of the present system of signaling. Is there any two-wire block now working? If so, where, and could you describe it, as I do not wish to infringe on other patents? What is the tell tale block? Any information will oblige from any correspondent?—ELECTRIC JIM.

[56696.]—**Conductive Glue or Cement.**—I wish to pass an electric current through a series of thin copper plates or diaphragms, temporarily joined together by some kind of glue, cement or varnish, but everything I have tried seems to interrupt the current. Could some of our electrical correspondents suggest some suitable material, not to give great strength, but to resist pretty well the action of the water? I would prefer to apply it to the plates, when wanted, as glue with a brush.—A YOUNG AMATEUR.

[56697.]—**Cutting Glass Bottles.**—I have a number of large glass bottles, with narrow mouths, which would make capital jars for battery and other purposes if I knew a simple and practicable way of cutting off the upper parts. Some time ago a scientific (American) paper gave the following method of doing this. Let the bottle stand in a sufficient depth of cold water on the surface of which floats a small quantity of inflammable oil. On igniting the latter, the heat will cause the glass to crack evenly along the water line. I have tried this with turpentine, but without success. Perhaps some reader of the "E.M." can say if this method is worth anything, and if so, where am I wrong? Any information bearing on the subject will much oblige—SODIUM.

[56698.]—**Quinine Manufacture.**—I wish to attempt this in a small way. Will "Os," or some other of your highly practical correspondents kindly inform me—in view of the explosive nature of mineral oils—how I may safely boil the bark in paraffin oil? I am situated where there is no gas, and the oil I buy for my lamps is in four-gallon tins, called kerosene; but there is nothing on the cans to indicate the nature of their contents, save the American makers' names. On one of them I find the mark "125° oil," whatever that may mean. Is this oil likely to be the same (or an efficient substitute for my purpose) as paraffin, and how could I safely boil it, in fairly large quantities, in an ordinary copper say, and at what distance over charcoal fires, and feel the lives of myself and my assistants free from danger?—D. I. T. B. P. O. V.

[56699.]—**Condensing Engine.**—Will "Invicta," or some other kind reader explain the working of a condensing engine? I am now in charge of a high-pressure horizontal engine, and I have got the offer of a better situation to take charge of a condensing engine? Is it the air pump that a vacuum tells is in good order or what part? Does the vacuum vary according to the h.p. of engine or pressure of steam, and why don't a condensing engine exhaust the steam into the atmosphere like a high-pressure engine, and what is the difference between a surface condensing and any other condenser? If not imposing, and not taking up too much valuable space, I should be very thankful for a sketch of this engine.—ONE WILLING TO LEARN.

[56700.]—**Circumference of Wire Rope.**—What is the circumference of a wire rope, composed of 119 wires, each 3-32 of an inch diameter, the wires supposed to be perfectly laid together without a core?—MECHANIC.

[56701.]—**Pull of Martini-Henry Rifle.**—Will some kind reader inform me the way to ease the pull of the Martini rifle? I have one with a pull of 10lb., and find it very difficult to make good shooting, especially when practising the knee position. As in all competitions we are allowed to shoot with a minimum pull of 6lb., I should be extremely obliged if someone would show the way to get rid of some of the superfluous weight.—INNER.

[56702.]—**Longitude.**—To "F.R.A.S."—I have in my possession, a copy of Sim's "Mathematical Instruments," date 1838, in the appendix to which is a table for finding the longitude by transit of moon culminating stars

$$\text{as } \frac{\text{Diff. Long.}}{\text{Diff. ☽ RA}} = \frac{3600\text{s.}}{\text{Hourly change ☽ R A.}}$$

it might be supposed that the logarithm of the right-hand side of the equation is given in the table. What is actually given, however is

$$\frac{3{,}600}{\text{Hourly change ☽ RA} \times \text{A}}$$

when A is as follows?—

| Hourly change m. | s. | A. |
|---|---|---|
| 1 | 50 | 1·028 |
| 2 | 10 | 1·031 |
| 2 | 10 | 1·034 |

and so on in proportion. Can "A Fellow of the Royal Astronomical Society," give me any clue as to the meaning of this factor? Reference is made to Mr. Riddle in the preface.—H. KING.

[56703.]—**Algebraical Problem.**—Will any of your readers kindly solve the following:—The number of variations of $n$ things $r$ together : the number $r - 1$ together : : 10 : 1, and the corresponding numbers of combinations are as 5 : 3; find $n$ and $r$.—TROPHY.

[56704.]—**Soft Black Carbon.**—I have a large supply of soft black (coal holding) carbon. Could any of your readers inform me if it could be turned into profitable account? Would it make blacking, combined with other ingredients?—NO SIG.

[56705.]—**Potter's Kiln.**—To MR. S. ABLIDGE.—Thanks for your reply. The kiln that I propose to build, is to burn models, busts, thin vases, &c., done in common and also in Parian clay. I should also like to burn, in the same kiln, common red clay, such as is used for making fern cases, rustic ware, and fancy flowerpots.—J. TOWNLEY.

[56706.]—**Microscopical.**—Will some reader kindly furnish me with information respecting use of polariscope? I have the use of a first-class microscope, and am told that the polariscope is one of the principal features. I am only a tyro in this sort of work, so should be obliged if someone would help me, or tell me where to get a good work about it. I have already a small book about it, which simply says it is easily manipulated, and have done all I can to get the colours, but at present to no effect. I have proceeded as follows:—To the bottom of stage where diaphragm slides, I have put one prism; it is mounted in a brass setting, and revolves through tube, having a milled edge to twist it with, and the other prism appears to screw in just above the object-glass; well, on turning the bottom prism, which is the only one that can move under these circumstances, I find the light very much diminished, and sometimes goes out entirely, not because I get my hand in the way of reflecting mirror, because I am careful about that, so cannot help thinking there is something wanting, and if you could help me I should feel obliged.—IGNORANT.

[56707.]—**Electro-plating.**—I am working a brassing solution composed as follows: 2½lb. of American potash in 6gal. of hot water, filter the solution, also dissolve 2½oz. of acetate of copper in strong liquid ammonia, and stir into the first liquid, then add 5oz. sulphate of zinc, stir until dissolved, finally add 2oz. of cyanide of potassium, filter the solution, and work at 100° Fahr., anode brass and currrent stong. Now I am working this, as I believe, quite correctly, right temperature and current strong, as I am using a gallon Bunsen fully charged. All the results I get is—the cathode turns quite black, or not the least action at all, but not the least sign of brass. Perhaps some of my fellow readers may put me right through our weekly paper.—CATHODE.

[56708.]—**Science Questions.**—Will any brother reader answer the following questions?—1. Required the number of sq. mm., sq. cm., and sq. decimètres, contained in the top of a table, measuring 1 mètre by 70 centimètres? 2. The co-efficient of expansion for gases for 1° C. is ·003665? What is the co-efficient for (*a*) F., and (*b*) 1° R.? 3. A balloon containing 1,200cb. mètres of coal gas under a pressure of 770mm. of mercury, ascends until the bar stands at 530mm.? What volume would the gas in the balloon now occupy, supposing none to have escaped? 4. A piece of a certain metal weighs 3·7395grm. in air; 1·5780grm. in $H_2O$; and 2·2896grm. in another liquid. Calculate the sp. gr. of the metal, and of the unknown liquid?—ST. HELENS.

[56709.]—**Lubrication.**—Will any of your correspondents kindly inform me if it is possible to lubricate all the valves and pistons of a compound tandem engine, from one point on the steam pipe between the throttle valve and the high-pressure valve, and if grease will saturate steam, so as to lubricate practically?—W. SYKES.

[56710.]—**Salicylic Acid in Food and Drink.**—Is this easily detected in butter, jam, milk, wine, and beer? Please let me know the process. It is much used now, and is detrimental to the frame, affecting the kidneys. I believe the French government has prohibited its use. PURE FOOD.

[56711.]—**Fulcrum.**—Would any readers of the "E.M." let me know how to find the fulcrum of the following bar?—10in. long, and weighs 4lb., a weight of 6lb. is hung at one end: please show the working how to get the distance from the end so that it will balance.—FULCRUM.

[56712.]—**Shutter.**—To MR. LANCASTER.—Supposing an eccentric attached to the centre of your instantograph shutter, and the elastic wound round it, would it be any quicker than the ordinary one? I saw one made as above by an amateur who contended—1st. That the speed is much quicker. 2nd. That the greater speed is due to the eccentric. 3rd. That it will give the foreground five times the exposure of the sky. The shutter has a square opening over a round one.—DROP SHUTTER.

[56713.]—**Coal versus Coke.**—Can any brother subscriber who has had experience in the use of coal and coke, for steam raising, inform me how coke compares with coal in practice for evaporative power, and if any special arrangements have to be made to secure proper results from the coke?—Asmodeus.

[56714.]—**Heat Absorber.**—Will any of our correspondents give any information regarding the chemical composition of a good heat absorber? If any of our readers are acquainted with the absorber or nonconductor (used by a set of travelling showmen, commonly known as fire-eaters), the describing of the same would doubtless be most valuable, and oblige.—Inquirer.

[56715.]—**Hydraulic Capstans.**—In the goods yards of the L. and N. W. Railway, I have seen a capstan head worked by hydraulic power, and used for hauling and shunting trucks. It could be thrown in and out of work by a pedal actuated by the foot. I should be glad if any of your readers could describe the mechanism, with sketch, if necessary, and say whether ordinary waterworks town pressure is sufficient to work such apparatus.—Asmodeus.

[56716.]—**Hartley's Gas Calorimeter.**—Can any of your readers supply such information as would enable me to construct one? In these days, when so much is being done and attempted, and so many results to be compared, it is necessary to ascertain the thermal power of the gas, and no doubt the information necessary to an intending amateur constructor will be welcome to many besides—Asmodeus.

[56717.]—**Legal.**—A. (deceased) by his will bequeathed to B. a fortune of a considerable amount, but with the restriction that he is not supposed to claim it until arriving at the age of 25 years. At the time of taking out of probate, about two years since, B. received the information that, with the consent of the executors, he cannot be compelled to abide by above, and is desirous to know in what manner to act, in order to regain his property at the usual period, 21 years.—Lexicon.

[56718.]—**Northern Railway of France.**—Wanted the exact distance from Calais (Pier station) to Paris via Boulogne and Amiens.—W. B. P.

[56719.]—**Waterproofing Cloth.**—Can any reader oblige with particulars as under of Belgian system of waterproofing, mentioned on page 576 of Vol. XXXVII.? Are the equal parts to be taken by measure or weight? Should the solutions be made with hot or cold water? Does it mean that articles must be dipped two or three times to make them thoroughly waterproof? About what quantities would be required for each garment (say trousers or summer overcoats)? If the cloth be what is called shrunk, would this treatment be likely to make it shrink again? Particulars would oblige.—E. J. A. B.

[56720.]—**Mirror Painting.**—Can any of "ours" tell me how to make medium for mirror painting? It is claimed for it that it is indispensable to make colours stand cleaning afterwards.—C. A. Palmer.

[56721.]—**Steam Motor.**—To "Invicta."—Some weeks ago you promised to give particulars of a low-pressure steam motor, and I have since been anxiously looking for same, as I should like to make one before next winter, if it is suitable to drive a small dynamo.—C. W.

[56722.]—**Flywheel.**—Will some kind reader give me dimensions and weight of a flywheel for a two-cylinder engine, 4in. stroke by 2in. diameter, running at 350 per minute. boiler pressure being 35lb.? What difference would it make if pressure on boiler were 50lb.—M.

[56723.]—**Chaster's Electro-Motor.**—I am constructing an electro-motor, as described in English Mechanic, Nos. 1,026, 1,027, 1,029, and 1,041 by Mr. J. E. Chaster, but I fail to find in his instructions for winding the wire, "E.M.", No. 1,041, how the armature is wound, and where the ends are connected. Also, does it matter if the saw cut in the commutator is opposite the wire or iron portion of armature? Will Mr. Chaster or others kindly answer this?—A. Hallett.

[56724.]—**Accumulator.**—Can any reader of the "E. M." inform me what size accumulator of the Faure type would be required to light a 5-candle incandescent lamp, stored by means of a small hand dynamo, and how long the accumulator would last? Also, is Faure's cell the best for my purpose?—P. T. H.

[56725.]—**Western Railway of France.**—Wanted the exact distance from Paris (St. Lazare) to Versailles (Rive Droite), and from Paris (Montparnasse) to Versailles (Rive Gauche)?—W. B. P.

[56726.]—**Legal.**—About 28 years ago N—— L—— died at Madras, leaving a considerable sum of money, by will, to his next of kin, and by an advertisement it came to the knowledge of his brother-in-law, who communicated with the London solicitors having charge of the case. When everything appeared completed this brother-in-law died, and Capt. Chas. Handcock, brother to the present Lord Castlemaine, kindly undertook to see after the money for N—— L——'s sister's children, and took the correspondence on the subject with him to London. This gentleman was ordered to rejoin his regiment, and was unfortunately killed shortly after in Madras, tiger hunting, so nothing further was done in the matter of the money. The persons legally entitled to it are very poor, and ask the advice of the Editor or some correspondent how to ascertain whether the money is still to be had?—J. S. D.

[56727.]—**Resistance Coils.**—To Mr. Bottone.—Will you please inform me upon what kind of a bobbin is the G. S. wire wound? A rough sketch would oblige. I intend making a set of above, and should like to start in the right way.—Phono.

[56728.]—**Legal.**—Would Mr. Wetherfield answer the following? I had an agent who collected rent for some cottages 12 months. He paid first three months, but could get nothing more from him except statement showing he owed £13. He will not hand up, but says he cannot pay; he even will not agree to £1 per month. Can I proceed for embezzlement, and how must I commence?—Regulator.

[56729.]—**Clock Winding.**—I am about to add to my business of watchmaking, the branch clock winding by the year. Will some reader, who has experience, say what per year is generally charged? Also, is it according to the number of clocks each party has?—some people have nearly a dozen, others perhaps two. Shall I have to clean them or repair them for same fixed sum, or how? Of course attendance weekly. Any other hints would be acceptable to—Regulator.

[56730.]—**Six's Register Thermometer.**—I have got a Six's thermometer which, in removal, has got both mercury and spirit column broken up and divided. How can I put it in working order?—Them.

[56731.]—**Midland Engines.**—1. Where are the following engines stationed, and to what class do they belong, viz., 1088—1100? 2, How many of the 1700 class are now working, and what is the highest number on the M.R., and where are the 1700's stationed? 3. How many of the 800 class, and where stationed?—Trophy.

[56732.]—**Dyeing Damask Curtains.**—Can any reader kindly inform me how to re-dye some crimson damask curtains that are discoloured by smoke and dirt? What mordant should I dip them in before dipping them into the dye liquor, and can I use Judson's dyes for the purpose, or not?—Charles Cuthbert.

[56733.]—**Problem.**—The hold of a ship is partly full of water, which is uniformly increased by a leak. The vessel is furnished with two pumps worked by A. and B. of whom A. takes three strokes to two of B.'s; but four of B.'s throw out as much water as five of A.'s. Now B. works by himself for the time in which A. alone would have emptied the hold; A. then pumps out the remainder, and the hold is cleared in 13 hours and 20 minutes. Had they worked together the hold would have been emptied in 3 hours and 45 minutes, and A. would have pumped out 100 gallons more than he did. Required the number of gallons of water in the hold at first, and the hourly influx at the leak?—Trophy.

[56734.]—**Testing Butter.**—Would one of your able chemical correspondents kindly state the most reliable method in vogue for testing butter, and also say what is the usual composition of London "cream," or what is sold under that name, and the tests for it? That it is not generally the product of cow's milk is quite evident, if only from its appearance and taste; it can scarcely be made from bullock's brains, as popularly supposed, or their cells would be apparent under the microscope, which they are not, where, besides oil or fat globules, the only feature is an appreciable, but not very large, amount of opalescent amorphous matter.—S.

[56735.]—**Water Gauge.**—Will any correspondent kindly inform me how many cubic feet of water per second will pass through a horizontal slit 27in. long by 4in. deep, when the water stands at 7in. height above the top of the slit? It would also be very useful to me to have the same information for the following heights of water—viz., 8, 10, and 12in.—Manager.

[56736.]—**Partnership Agreement.**—Will someone kindly tell me if a 2s. 6d. stamp is sufficient for an agreement of partnership where the capital is about £500?—Beginner.

[56737.]—**Cutting Indiarubber Discs.**—Can any of the obliging and intelligent readers of "Ours" give me a suggestion? I require to cut out a number of discs of indiarubber, and wish to know how it may be done most speedily and economically. They are to be about 9in. in diameter, and to be cut from web ⅛in. in thickness. If done with a circular knife, what arrangement would be best? What description of table—iron, stone, or wood? What sort of leverage to work the knife? whom I could get to construct the machine? and what would be the probable cost?—Novice.

[56738.]—**Wimshurst Machine.**—To Mr. Wimshurst.—With reference to the 18in. plate machine exhibited by you at the "Inventions," as I am making one of that size, should be greatly obliged if you would tell me how the granulated appearance of the tinfoil sectors is produced, and also the use of the two binding screws on the baseboard, connected together by a piece of wire? Any other useful hints would be thankfully received by—G. Jackson.

**Liquid Glue.**—With any desired quantity of glue, use ordinary whisky, or methylated alcohol instead of water. Break the glue in small fragments and introduce these in a suitable glass vessel, and pour the whisky over them. Cork tightly, and set aside for three or four days, when it will be ready for use, without the necessity of applying heat. Thus prepared, the mixture will keep unaltered for years, and will remain permanently liquid, except in very cold weather, when it may be found necessary to place the bottle in warm water for a little time before using. The vessel in which it is kept must, of course, be kept always tightly corked, to prevent the volatilising of the solvent. A French formula for a liquid glue directs that a solution of 8 ounces of glue be made in ½ pint of water, in the usual way by placing it in a vessel of water until solution is effected. To the solution it is directed that 2½ ounces of strong nitric acid be added, stirring all the while. Effervescence will take place with the evolution of orange nitrous fumes. When all the acid has been added, the liquid is allowed to cool. It should be kept in a well-stoppered bottle, and will remain permanently liquid. It will neither gelatinise nor putrefy, and is said to make a very serviceable cement for various domestic uses, such as repairing cabinet-work china ware, &c. Another formula directs that a jar or bottle be filled with glue broken into small fragments, and the same covered with acetic acid. It should then be placed in a vessel of hot water for several hours until all the glue is dissolved.

## ANSWERS TO CORRESPONDENTS

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, May 27th, and unacknowledged elsewhere:—

J. McG. Ross.—J. A. Josolyne.—A. Kimber.—C. M.—B.—Bon Accord.—R. W., Newcastle-on-Tyne.—Invalide.—F. M. Wetherfield.—T. H. Bury.—Cosmopolitan.—Medicinæ Doctor.—Artibus Magister.—C. E. Stretton.—Student.—S. J. S. L.—Another Millwright's Apprentice.—A Fellow of the Royal Astronomical Society.—Midland.—Canmore.—F. H. Wenham.—Hemisus.—Rob. Crusoe.

### CAUTION.

We regret to have to put our readers on their guard against a swindler who has recently been making use of our Sale Column. We particularly caution readers *not to send money before they get their goods* except by means of a Post-Office Order made payable ten days after date, and to stop the order and get their money back if the goods do not reach them before the ten days expire. We do our best to keep swindlers out of our advertisement columns, but they easily evade us by changing their names and addresses. Especially during the next few weeks we warn readers against "bargains." People who are ready to part with apparently valuable goods at ruinous prices should always be inquired about before money is sent them.

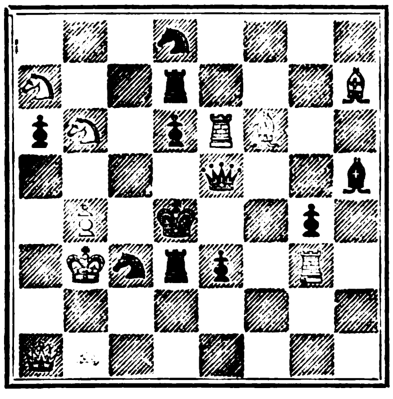
Inquirer. (Yes, amber varnish—to be obtained of any dealer in the best kinds of varnish.)—Picture Frame. (Are you sure a machine is used? A vice is sufficient, and some makers do not even use that.)—Thos. Jackson. (The English Mechanic telephone appeared in the number for August 11, 1876. Number and volume out of print.)—L. (For asthma, see pp. 430, 452, 475, 501, 522, 570, 593, Vol. XXXII.)—Stockport. (The calculus was exhaustively discussed so recently as the last volume. See the index for the references. The best work of an elementary kind is Knox's "Differential Calculus for Beginners" (Macmillan.)—T. Kerr. (The only way is to study the subject of electricity and then attend some such classes as those held at the Finsbury Technical College.)—Ignoramus. (The only way is to apply to firms willing to take apprentices. Fees and terms vary. The best advice is to enter a shop where all sorts of repairs are done, as well as making.)—H. Aston. (There is no book, so far as we know. See the index to Vol. XXXIX. There is a great deal about gas-engines in that volume.)—Desideratum. (Brazing and soldering jewellery fully described in Vol. XXXIII. pp. 22, 44, 70, 119, 170, 264, 334, 455. See also indices generally.)—Trader. (See Hints No. 5. The statement seems to set out the items plainly; but we cannot afford space to print it.)—J. A. Campbell. (We do not remember it. Was its receipt acknowledged?)—F. (You will find a description of the manufacture of macaroni and vermicelli in Payen's "Industrial Chemistry," Longmans.)—Vanduara. (We have no recollection of it, and cannot find it, although we have looked back considerably more than two years. There was a pianoforte hammer, but not a tuning hammer.)—E. M. (See Hints No. 4. Pioneer Paint Co., 5a, Aldermanbury Postern, E.C.)—M. (See indices. The best books are Reed's "Engineer's Handbook," T. Reed and Co., Sunderland, and Ainsley's "Engineer's Manual," T. L. Ainsley, South Shields. 2. For all information about the Whitworth Scholarships see the official manual, to be obtained from the Secretary, Science and Art Department, South Kensington, price 6d.)—A Recent Subscriber. (Such information can be obtained from a patent agent. The query is outside our province.)—D. Jones. (It is simply a little mirror, the position of which is slightly shifted by a lever to give "dots and dashes." See reply on p. 266, or index to Vol. XXIX.)—Metlo. (Scrape off; if the articles will stand it, try heat. 2. We cannot even guess, as you do not say what has been put into the solution. Without an analysis, all that can be said is that it is a mixture.)—G. W. (It ought to keep good time if the cleaner understands his business.)—Birmingham. (Try the wholesale chemists. 2. We could not say without experimenting, but see no reason to imagine it would.)—W. C. (See p. 83, No. 1003. A simple plan with brass is to pickle it in dipping acid containing some iron wire until sufficient zinc is eaten out of the surface to leave it pure copper.)—Albert E. Adlard. (How does such a rail act in hot and also in frosty weather?)—Mizpah. (The only way is to join a class. Try the Working Men's College, Great Ormond-street.)—Londoner. (You appear to know which is the best. The sixth edition was published in 1878. You will find others recommended by referring to indices.)—Charles Mason. (See Hints No. 4. A newsagent will supply you with a list. There are several papers of the kind.)—R. S. T. (It results in the production of pure auric chloride. 2. The silver reduced by the battery is pure. A piece of iron settles with the copper. That question has been frequently answered.)

## CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

PROBLEM DCCCCXLI.—BEWARE OF THE DOG.

*Black.*



*White.* [9+11

**White to play and mate in two moves.**

SOLUTION TO 939.

| *White.* | *Black.* |
|---|---|
| 1. Q-Q 3 | 1. Anything |
| 2. Q or Kt mates. | |

(Five variations.)

### NOTICES TO CORRESPONDENTS.

CORRECT solutions to 939 by V. S. Pochin (easy on account of White's want of scope, though prettily planned; no power wanted), A. A. E. Lecluse (inferior), Rev. W. Anderson (Old Romney), M. F. B., E. Stanley Follwell (Q only having power to move, solution easy), A. W. Orr, S. L. Chivers, F. O'N. H., I. H., Exon (key easy, but some pleasing mates), and H. Culmer; to 938 by Brum (the best that has appeared during tourney), V. S Pochin (obvious at first sight that Q B R must move first), T. L. Robins, and R. A. Bennett; to 940 by E. S., H. Culmer, and Streetgate (quite a gem).

F. O'N. H.—On Monday, first post, week of issue.

GAMES received from T. Bourn.

S. L. CHIVERS.—You have overlooked in 938 if $1.\ \frac{\qquad}{\text{K moves}}$ $2.\ \frac{\text{Kt-K 3 (ch)}}{\text{K moves}}$ $3.\ \frac{\text{Kt-Q B 5}}{\qquad}$ K can take P.

I. H.—Where is the mate if $1.\ \frac{\qquad}{\text{P (K 3)}}$ takes P ?

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924. Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII. XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., bound in cloth, 7s. each. Post free, 7s. 9d.
Vol. XL. now ready, price 7s. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words .. .. .. .. .. .. .. | 2 | 6 |
| Every additional eight words .. .. .. .. | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words .. .. .. .. .. .. | 0 | 3 |
| For every succeeding Eight Words .. .. .. | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words .. .. .. .. .. .. .. | 0 | 6 |
| For every succeeding Eight words .. .. .. | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists, London."—Also makers of Epps's Chocolate Essence

**Holloway's Ointment and Pills.**—Skin diseases scrofula, scurvy. This class of complaints not only affects the individual, but is too frequently transmitted to the offspring. How important, then, under such serious consequences, it becomes thoroughly to eradicate strumous taints from the blood. Holloway's Ointment and Pills uproot all such latent corruptions

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—CAPLATZI, Science Depot, Chenies-street, near British Museum. Established 1862.

What offers for half horse-power **Steam Engine**, nearly new, brass cylinder, lagged in rosewood.—Apply, WILLSON, Coney-hill, Gloucester.

**Perambulator Wheels**, new, ⅝ rubbers, turned axles, complete, plated caps. Exchange Silver Curb Albert. Mutual approval.—W. SMITH, Bilston-road, Wolverhampton.

Wanted, Lever **Watch**; good exchange. Wanted, offers for Youth's Tricycle, Meteor pattern; part finished 2-horse engine bed; 120 "E.M."—As above.

**Interior Background**, on roller. What offers in exchange?—G. FRYER, 9, Portland terrace, Ealing Dean, W.

Tough Mild Weldable **Steel**, 5-16in. to 1in. round, or square. Will take anything useful in exchange.—H. GILBERT, Oxford-road, Sheffield.

Warranted Crucible Cast **Steel**, 7-16in. to 1in. diameter, 1¼ to 3ft. lengths. Will exchange for anything useful.—H. GILBERT, Oxford-road, Sheffield.

Will exchange Singer's **Sewing Machine** (new) and Engineering Books for Tricycle; broken or out of repair no consequence, if repairable.—T. PALMER, Keston, Kent.

Offers wanted for **Digitorium**, cost £3 3s., strong pliant springs; also good Opera Glasses, achromatic and telescopic, six achromatic glasses.—HARDING, 196, Holloway-road.

Exchange offers wanted, in cash or otherwise for ORGUINETTE, cost £2 15s., in perfect order, as new, with music.—HARDING, 196, Holloway-road.

Wanted a quantity of **Chemicals and Apparatus** &c., in exchange for other goods, or cash; must be cheap and immediate.—Address as above.

Last year's "**Electrician,**" clean and in good condition. What offers?—E. ROSS, Regent House, Sydenham.

**Cottage Piano**, Truss Legs, Panel Front. Take Tricycle or Harmonium and £8 cash.—C. SEARLE, Sunninghill.

**Freshwater Filamentous Algæ**, comprising the Zygnemaceæ. Exchanges of mounts or gatherings wanted.—C. PECK, Princes road, Heaton Moor, Stockport.

**Micro.-Photo. Objective**, by Dallmeyer, also other Photo Apparatus, for bound vols. of E. M., or offers.—DAY, 56, Driffield-road, Old Ford, London.

**Speculum**, Silver-on-Glass, good definition, 9 inches diameter, 6ft. 2½in. focus. What offers?—DAY, 56, Driffield-road, Old Ford, London.

**Intensity Coil**, ⅛in. spark, half-pint bottle bichromate battery, incandescent lamp, semi do., and galvanometer. Exchange or offers.—G. R. MILBOURNE, Twyford, Berks.

7 H.-P. Brotherhood Patent **Engine**, also nearly finished 50-light Dynamo. Exchange for Microscope, Tools, or offers.—A. J. SELLS, 158, Mare-street, Hackney, E.

Superior **Lathe Bed**, Standards, Flywheel, and treadle, by Milnes, Bradford, to exchange for Safety or 52in. ordinary Bicycle of good make.—F. UNDERWOOD, Beverley.

**Steering Wheel**, mahogany and brass, with case and standards, complete, suit boat about 30ft. Offers.—A. G., 25, Sussex-street, Winchester.

26in. **Screw Stock**, 4 pairs Dies, 14in. and 26in. Tap Wrenches, 10 Taps, Ratchet Brace, 6 Drills, 1 h.-p. Engine, Boiler. Wanted, Lathe.—99, City-road.

**Induction Coil**, ⅜in. spark, with condenser. Exchange No. 16 new covered wire.—A. PERKS, 43, Coten-end, Warwick.

**Induction Coil**, ½in. spark; for Violin, Mandoline, or offers.—JAMES CAMPBELL, 60, Fisher-street, Glasgow.

I will exchange **Patterns** 6½in. back-geared Lathe (no bed), and Poppett finished from same patterns, for Portrait Lens.—J., 8, Greenfield terrace, Llanelly

Wanted, **Horizontal Boiler**, or one to fit 3ft. boat, in exchange for Model Yacht.—S. ANDREWS, 1, Tavistock-terrace, Upper Holloway, N.

New hand-power radial **Bench Drilling Machine**, takes 3ft. diameter, self-acting variable feed, quick return, instantly changed. Offers invited.—HENRY KILBURN, Bishop Auckland.

**Oscillating Engine**, with cylinder two inches long, also two cylinders, 1in. stroke, bored, and steam ways drilled for slide-valve.—Address below.

**Brass Castings** of Horizontal Slide-valve Engine, inch stroke, cylinder bored, and all parts turned.—Address below.

Splendid **Banjo**, 33in. long, with inlaid fret handle, with two instruction books. What offers in electric apparatus?—J. JACKSON, 136, Trafalgar-road, Burnley.

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—KING, MENDHAM, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—KING, MENDHAM, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—KING, MENDHAM, and Co., Bristol.

**Wimshurst Influence Machine.**—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—KING, MENDHAM, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free—As above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—HEWITT, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—MILLAR, Proprietor.

**Billiards.**—Great success of Thorpe's Patent Automatic Cue Tips. Cannot fly off. Cues retipped instantly.

**Billiards.**—Excellent testimonials from Roberts, jun. champion, and other professionals. £5 per week easily earned.

**Billiards.**—District Agents wanted. Send 9 stamps for particulars and sample cue end fitted with patent.

**Billiards.**—Five Shillings for sample cue, also fitted, and 3 extra tips. Thousands already in use.

**Billiards.**—Apply to sole representative for United Kingdom.—A. W. MORGAN, Lancaster Avenue, Fennel-street, Manchester.

Hard **Vulcanised Fibre** for Magnet Heads.—MOSSES and MITCHELL, 68a, Chiswell-street, London, E.C

Hard **Vulcanised Fibre** for all kinds of insulation.—MOSSES and MITCHELL, 68a, Chiswell-street, London, E.C.

**International Inventions Exhibition**, East Avenue, Group 21, Stand 1683.—MOSSES and MITCHELL, 68a, Chiswell-street, London, E.C.

Tudsbury and Sons' "High Tension" **Wimshurst** MACHINES, with Compound Ebonite Plates. List, one stamp.—Edwinstowe, Newark.

24 **Microscopic Slides**, in box, very cheap. List sent for stamp.—WELL, Dalmain-road, Forest Hill.

**Tricycle Wheels**, Bicycle Wheels, and Fittings Wonderfully cheap. Also for Safety Bicycles.—W. GWINNETT and Co., Wolverhampton.

**Lathes**, Lathes! Cheapest and best. List, 2 stamps Nothing equal at price.—ROBINSON, Somerset-road, Sheffield.

100 **Foreign Stamps**, including Brunswick, Ceylon Tasmania, Egypt, Greece, Luxemburg, free 7d.—HELY, Foley-street, London.

**Tricycle House**, full size, portable, hold two bicycles, £5 10s., carriage paid.—X., 7, Clarence-street, Liverpool.

A few Gramme **Dynamos** for sale, cheap.—WALKER and OLLIVER, 195, Severn-road, Cardiff.

**Electro-Motors** from 25s. No dead point. Battery equal Bunsen's. No fumes.—WALKER and OLLIVER.

Leclanché **Cells**, Manganese, Sal-ammoniac, Bichromate Bells, Wire, Pushes. Wholesale and retail.—WALKER and OLLIVER.

**Dynamos** repaired or rewound. Advice given. Competent men sent to all parts.—WALKER and OLLIVER.

Send for **List** of Switches, Indicators, Telegraph Instruments, Parts, &c., for sale, cheap.—WALKER and OLLIVER.

**The Kinetic Engineering Company**, 36 and 37, Brooke-street, Holborn, London. Circulars and list post free

**Dynamo Wire**, 1s. 2d. per lb. Line Wire, 29s. 6d. per mile. Pushes, 4s. per dozen.—KINETIC COMPANY.

**Leclanche Cells**, best. No. 1, 16s.; No. 2, 19s.; No. 3, 22s. 6d. per dozen.—KINETIC COMPANY.

**Electric Bells.**—Best quality, workmanship, appearance and value in market, 40s. per dozen.—KINETIC ENGINEERING COMPANY.

**Maiche Patent Battery.**—Best yet produced. Circulars and Scientific Reports post free.—KINETIC ENGINEERING COMPANY.

**Electrical Supplies.** Wholesale only.—KINETIC ENGINEERING COMPANY, 36 and 37, Brooke-street, Holborn, London, E.C.

**Devonshire Cream**, delicious, by improved centrifugal process. Parcels Post, lb., 1s. 6d.—G. BULL, Manor Farm, Martock, Somerset.

**Microscopes** (Binocular and other). All kinds of Apparatus. Double, Triple, and Quadruple Nosepieces to the trade. Stamp for list.—R. G. MASON, from J. Swift, 24, Park-road, Clapham, London, S.W.

Model **Boilers** of copper. Low prices. All sorts. Send requirements for price.—MONTGOMERY, Stanners-street, Greenock.

Gravet's **Slide Rule**, recommended by H.M. Government officials. Write for prices and testimonials.—Sole Agent, FARRAR, Benson's-buildings, Leeds.

**Microscopic.**—Well mounted Slides, 6d. each; 5s. doz. List and sample, 7 stamps.—TURNELL, Victoria Pharmacy, Southsea.

**Chemical Apparatus.** — Catalogue, 90pp., 500 illustrations, posted 2d.—W. HUME, Lothian street, Edinburgh.

**Photographic Apparatus and Chemicals** for professionals and amateurs. See new illustrated catalogue, post free.—HUME, Lothian-street, Edinburgh.

Brazilian Pebble **Spectacle Glasses**, rough slabs or polished.—RICHARD BAKER and Co., 9, Mincing-lane, London.

Brazilian **Pebbles and Crystals.**—RICHARD BAKER and Co., 9, Mincing-lane, London.

**Mica**, otherwise Talc.—RICHARD BAKER & CO., 9, Mincing-lane, London.

**Planing**, not exceeding 10in. by 10in. by 8in.—B. W CLEGG, 18, Belinda-street, Hunslet, Leeds.

For **Model Work** (wheel-cutting in brass only); also Boring, Turning, and Screw-Cutting.—CLEGG, as above.

The **New Saw**, to work by hand or foot, which so many cannot believe, will cut 3ft. 8in. of inch wood after you take foot off treadle. Will be shown at Stand 437, Inventions.—BRITANNIA Co., Patentees.

**Sliding Mandrel Lathes** for cutting screws in wood or metal. We are about making a 5ft., 5in. centre, price £16. If orders for twelve lathes lower prices can be taken —BRITANNIA COMPANY, 99, Fenchurch-street, London. All letters to Colchester.

**To Ornamental Turners.**—We offer Ornamental Drill Spindle 30s. Drills, 1s. each.—BRITANNIA Co, Colchester.

**Eccentric Cutter Frame.** £2 10s. Cutters, 1s. each. Ornamental Tool Cutter, 15s. Tools for same, 1s. 6d. each.

**Easy Terms of Payment** to those who can give first-class reference.—BRITANNIA Co.

Second-hand **Lathes and Slide-Rests.** Send one stamp for list; six stamps for list of lathes and parts, rough and finished.—BRITANNIA Co.

**Notice!**—BRITANNIA Co. exhibit in Section 4, Stand 437, Middle Court. See plan. As you enter proceed to extreme end of Middle Court.

**Inventions Exhibition.**—We exhibit small Hot-air Motors, suitable for punkahs, fret-saws, pumps, saws, and sewing machines, price £9. Cost per day 1½d. Larger size, suitable for small lathe, £27 10s.—BRITANNIA COMPANY, Colchester.

**French Polishing**, Staining, Painting, and Varnishing. 122 Recipes or Trade Secrets, with full instructions and details, post free, 1s.—I. TOMLIN, 28, Highfield-terrace, Barnsley, Yorkshire.

**Castings.**—Half horse-power Horizontal, Vertical, or Launch Engine Castings, complete, with brass work and forgings, 12s 6d. One horse-power, 25s.—TOMLIN, Highfield-terrace, Barnsley, Yorkshire.

**Castings.**—Bench Drilling Machine Castings, complete, 3s. 6d.—I. TOMLIN, Highfield-terrace, Barnsley, Yorkshire.

**Castings.**—All Brass Engine Castings, horizontal or vertical, suitable for model work, 2s. 6d. set.

**New Designs and Price List** of Perfected Engines and Castings, post free.—I. TOMLIN, Engineer, 28, Highfield-terrace, Barnsley, Yorkshire.

Universal **Cutter Frame**, slides 3in., price £2. Castings, 4s. 6d.—Particulars, address, WM. ALLSOP, Derby-road, Belper.

**Bottles for Chemists**, Wine and Beer Merchants, sample tubes, cases, and boxes.—EDWARD W. DAUBY, Hull.

**Optical Glass** of finest quality, crown and flint; all sizes in stock to 14 inches diameter, discs and sheet —BUCKINGHAM, Blenheim-grove, Peckham.

Cotton-covered **Wire**, D.C. 10 to 18, 1s. 9d.; 20, 22, 24, 26, at 2s., 2s. 3d., 2s. 6d., and 3s. per lb.—C DARVILL, 8, Brent View-road, The Hyde, London, N.W.

Celebrated Kerry **Ferns.** 12 varieties, including Tunbridge filmy, 1s. 5d. free.—FITZPERT, Rathanny, Tralee, Kerry.

Fine 3¼ **Astro. Telescope**, by Wray, £13; excellent definition. Tests given.—T. CLAPHAM, Austwick Hall, Lancashire.

Pumphrey's **Pocket Tripod**, for cyclists, professional and amateur photographers. Perfectly rigid. May be had on approval. Illustrations and testimonials free.—PUMPHREY, Stanhope-street, Birmingham.

Pumphrey's **Hydrostatic Shutter** for instantaneous and timed exposures. Photographs done with it. Free, price 10s.

Pumphrey's **Camera and Lantern**, with 54 illustrations. 2 instantaneous photographs. Full instructions, 2d. post.

Eighty sets **Lantern Photographs** at reduced price. Illustrations of 20 sets post free.—PUMPHREY, Stanhope-street, Birmingham.

**Engine**, vertical, 2½-horse, £6. Marine Boiler, 3-horse, £7.—79, Dudley-road, West Bromwich.

Model **Steam Engine**, warranted to work, 9d. post free 1s.—GEO. HAILEY, Novelty Stores, Seaforth, Liverpool.

**Lessons in Glass-Blowing**, Physical Apparatus repaired. Sprengel and other Pumps to order.—NEWBOLD, 25, Calthorpe-street, London.

**Launch Engines**, Boilers, Propellers, Lathes, and all kinds of Machinery at reduced prices.—S. SMITH, 11, West-street, Soho, W.C.

**Locomotive Photographs**, N. B. Ry., C. Ry., L. and S. W. Ry.; all railways. Carte and specimen, 5 stamps free.—F. MOORE, 1, Naas road, Wood Green, N.

**Engine**, horizontal double oscillating cylinders, ½-horse, price £6, little used.—JOURNET, 194, Great Portland-street.

**Insulated Wire**, best quality only. Price list free. —MAW, removed to 53, St. James's, Brixton, London, S.W.

**Spring Steel**, any size or length, from 1⅛ by 3-16, 8s. 6d. per cwt.—H. GILBERT, Oxford-road, Sheffield.

Field's Society of Arts Student's **Microscope**, 1½, 1, and ¼in. objectives, polariscope and mechanical stage, complete in mahogany case, with accessories, £4.—J. W. LATHAM, Chemist, Romford.

Large **Achromatic Telescope**, cost £10, 3 inch Object-glasses, extra eyepiece. Want Gold Watch or Tricycle, or Gold Guard.—192, Salisbury-road, Everton, Liverpool.

**Launch Engines**, 3½in. by 5in. Vertical, Boiler, 4½ft. by 3ft., shafts, propellers, &c—MIDDLETON 16, Hope-street, Glasgow.

**Launch Engines** for sale, double and single; 5in. and other sizes —JOHN MIDDLETON, 16, Hope-street, Glasgow.

**Launch Engines**, 6in. by 8in. cylinder, link motion and pump, new, £23.—JOHN MIDDLETON, 16, Hope-street, Glasgow.

**Launch Engine** 3in. by 4in. cylinder, has link motion reversing gear, new.—JOHN MIDDLETON, 16, Hope-street, Glasgow.

55s. American **Orguinette**, 30s.; plays any tune; large selection Perforated Paper.—SMITH, 26, George-street, Plymouth.

**Consult Stanley on Everything.**—119, Manchester-road, Poplar. Revised terms last week's column.—See below (special).

**Marvellous, but True.**—Superb Black Ink, 1d. per quart. Recipe, 7 stamps (returned if disappointed).—STANLEY.

**Harmonium**, £4, walnut, full compass, rich tone, quite new, perfect, warranted. -W., 140, Carlton-road, Kentish Town.

Valuable **Patent**, connected with railways, for sale, full particulars from J. T. LEIGHTON, 18, Montgomery-street, Edinburgh.

Steam Engine **Indicator** for sale, cheap, in excellent condition.—J. WILSON, Brookside Villas, Grange-street, Hull.

25 c.-p. **Dynamo Castings**, 5s.; also other articles for sale.—A., 22, Leathwaite-road, Clapham Common.

Fine old **Violin**, with bow, in case, 15s., carriage paid. —A., 22, Leathwaite-road, Clapham Common.

**Lathe Tool Holders**, from 3s.; Tools for do., ready for use, 4d. each.—S. BEECHAM, Mareham-le-Fen, Boston.

**Hand Drilling Machine**, drill ¾ holes, 6in. from edge, from 25s.—S. BEECHAM, Mareham-le-Fen, Boston.

**Brass Cylinders**, accurately turned and beautifully finished, with slide-valve, 16 screws, &c., fitted complete materials and workmanship guaranteed very best, and can be had on approval by deposit. 1in. stroke, 6s. 9d.; 1½, 7s. 9d; 2in., 10s. 6d.—H. F. LOVEGROVE, Optical Works, High-street, Slough.

**Strange Fact.**—Although the cylinders (as above) have been sent on approval to various parts of the kingdom, yet up to this date (May 20th, 1885) not one has been returned.

**Dynamo Castings**, 20 candle-power, 5s., Photo. 6d., Wire, 18s. 6d. Gunmetal Wheel, 4s. Motors, &c.

**Turning, Drilling, &c.**, every kind of work done- —STAUNCH and BUTTERWORTH, 1, Elmfield-road, Bromley, Kent.

**Showcases for Exhibitions**, Models, Scientific Instruments, Nests of Drawers, &c., &c.—FRY and Co., Shopfitters, 90, Borough-road, London.

**Homœopathy.**—Laurie's "Epitome of Homœopathy," 540 pages, together with solid morocco case, containing 44 medicines, complete, price £1.—T. C. F., 332, Strand, W.C.

**Motor Castings.**—Set complete, Field Magnets, Maltese Cross Armature, Brass Bearings, unfinished, 8s.—C. MACCARTHY, Queen's Buildings, Belfast.

**Motor Castings.**—As above, finished, drilled, and tapped ready for winding, 5s. 6d.; wound, 18s. 6d.—C. MACCARTHY.

**Bell Sundries.**—For large bells, frames, cores, posts, gongs, cases, &c., very cheap.—Manufacturer, MACCARTHY.

**Electric Bells.**—Best make, teak and mahogany cases, thick platinum contacts, gong, 4in., 9s. 6d.; 5in., 14s.; 6in., 18s.

**Dynamo Castings.** — For further particulars apply to the manufacturer, C. MACCARTHY, Queen's Buildings, Royal Avenue, Belfast.

**Printing Presses**, from 10s. to 50s., complete numerous testimonials.—Manufacturers, ADAMS BROS, Daventry.

"**American Brand**" Dry Plates, "Ultra-Rapid" and "Salamander" (registered); combine all the best qualities of other makes.

"**American Brand**" give superb results in hands of either professionals or amateurs. Success certain. Try them.

"**American Brand**" for Potash or Ammonia. No trouble about postage. Sent paid on receipt of price.

"**American Brand.**"—Prices: quarter, 2s.; half, 4s. 6d.; whole, 8s.; 4 by 5, 3s.; 5 by 8, 6s.; 8 by 10, 12s. dozen.

"**American Brand**" Dry Plates, only carriage paid from J. W. HUNTER and Co., Stockton-on-Tees.

**Disintegrator** (patent) by Wilson, Exeter, cost £4, price, for cash, £3.—WM. HUNTER, Albert-place, Stockton.

A few **Accumulators**, of 35 ampère-hours capacity, delivery, 6 ampères, 2 volts, well formed, 10s. 6d. each.—SECONDARY, 96, Brompton-road, S.W.

**Patterns**, for 6 inch engineer's screw-cutting self-acting lathe, good, nearly complete set, very cheap.—F. R. DAVIS, East Tytherley Works, Stockbridge, Hants.

**Special Tool Steel.**—We have extra quality of Steel, uniform quality—round, hexagon, flat, 9d. per lb.; parcel post, 3d. extra.—BRITANNIA Co., Colchester.

**Whitworth Lathes**, 6 feet screw cutting, with 40 chucks, £50. Tongue 4ft. back-gear Gap Lathe, with ball chuck, &c., £11, good condition. List of second-hand Lathes, &c., 1d.; ditto of new Lathes and Parts, 6d.—BRITANNIA Co.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. JONES.

**Dynamo Castings**, Jones's patent H: 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s.; 70, 16s. a set.—H. JONES.

**Dynamos**, finished: 8 c.-p., 30s.; 16, 36s.; 20, 40s.; 30, 50s.; 70, 100s. each.—H. JONES.

**Dynamos** for house lighting. — Jones's Patent Laminated Fields and Armatures, 5, 6, and 7 lights, £6, £7, and £8 each.—H. JONES.

**Dynamo Machines Repaired.** Motors, with wire, 5s. 6d.—H. JONES, 48, High-street, Lambeth, S.E.

**Coca Leaves.**—You require nothing but these at Whitsuntide. No necessity to carry heavy luncheon bags.—MARKS and Co., 17, Newcastle-street, Farringdon-street, E.C.

**Coca Leaves.**—The Bolivian Consul-General has sent a splendid testimonial this week in favour of their stimulating properties.

**Coca or Cuca Leaves.**—Many M.P.'s and Clergymen take them constantly. To Cyclists they are a positive necessity.

Persons afflicted with **Indigestion** should chew Coca instead of eating a hearty dinner, and they would soon be cured.

**Coca Leaves.** — Sample packet, with medical and scientific opinions, 13 stamps.—MARKS and Co., 17, Newcastle-street, Farringdon-street, E.C.

**Lathe** for sale, 4½in. screw-cutting gap bed, nearly new. Cost £35, with handy lot of chucks and tools, stocks, dies, and taps, grindstone, with treadle, strong useful bench, with six draws, joiner's vice, and steel screw, bench and leg vice, capital lot of carpenter's tools, and sundries. Suit gentleman amateur.—Call, 123, High-street, Stoke Newington. No dealers.

**Standard Ohms.**—S. BOTTONE has a few of these on hand. Price 2s. 6d.

**Bridge**, Galvanometer, and 8 Coils, up to 200 ohms, complete, in one set. Price £1 10s.

**Wheatstone's Bridges**, 5s. each, post free.—S. BOTTONE, The Limes, Stanley-road, Carshalton.

Several good **Dynamos**, for hand or power.—Full particulars, letter, WARNE, 33, St. John-street-road, E C.

**Microscopic Objectives.**—A 2in., 1in., ½in., 4-10th ⅛th, English Lenses, cheap.—E. S., 105, Myddleton-road, Hornsey

**Uranotype Paper**, 6d. sheet. List free.—HUMPHRIES, Photographer, 44, Cornwallis-road, Holloway, London, N.

Model **Engine Castings.**—Best and cheapest. See list (stamp) and compare.—WOOD, Dalley-street, Broughton, Manchester.

Inch spark **Coil**, discharging pillars, commutator, condenser, 38s., bargain.—J., South-cottage, Thurlow Park-road, Dulwich.

**Incandescent Lamp** in Gilt Scarf Pin, 20 stamps. Trade supplied.—NEW, 24, Dean-street, Soho.

**Incandescent Lamp**, 8d. post free. Only a few left. Trade supplied.—NEW, 24, Dean-street, Soho.

**Incandescent Lamp**, Battery, Wire, Chemicals, Instructions, &c. 2s. 6d. free. Trade supplied.—NEW, 24, Dean-street, Soho.

**Refractors and Reflectors** for sale, a 4⅜in. Cooke (old Thomas), Equatorial.—G. CALVER, Widford, Chelmsford.

**Printing.**—100 Bill Heads, 1s. 3d.; 100 Business Cards, 1s. Larger quantities, special quotations.—BROOKS and Co., Rotherham.

Steel **Name Stamps**, 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d. per post.—R. F. BALDWIN, Robinswood-hill, Gloucester.

2in. **Shafting**, 6ft.; 2 Iron Riggers, 40s.; set 1 H.-P. Governors and Valve, 25s.—99, City-road.

Also **Microscopic Stand Condenser**, 6s. Polariscope, 17s. ½in. Objective, 20s. ¼in. ditto, 10s. Spot Lens, 8s. 6d.

Half-horse **Gas Engine** (Turner patent), warranted perfect.—RESIDE, Brighouse, Yorks.

**Study Chiromancy.**—Chart of the hand, with full explanation, 7d.—H. DYKE, 21, North-street, Taunton.

Amateur and Dentist's **Gas Engine.** Complete Castings, 42s. Drawing, 5s. Litho, 3 stamps.—A. DORRINGTON, West Gorton, Manchester.

Half horse-power horizontal **Engine Castings**, 12s. 6d. None to equal them at the price. Drawing, 18 stamps.—A. DORRINGTON, West Gorton, Manchester.

**Drilling Machine**, self-acting feed motion. Castings, 7s. 6d. Forgings, 5s. Drawing, 18 stamps.—A. DORRINGTON West Gorton, Manchester.

**Engine Castings and Drawings** from a model up to 20 H.-P. List, 1 stamp.—A. DORRINGTON, West Gorton, Manchester.

**Dorrington's Castings.**—Glasgow Agents: J Newall and Co., 473, St. Vincent-street, Glasgow.

**G. W. R. Express Passenger Engine**, scale 1in. to 1ft. Complete set of Castings and Forgings for making same. The cylinders are beautifully bored and faced. Also set of full-sized Working Drawings. Cost £8 11s. Will sell for £5. —Apply, BETA, 7, Paternoster square, London, where model can be seen.

**Universal Trade** and Amateur Supply.—Lecture requisites; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—CAPLATZI.

**Specialities.**—Spark Coils, Batteries, Electric Motors Working Pumps, Lathes, Saws, Hammers, Wheels of Life Vacuum Tubes, Cannons, Fusees.

**Important.**—Parts, Fittings, Prepared Materials for Construction, Matching, Completing, Altering all kinds of Scientific Instruments, Collections, &c.

**Electric Machine**, Coil, Dynamo, Magic Lantern, Telescope, Spectroscope, and Lathe Makers will find thousand requisites uncommonly cheap.

**Electric Machines.**—Largest stock of complete and Parts, Cylinders, Plates, Conductors, Stands, Glass, Vulcanite, Balls, Jars, 100 accessories and experiments.

**Chemical and Medicine Chests**, Glass, Porcelain, Platinum, Copper Vessels, Blowpipes, Bellows, Furnaces, Fireworks, and Apparatus, all kinds.

**Magic Lanterns**, Slides, Microscopes, Kaleidoscopes, Oil and Lime Burners, Retorts, Bags, Bottles, Condensers, Lamp Reflectors, Lantern Bodies.

**Slides.**—Superior, painted, comic effects, and Scientific, great selection. Skilled exhibitors for town and the provinces, very moderate.

**Astronomy.**—Telescopes, O.G.'s, E.p.'s, Finders, Stands, Tubing, Celestial, Globes, Books, Star Maps, Lamps, Micrometers, and numerous other aids.

**Prisms**, Nicols, right angle, Spectroscope, Camera Lucida, Obscura, Bisulphide. Achromatising, Cylindrical Lenses. Polarising Plates, various.

**Microscopes** by Ross, Powell, Beck, Cary, West, Crouch Condensers, Powers, Fine Objects. Prices unapproached.

**Microscopes**, Accessories, Powers, Eyepieces, Condensers, Prisms, Stands, Section Cutters, Cases, Objects. Unequalled in cheapness anywhere.

**Blowpipes**, Glass-blowing Tables, Oxyhydrogen, Spirit, Gas, Black's, B Chests, Copper Condensers, Anvils, Hammers, &c. Minerals.

**Photography.**—Large Stores of Cheap Apparatus. Lenses, Stands, Dishes, Frames, Dark Slides, Bellows, Instantographs, Accessories, Focussing Glasses.

**Conversaziones**, Evening Parties.—Models, Collections, brilliant experiments of all kinds on hire.—CAPLATZI.

**Pumps.**—Air, Steam, Hydraulic, Force, Lift, Mercurial, Experimental, Manufacturing, Hydraulic Gauges, Reservoirs, Accessories. All kinds.

**Cheap Lathes**—Several small Foot-power, also large, Heads, Slide-Rests, Chucks, Cutters. Wheels and Tools, Accessories, Stones, Emery, Diamond Wheels.

**Clock Movements**, Gearings, Cog Wheels, Models, Graduating, Finest Gauges, Meteorological, Seismographical Instruments made and repaired.

**Machines.**—Micrometer Ruling, £4; Engraver's, £3. Dividing Micrometers, Polarimeters, Diffractions, Gratings, Magnetometers, Rain Gauges, various, cheap.

**Electric Bell Fitting.**—Every requisite, new, second-hand. Reliable goods at unapproached prices. Telegraphs, Phonographs. Telephone materials. Instructions.

**Medical Electricity** for rich and poor. Portable, Stationary, Research Apparatus, Books in four languages, Inventions Perfected. Half usual prices.

Catalogue, 2d. **Caplatzi**, Science Depot, Hire and Exchange, Chenies-street, Tottenham-court-road. See 15 years' advertisements.

# ON FIXING AND SETTING DIAMONDS FOR CUTTING AND OTHER TOOLS.

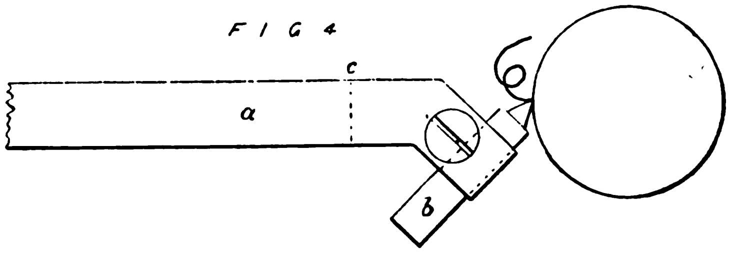
By F. H. Wenham.

ABOUT forty years ago I purchased from a respectable tool shop a piece of diamond, set apparently quite securely in a steel holder with handle, and which was sold for a turning tool or graver for re-touching hard steel engraver's plates. This tool, unfortunately, soon came to grief. I required it for turning glass; but after a few hours' use out came the diamond, and, after a long search down on all-fours, I did not succeed in finding it. I then looked to the way in which it had been set. A piece of steel wire had been drilled up with a hole large enough to admit the fragment; a side hole had been made below the stone as a vent, for preventing it from being driven out by the silver solder and borax used for the purpose of soldering it in place. The thin edge of the socket, or hole in the steel, had been compressed so as slightly to grip the diamond; but a microscope examination showed that the solder had avoided and failed to reach the diamond (for which, of course, it had no affinity), and this had been imbedded only in the hardened borax flux. After this costly bit of experience, I determined not to let such an accident occur again; and as circumstances in the way of business afterwards required me frequently to make use of diamond tools for various purposes, I in future always set them with my own hands. I have mounted numbers without any failure.

First reverting to the usual practice. Non-utilitarian or vanity jewels are set by placing them in a cavity to fit, and drawing and burnishing the metal partly over them. Glaziers' diamonds are set much in the same way; but as these are not for display, the stones may be nearly covered up by the overlapping metal. Having selected the most suitable edge of the natural crystal, and considered its best outward position, a shallow hole is drilled in the end of a stout piece of soft brass wire, and then, by means of small chisels and gravers, the hole is scooped out to fit the diamond. This is then pressed tightly down in its bed, and by means of small drifts and punches the metal above is overlapped and driven down, filing off all exterior surplus during the operation; enough of the wire containing the set diamond is now cut off and filed a little taper, so as to be driven tight into the hole in the swivel-block. I have seen large pieces of black diamond or carbonado mounted in this manner in the ends of soft steel rods ½in. in diameter; to do it well requires much care and patience.

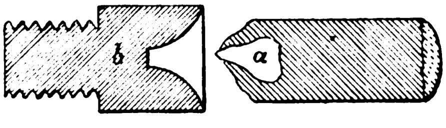
In Young's machine, for redressing or "cracking" the face of millstones, the pieces of "carbonado" of any size were held as follows: On the cutter spindle (which rotated with great velocity) was fixed a stout copper flange with a deep socket. Another similar flange was advanced against this by means of a nut screwing on to the spindle. The diamond was placed between the two flanges with one of its corners projecting just beyond the peripheries, and gripped very securely by screwing them together. The diamond getting partly imbedded in the soft copper the furrows were driven in the millstone by a rotary percussive action, and it would be as well to tighten up the flanges after working a short time, to insure a permanent grip.

FIG 4



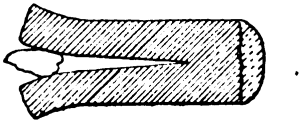
The method I adopted for setting diamonds for turning tools in a speedy and secure manner without using the blowpipe flame and solder is shown by Fig. 1; *a* is the piece of diamond placed in a shallow hole drilled in the end of a copper, soft brass, or steel wire; *b* is a hardened steel plug having a bell-shaped socket; if this is rotated rapidly in the lathe, and the end of wire containing the diamond pressed hard into it by means of the dead centre, with a drop of oil, of course holding the wire so as not to turn, the metal will be compressed and burnished round so as to embrace all the irregularities of the diamond, which at length, if the spinning is continued long enough, will become completely buried, particularly if the centre is withdrawn and the wire oscillated by hand pressure for a sort time in the hard steel socket. In this case a touch on the grindstone will lay bare the end of the diamond ready for use.

FIG. 1.



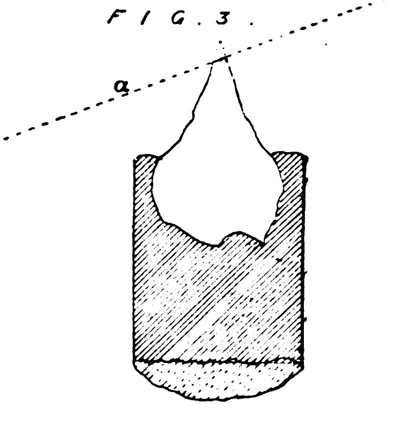
For very small fragments of diamond the soldering process is the most expeditious and easy, and, if managed properly, is perfectly secure. I have some doubts whether large diamonds or fragments about the size of a peppercorn would stand the sudden application of the heat of the blowpipe flame without the risk of cracking. I have been informed by a friend who has visited the Cape diggings, that these diamonds often crack spontaneously from the warmth of the pocket soon after removal from their native bed, thus sometimes reducing them to one-tenth of their former value. In order to avoid this risk, the diggers keep their largest diamonds in a bottle of oil, and suck them dry before showing them to a purchaser; but small diamonds and fragments do not split, nor is their quality or hardness in any way impaired by an ordinary blowpipe heat, and I always prefer to fix them by soldering, as it takes but a few minutes to do. I take a piece of stout copper wire from ⅛in., more or less, in diameter, according to sample of fragment; with a fine saw I split the end of this wire, and open it out in the way shown by Fig. 2. The fragment of diamond, with its selected edge outwards, is then placed in the fork of the wire, and the prongs are squeezed hard together with pliers, and the diamond is thus imbedded in the soft copper; the wire must be gripped and twisted round in various directions, so as to burnish and close up the slit. This is then united by a fragment of silver solder and borax, using the ordinary blowpipe flame; the piece of wire is now screwed into a handle and the surplus copper at the end trimmed off on the grindstone, so that the diamond may project sufficiently for use. This method is the most expeditious, and answers well for light glass-turning, such as trueing up small lenses, which is but a scraping process; but the copper is so soft that with heavy work it is apt to bend, unless the end containing the diamond is cut short off and driven tight into a drilled steel socket or holder; this makes but a clumsy tool.

FIG. 2.



A better way of mounting in an unyielding holder of steel is as follows: Fold a strip of platinum foil tight round the diamond, pressing it down in every part, or else wind close a fine platinum wire over it in all directions. Now drill and broach out a hole in the end of a steel wire thick enough to contain the wrapped stone, to be pressed in tightly, bearing in mind the end of the stone that is to be outwards. If the silver solder is now run in, it will entirely fill the space between the bore of the socket and the platinum casing of the diamond, which will be held as securely as possible; but, as this has been buried by the operation, the overlaying metal must be cleared off on the grindstone, so as to lay bare enough of the end for use.

FIG. 3.



The amorphous "carbonado," or black diamond is very efficient for turning glass, facing stone, and for rock drills; but, for keen cutting tools, I decidedly prefer the larger pieces of bort, or fragments of the crystalline or gem diamond. Properly shaped splinters may sometimes be selected to suit a particular purpose; but, of course, this is all chance. For a correct system of using diamond for cutting, graving, or turning tools, the pieces must be worked to definite and suitable forms.

If a piece of diamond, mounted in the way that I have last described, is held short, and very stiffly, in a wire chuck, running in a small quick-speed lathe, and another mounted fragment is pressed against it, the revolving diamond can be turned to a desired shape by attrition, in which the rubbing diamond suffers an almost equal loss. The dust flies off with a harsh squeaking noise, that may be expressed as "setting one's teeth on edge." With care, the revolving stone may be brought to a needle point, useful for marking, or a tool for a dividing engine; but this form is unsuitable for a cutting or turning tool, by which shavings of metal are required to be taken off; but if a diamond tool of this conical form is held in the vice by its setting, and a piece of steel with a notch in which the point is entered is tapped smartly, it will be broken off in a sloping direction, as shown in Fig. 3, by dotted line *a*. This, used as a graver will take shavings off a surface of hard steel; but for turning tools on hard steel and other metals it is an unsatisfactory practice to depend upon splinters mounted and held radially against the work. Frequent fractures will occur, causing vexation and delay, and a prejudice against this really useful workshop tool. The wire containing the diamond should be held in a simple tool holder of this form. *a* (Fig. 4) is a bar of steel bent at the end to an angle as shown, through this is drilled a hole in which the steel stem *b* of the tool just fits, a saw cut is then made as far as *c*, so as to split the end of the bar, a side screw is tapped into the off half of the split for the purpose of gripping the stem very firmly. The diamond held this way will have almost the strength of a steel turning tool, with the great advantage of retaining an ever-enduring keen cutting edge—at least, as far as I have seen; but should a cutting edge require to be renewed or altered, this may be done by holding the sloping facet at the apex of the cone, against a piece of "carbonado" chucked in the lathe, which serves as a grindstone. This will be apt to make the cutting facet somewhat hollow; which, however, is no disadvantage.

I have worked with diamond tools for years consecutively, and the above method of setting and using them has been from my own practice; but this is, perhaps, but a fragment of what is known concerning them. The limit to the use of diamonds does not so much depend upon their practicable application, as the intolerable dearness of the material. If it were not for this drawback, I have no doubt that, for their hardness and everlasting endurance, large milling machines would be provided with numerous diamond teeth that would shape and dress off all kinds of stone work with great rapidity, instead of their application being limited to the patent rock-boring machines now in use.

## THE INTERNATIONAL INVENTIONS EXHIBITION.—V.

### Railway Plant, &c.

In the preface to Group V., Capt. Douglas Galton says that "the gradual improvements which have taken place in the last twenty-five years in the comfort of railway carriages are traceable to the competition for through traffic of the main lines of railway. Those lines where competition is absent are often treated to scant accommodation, and to antiquated carriages." Unquestionably this statement is true in the main; but we think we could point to some notorious instances in which competition seems to have settled down into a struggle to discover what sort of dirty, badly-lighted carriage the travelling public will put up with. One would have expected that some of the more enterprising railway companies would have exhibited models, at least, of their rolling stock at this exhibition; but with the exception of the South-Eastern Railway Company none of them are represented, for the compound locomotive, which forms so prominent an object in the Middle Court, is exhibited by Mr. F. W. Webb. The S.E.R., as stated last week, exhibit a goods waggon and a coal truck, constructed for running at high speed. These have axles and wheels similar to those used for coaches, rubber buffer and draw springs, screw coupling, and safety chains. Mr. Webb's engine, which has been described as a monster and a mammoth, is really carried on driving wheels only 6ft. 3in. in diameter, while the length over buffer frames is a little more than 27ft. It looks large because the visitor views it from a novel position, so far as locomotives and spectators are concerned, but to the expert it conveys the idea of compactness and power. The high-pressure cylinders, 14in. in diameter by 24in. stroke, are placed outside the frames, and drive the trailing wheels. The exhaust steam from these cylinders is led by pipes inside the smoke box to the valve-chest of the low-pressure cylinder, 30in. in diameter by 24in. stroke, which is placed between the frames beneath the smoke box, and drives an axle in which a crank has been formed in a hydraulic forging press (one of these axles is shown in the rough). The exhaust steam from the high-pressure cylinders is purposely given a long distance to travel before reaching the low-pressure valve-chest in order that it may be slightly superheated. A relief valve, set at 80lb., is placed on one of the pipes leading to the low-pressure chest, so as to limit the pressure which can accumulate there. It may be doubted whether the economy obtained by the expansion of the steam in two cylinders will cover the extra cost of this design; but there are other points which deserve attention, notably the large wearing surfaces provided at important places, which will materially reduce wear and tear, and render the compounds more economical than express engines of the ordinary type. The use of high and low-pressure cylinders also gives four driving wheels without employing coupling-rods. Up to March 31st last one of the earlier compounds, No. 301 Economist, had averaged 301 miles per day for 312 days; and the Dreadnought, which represents the engine exhibited, had averaged for 59 days 291 miles. In fact, all the compounds have been engaged in doing heavy regular work, and they have done it so well that their introduction will leave a mark on locomotive history. The engine exhibited stands on Webb's steel permanent way, with sleepers of trough section, chairs stamped to shape in dies, and lining plates between the chairs and sleepers. Brown paper soaked in tar is used for liners, and all parts are firmly riveted together with one of Tweddell's portable hydraulic machines. Oak keys are used, and never work loose, because the wood swells and fills a recess in the chair, and also because the latter is elastic. There are several other forms of permanent way shown in either this Group or Group III.; but Mr. Webb's exhibit derives its importance from the fact that considerable lengths of it are in use on the London and North-Western Railway. The Acaster Patent Rail Joint Co., of Sheffield, show, in Group III., their two-wedge and three-wedge plans for dispensing with fish-plates. These wedges are rolled with grooves to prevent them shifting, and in the best, the three-wedge, the tightening piece is driven between two other pieces, which bear respectively against the head and the flange of the rail. Mr. Kirkaldy's test gives the strength of a two-wedge joint as 60 per cent. of the strength of the rail; but a three-wedge is said to have 82 per cent., and to weigh only 28lb. There are a variety of improved chairs and fastenings, and several lock-nut arrangements which deserve notice. The exhibits of brakes will probably prove of most interest to the public, so far as Group V. is concerned, and specially noticeable amongst them is the Westinghouse, which is here fitted up with the complete apparatus for working a train of 15 coaches. The 15 brake cylinders are placed vertically at the back, and each is connected with its triple valve and auxiliary reservoir, the whole set being so arranged as to show the working of the brake through a train of the length mentioned, or through a pipe-length of 400ft. The air-compressing pump and main reservoir, which is generally carried under the footplate, are placed at one end of the line of apparatus, and a driver's brake-valve is erected in a convenient position, the whole representing as accurately as possible the actual arrangements and conditions of the brake as applied to a train. The compressed air is forced into the main reservoir by the pump, and, flowing through the driver's brake-valve and main pipe, charges the auxiliary reservoirs throughout the train until the pressure is uniform throughout. So long as the driver's brake-valve and the valves to be used on emergency by the guards and passengers are in the off position the brake cylinders are empty, and the tips of the rods which connect the pistons with the block gear are seen above the cylinders and beneath them, as they are here placed in a line in the vertical position. The triple valve, which is an important feature in the apparatus, is in reality a little piston which carries a slide-valve, and moves up or down when the pressure is increased or decreased in the brake-pipe. When the air-pump is set to work the piston of the triple valve moves up and allows the air to pass into the reservoirs beneath the coaches, while, at the same time, any air which may be in the brake cylinders can escape past the slide-valve into the atmosphere. The pumping being continued the air pressure becomes equal on both sides of the little piston, and it remains in equilibrium. If, now, one of the valves in the train is opened, or a pipe or other connection breaks, the air pressure is immediately reduced on one side of the piston, and it moves the slide-valve into such a position that the compressed air in the reservoir passes into the brake cylinder between the two pistons, and driving them towards the ends of the cylinder forces out the brake rods connecting with the block gear, and the brakes are thus instantaneously applied to all the wheels in the train. The great merit of this brake is that the driver's confidence in it is perfect, for he knows that if it were not in working order it would automatically acquaint him with the fact, while if any serious derangement occurs in the apparatus under a coach, it can be cut out of the system by turning a small tap between the triple valve and the brake pipe. The instantaneous and simultaneous action of all the brakes is readily observed in this exhibit, for as soon as the "driver's brake-valve" is opened the rods of all the cylinders will be seen to rise at once, and as soon as it is closed they all sink back, showing that the brakes have been taken off. The compressed air can also be utilised for communicating between the guard and the driver, for blowing a whistle on the engine, and stopping the train if the warning is disregarded, while a little signal indicates the compartment from which the warning has proceeded. It is difficult indeed to conceive of any arrangements which should be more complete or efficient, and, according to Mr. Harrison, the engineer-in-chief of the North-Eastern Railway, there is great economy in the maintenance of the Westinghouse brake. The standard arrangement adopted by the Vacuum Brake Company is shown at an adjoining stand. A vacuum chamber containing a piston to operate the brake gear is kept in the exhausted state by means of an ejector on the engine, which withdraws the air from the main pipe and, by means of flexible connections and ball valves, from the vacuum chambers and both sides of the brake pistons. As soon as air is admitted to the train pipe the ball valves close the entrance to the vacuum chamber and air is admitted to the under side of the piston, which is forced up by the atmospheric pressure and the brakes are thus applied. The couplings are arranged to separate easily in the event of any portion of the train breaking away. This is the best of the brakes working on the vacuum principle, and is automatic in action. The Welch-Parker-Smith brake is shown by means of a working model, in which a carriage is stopped while at full speed down a gradient of 1 in 12. In this case the brakes act by gravity and are normally on, a heavy piston in a cylinder operating levers which apply blocks to both sides of the wheels. Compressed air or a vacuum is employed to keep the piston up and the brakes off, and while the parts are in order the arrangement is in running condition so long as the pistons are kept up; but should a coupling fail or the vacuum be destroyed or the compressed air leak away (as the case may be), either by design or accident, the brakes are at once applied. By means of a special valve the driver is enabled to reduce the amount of vacuum or air pressure, and so, to a certain extent, can regulate the pressure of the blocks upon the wheels. The Heberlein automatic friction brake is shown in full size, and there are a few others in model or diagrams, which, however, are of little interest in the face of those mentioned above. Signalling arrangements are well shown by W. R. Sykes—the well-known electric interlocking and block system, by McKenzie and Holland, and by Saxby and Farmer, as mentioned in the article on p. 203. The latter firm show a full-size seven-lever cabin with signal-posts and points, and their duplex detector. When the locking handles are once put into position for a train to pass, the points and signals are interlocked, and the position cannot be altered until the train has passed, and by its weight caused a small treadle to make the electric circuit through the block instrument and so unlock the handle. The duplex detector is to avoid danger from a broken connection between the points and their levers, which would allow the signals and the point levers to be shifted without altering the points themselves in accordance with the signals. The detector is a double-action plunger working through slots in the tie-bar connecting the tongues of the points. If the latter have not been put into the desired position, it is impossible to set the signals, for the plungers cannot enter the slots. Contrivances for signalling to and from trains in motion are shown by the Electrical Signal Co., and by Mr. T. T. Powell, of Harrogate. The latter exhibits the model shown at the Crystal Palace, which involves the use of a centre rail, and the system of the former necessitates the erection of contact posts at intervals, which complete the circuit by means of a rubbing lever carried by the engine. The progress of a train can by this means be registered on a drum in the signalman's cabin, and the signals can be repeated on the engine. In connection with signalling arrangements, compensators and arrangements for placing detonators on the line during foggy weather will attract attention. Henson and Co., of Derby, exhibit their patent apparatus for placing the detonators on the line, and indicating by an electric bell whether the fog-signal is on the rail or has been exploded. This is accomplished by means of the detonator itself, which is of the usual shape without clips, and is carried by a holder. As it is pushed out from the box it is made to rub against a contact piece, and so complete an electric circuit and ring a bell in the signalman's cabin. If the detonator should not be required it can be withdrawn, and will again ring the bell as it is drawn back; but should it have been exploded, or merely flattened, it will no longer be thick enough to touch the contact-piece, and the absence of the bell signal will announce the fact that another detonator is required. The case carries 36 of these in a cylinder, and the lever is made to take up the top one. These fog-signalling machines have been at work on the Midland and the Great Eastern Railway for some time, with satisfactory results. The compensator exhibited by Henson and Co. is also a simple and ingenious device. It consists of a weighted pulley, free to move up or down in vertical guides; the signal wire passes round this pulley and is consequently always kept taut. The inner faces of the vertical guides have racks, into which a vee flange on the face of the guide pulley enters as it revolves when the signal wire is drawn upon. The weight of the pulley is thus taken off as it were as soon as there is a pull on the wire, while it at all times keeps the wire taut. A vertical distance of 14in. is provided for the pulley to rise and fall, which is more than sufficient for the longest lengths of signal wires. The Johnson Compensator Company, John Dalton-street, Manchester, exhibit their liquid compensator, which consists of three tubes, the centre one about a third the length of the other two, and fitted with a plunger. These tubes communicate and form the reservoir for the glycerine or other liquid which does not readily freeze. It will be understood that one end of the signal wire being attached to the crosshead of the plunger, and the other to the frame formed by the tubes, an expansion in the wire is compensated for by expansion of the glycerine, and *vice versâ*. The automatic and safety couplings are, perhaps, the most interesting exhibits in this group, but we shall probably illustrate the more promising amongst them in a separate article. The Janney coupler and buffer, which is used to a considerable extent in America, is exhibited by Mr. A. Davis, of Parliament-mansions, S.W., but it is scarcely suited to waggons which have not a uniform height of buffer beam. Mr. G. Turton, of Westminster-chambers, S.W., shows his improved Norwegian hook-coupling buffer, with the patent slack-gathering arrangement for preventing the hook jumping out (an eccentric in the hook), and the springs for keeping the buffer heads in contact while going round a curve. He also exhibits a collection of his well-known patent buffers, in which the piston moves in a long bearing and undue compression of the spring is impossible, while such accidents as happen to the old form with the large hollow plunger are unknown. Mr. Brockelbank shows, in a large working model, his automatic coupling, consisting of a hook on each vehicle, so shaped that on coming into contact one rises over and engages with the other, even if there is a difference of 8in. in the height of the two parts. It is uncoupled by lever and rod worked from the side. One of the best of the automatic couplings is that shown by Mr. G. F. Belling, of Manor Park, Essex. In place of the draw hook there is a ⊐-shaped piece of iron, the upper limb of which supports a pin which swings backwards, and which can be withdrawn from the slot by means of a side lever and rod. A double shackle is pivoted to the draw-bar head, and when two waggons are brought together one shackle rides over the other and enters the ⊐-piece, driving the swinging-pin before it, until it enters so far that the pin falls down, and the coupling is complete. The amount of slack left in this coupling is considerable, and distinguishes it from the devices of those inventors who have forgotten that locomotives cannot always start long trains of loaded waggons unless they are coupled loosely. Amongst safety couplings, that exhibited by Richardson and Greenwood, Harrogate, is deserving of notice. It is worked from the side by lever and rod, and for passenger vehicles there is an arrangement for taking up slack by turning a hand-wheel at the side. Mr. A. Mildred, of Middlesbrough, shows a simple and effective method of fitting ordinary chains so that waggons can be coupled without going between them. It is of the type worked by connecting a link with a rod so as to lift the chain on to the draw-hook by moving a lever at the side. There are a variety of other devices for coupling-up waggons in "safety," down to the simple hook at the end of a pole; but it is to be hoped that some automatic device will be adopted ultimately, as there is considerable risk even when the coupling can be accomplished without going between the buffers. At Stand 663 is shown a device which, if generally adopted, would be a boon to both passengers and station officials. It is a station indicator, the invention of Mr. D. K. Simpson, Liverpool, which has been at work at the Central Station in that city in connection with the Liverpool, Huskisson, Gateacre, and Southport lines. The indicator consists of a sort of Venetian blind arrangement mounted in a frame, the names of the stations being painted on the laths; but the ingenuity of the device is seen when it is discovered that once set it never makes a mistake as to which station any given train will call at. The top of the frame is occupied by wheels carrying figures to indicate the time at which the next train will start. These wheels are operated by little levers at the back, and the time having been set the station attendant consults his "guide," and finds there clearly set forth the exact positions which other levers should occupy. If the train stops at all stations one lever of course turns all the laths outwards and exposes their names; but in the case of the frame exhibited the train service is varied considerably, and there are several levers operating respectively, say three, six, ten, &c., laths, according to the number of stations to be stopped at. The instructions are, however, so simple (they are comprised in thirteen words) that the average station porter learns to work the indicator in about ten minutes, and at a meeting of superintendents held not long ago at the Clearing House, it was much approved, as its general use would save endless questions and prevent not a few mistakes. It should be mentioned that the mechanism can be easily re-arranged to suit the alterations made in the stopping places of different trains. Other inventions which will attract the attention of railway passengers and station attendants and guards are the ingenious improvements in carriage-door locks. Jones and Cunningham at Stand 650 exhibit their patent safety door lock, in which a lever holds the latch until the door shuts, and a spring sends the latch and handle round into the shut position. Mr. W. Payton at Stand 653 shows a different arrangement, in which, as the door closes, a lever catches on a stud and releases the latch. At Stand 628 Douglass and Co., of Queenhithe, exhibit their patent springless lock, which has a latch and a bolt working at different angles. The slightest motion of the latch, such as would be imparted to it in closing the door, throws out a bolt, which holds the door fast. Inventions such as these will relieve porters and others of much unnecessary risk, avoid the objectionable slamming of doors, and probably save some fingers from being smashed. Mr. R. Wright, of Richmond, Yorks, exhibits a model door to prevent the pinching of fingers, the edge being a swinging flap, which readily yields. As he makes a present of it to the public, it is scarcely likely to be adopted. Tramway locomotives are shown by Messrs. Merryweather, the Falcon Engine and Car Co., and Black, Hawthorn, and Co. The last named exhibit Wilkinson's patent, which has cylinders 7¼in. by 11in., four coupled wheels 27½in. in diameter, and a wheel base of 5ft. 8in. In running trim it weighs 9½ tons, and for some time has taken heavy cars of 50 passengers up gradients of 1 in 11½ at Huddersfield. The exhaust and the escape steam from safety-valves is led into a receiver, where it passes into a "hot pot," which also acts as a baffle, and thence, invisibly and noiselessly, into the atmosphere. The Falcon Engine Company's exhibit is a narrow-gauge tramway motor, of the locomotive type, with copper firebox and brass tubes. The cylinders are 8in. by 14in., with 30in. wheels. The wheel base is 4ft. 6in., and the weight, in working order, 9 tons. The steam is condensed in an air condenser on the roof, consisting of 250 very thin copper tubes, fixed in thin cast-brass chambers, and any uncondensed steam passes thence to the smoke-box to be dissipated. An invention of some importance where lines of different gauges are laid down, or found necessary, is the patent wheel and axle of Mr. Mackinlay, of Buenos Ayres, exhibited by Mr. R. McLaren. Without engravings it is not easy to describe this invention; but, in its simplest form, the wheels move along the axle on a screw-thread, and are thus adapted to almost any gauge. Some of the exhibits in this group are obviously only the crude ideas of inventors not sufficiently acquainted with the various conditions of railway work; but, taken altogether, it will well repay the careful inspection of all interested in railway appliances.

## ENGINE-MAKING AT HOME.—VI.

### Fitting the Bed.

WE have presumably all our castings to hand ready for fitting up, and naturally consider where we shall begin. In workshops, of course, all the parts are turned, planed, filed, and drilled before they are brought together at all, and the man who erects simply has to put everything into its proper place ready for working: and a little easing of parts is usually all that is necessary. But an amateur likes to build up as he goes along, the saving of time is thought less of, and gives place before the interest which he experiences in seeing the work grow under his hands. Hence I shall describe the fitting and putting together in detail just as I imagine nine out of ten of my readers would do, and this plan also will prevent too frequently recurring references to the same parts.

Commencing with the bed as the basis of operations, it will be convenient to bolt it first to a heavy block of wood, or stone, or metal, and allow it to remain there while the fitting up of the various parts is being carried forward. Before proceeding, however, with the business of fitting up, it will be well to know what kind of permanent foundation it is to be fixed to, and, if possible, to use that as the basis of operations. Not that it is necessary by any means to fit the engine up in its permanent position, since, if its bed is once got level, it may always be levelled again on any fixing by packing and wedging up. But it will, nevertheless, be convenient at this stage to decide the question of the final fixing, even though we do not make it just at present.

The simplest and easiest bed to make would consist of a block of wood, such as deal, or a harder wood. Its depth will be governed by circumstances. If it is to go directly on the floor of a workshop, it should not be less than a foot deep—better if it exceeds that dimension, and its width should be sufficient to insure steadiness, say 15in., which will, however, necessitate the cutting out of a piece to clear the flywheel (Fig. 79). It may be fastened to the floor with angle brackets, or, if convenient, with bolts, passing through to the beams. Coach screws will fasten the engine bed to its foundation.

A stone foundation should have similar proportions; but the hold-down bolts for the bed must be "leaded" into the stone (Fig. 80). The tapered tail of the bolt, usually rectangular in section, is jagged, and molten lead poured into the easy-fitting hole which receives the bolt holds it firmly in position.

But the best bed-plate is one of cast-iron, shown in Fig. 81. It is stiff, elegant in appearance, and easily fixed both to the floor and to the engine bed. The base is spread to afford the necessary firmness of bearing. It would weigh

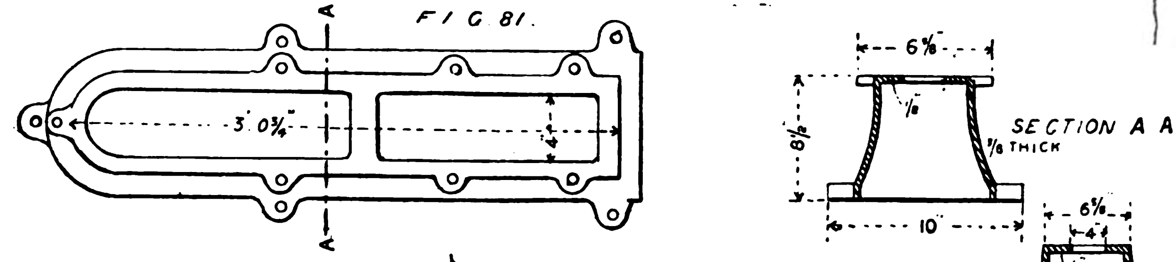

FIG. 81.

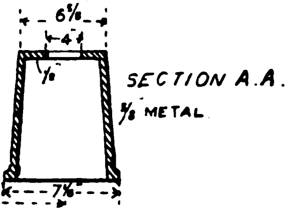

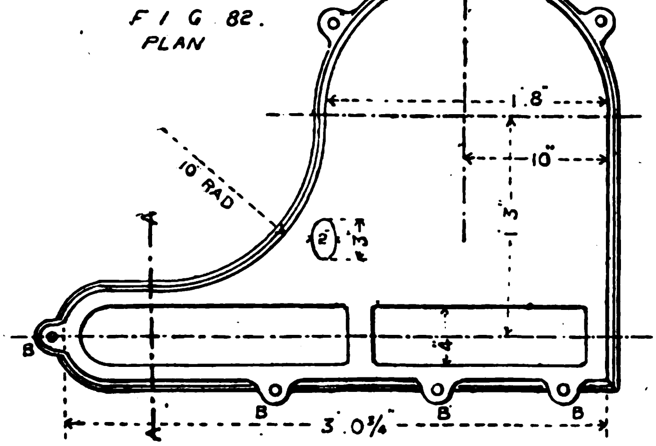

FIG. 82.

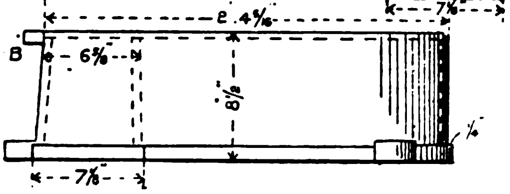

FIG. 82.

85lb. But whoever makes an engine will want a boiler to feed it, and the most compact form of bed-plate, therefore, is that which combines provision for both boiler and engine. Such a one is shown in Fig. 82: it is proportioned for a vertical boiler of from 16in. to 18in. in diameter, that being about the size which such an engine as this would require. Everything is thus compact; the steam pipes are connected up in the shortest possible compass, and the weight of the boiler deadens any vibration which might otherwise be communicated to the foundation by the motion of the flywheel. Further, by plating over the bottom of the casting, and casting an oval hole in the top plate, the foundation will make a very good feed-water tank, and, by passing the exhaust steam through it before allowing it to escape into the atmosphere, the feed-water will be warmed. If it is plated on the bottom, a narrow fillet strip should be cast around its edge to provide for level bearing.

It will be observed that I have given abundant slope to the sides; hence no taper will be planed in the stuff for the pattern, for the pattern moulding face downwards, the top sand will lift away from the internal portions, and the outside of the pattern will afterwards lift away from the bottom sand. The only portions which have to be left loose are the lugs, B, B, B, B, B. If, however, the bottom is plated, the pieces composing the plate must be left loose, in which case the holes in the top of the bed-plate will sustain the central greensand core, aided by chaplets under the boiler plate. This is the bed which I should employ in preference to any other. It would weigh, with the bottom plate, about 240lb.; without the plate, 170lb. Since some of my readers will know nothing about boiler proportions and construction, I will, at the close of these articles, draw and dimension a vertical boiler for this foundation, and show how the pipe connections are made.

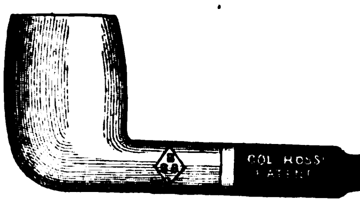
Going back now to the point from which we diverged—the setting of the engine bed—it is not necessary that the bottom of the bed be planed, so long as it is not strained or pulled out of truth in the bolting down. Undoubtedly, planing makes a better job, especially where it fits upon an iron foundation; but it is not essential. If the bottom of the casting is uneven, as it is almost sure to be, it will be packed with paper, thin millboard, or thin slips of metal, in order that it shall not rock upon its foundations, and shall bed evenly everywhere before the bolts are put in. It will be well also to interpose a thin layer of white and red lead between the bed and its foundation before bolting down. If the lugs are not properly packed in the way just described, the chances are that the screwing down of the nuts will break them off. Half-inch bolts will be suitable for bolting down.

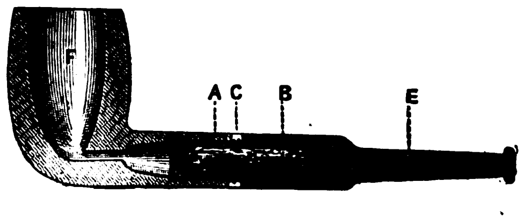
Set now the block upon which the bed has been fastened in a position from which it will not be moved while fitting, wedging up the foundation, or otherwise adjusting it, until the top of the engine bed is as true as the rough casting will allow of, testing the whole with a spirit level. If it has been possible to plane the facings on the bed before putting it upon its foundation, the amount of wedging must be that which will give perfectly accurate results when the top is tried with a level. But I prefer to suppose that the use of a planing machine is not to be obtained, and that the file is to be relied on throughout—no great trouble, since all the surfaces are small.

When the casting is levelled, the facings for the cylinder, the bosses for the guide bars, and the facings for the crank shaft bearings are to be filed, each to their respective heights (Fig. 83), the level and straightedge being employed to test their accuracy. The level must be tried across and along the facings for the cylinder first, then across the guide-bar bosses, until all four are level relatively to one another, and 1$\frac{5}{16}$in. above the cylinder facings, then across the blocks for the crank shaft bearings, until they stand ⅞in. below the guide bar bosses. The heights of these facings must be measured relatively to one another, and not from the bottom of the rough bed. When the facings are very nearly true, the file must be used carefully, and frequent use be made of the straightedge and level, since reducing one portion overmuch will entail a corresponding reduction of all the other faces. Too much pains cannot be taken in this part of the work, for the truth of the after results and facility in putting together will depend to a great extent on the exactitude of the base upon which we build. The guide edges for the joggle on the cylinder foot will be filed to a width of ⅞in. between, and parallel with the edges of the bed.

## COL. ROSS'S IMPROVED FILTER PIPE.

On p. 471, No. 984, we illustrated and described the new pipe introduced by our old contributor, Col. Ross. The *rationale* of the pipe was there fully detailed, and we need only





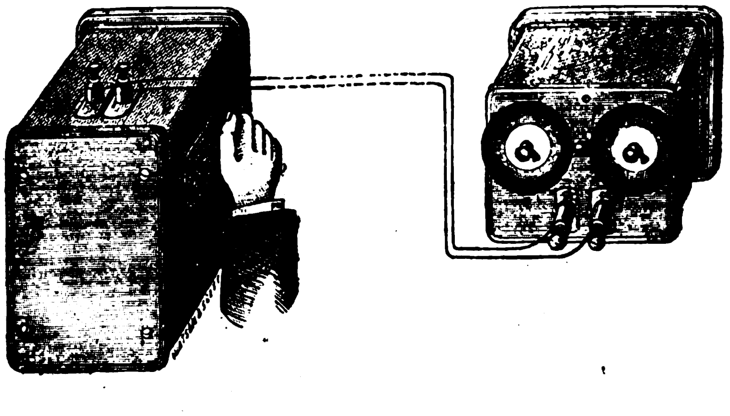
here say that in the new form now illustrated, while retaining all the essential points of his invention, Col. Ross has simplified the pipe and greatly improved the shape, getting rid altogether of the oval receptacle for the sponge.

In the sketch, A is the smoke chamber, B the sponge, C the ivory non-conductor, E the mouthpiece, and F the bowl. Col. Ross claims that the only way to effect a complete separation of the volatile nicotine from the smoke is by *condensing* the latter upon a cold filter, such as a piece of sponge, and that the only way to keep such a sponge sufficiently cold in a short pipe is by isolating it from the source of heat (the bowl) by means of a *non-conductor*, such as we see in the handles of tea and coffee pots. Anyone who understands the subject scientifically will at once see that the essential oils (for this pipe separates two, one thin and dark yellow, the other thick, pasty, and of a brown colour), being quite as volatile as the smoke itself, render all the receptacles, inner tubes, &c., which we see in some pipes, *simply useless*, except for catching the superfluous essential oil which, because it cannot all volatilise as smoke through the narrow bore, condenses in the bottom of every pipe. This is quite another matter from "screening" or "filtering" the smoke, which no pipe, unless made upon the condensing principle, will effect. In the new form of "condensing smoke-filter pipe," the sponge should be carefully cut with scissors out of a small fine Turkey sponge (which are to be had for 4d. each, and make from four to six filters) from the middle of the root to the surface; it should be about 2in. long, slightly wedge-shape, and nicely rounded so as to fit the tube of the pipe, the narrow end being inserted nearest the mouth. Such a filter lasts two or three months.

The Prince of Wales has recently accepted one of Col. Ross's pipes, and a good show of them are on view at the Inventions Exhibition.

## DOMESTIC MAGNETO BELL.

THE annexed engraving illustrates an arrangement of electric bell which dispenses with the battery, and obviates all difficulties with "chemicals" and dirty contacts. The "set" shown in the engraving has been introduced by Messrs. Blakey, Emmott, and Co., of Halifax, to supply for domestic purposes an electric-bell arrangement similar to that used by many of the telephone exchanges. The "set" consists of a magneto-generator, bell, and 24 yards of wire; but obviously the bell may be placed at any desired distance from the generator, in which the current is generated by turning the handle. These instruments are very durable, and will ring over a distance of several miles, while, if necessary, a switch can be placed on the generator with a number of extra terminals, so as to use the one instrument for several bells.



## THE MOTION OF THE STARS.

ON May 23, in the Museum Buildings, Trinity College, Dublin, Dr. Ball, Astronomer Royal, delivered a lecture on "The Discovery of the Motion of Stars in the Line of Sight by the Spectroscope."

Dr. Ball said: I have this afternoon to unfold one of the most modern chapters of astronomical research which has led, and promises still further to lead, to discoveries which are of a nature not to be made by any other means. This method of research tells us what no other method can tell. Let us first see clearly what the problem is. Look at a star with a telescope. Apply the resources of the observatory to the determination of the place of that star. We observe it with the meridian circle. We determine its right arc and declination, and we determine the place which the star occupies in the heavens. Years roll on, and the place of the same star is again determined. The observations are purged from all sources of error, and yet the two places of the star do not agree. There is only one conclusion to be drawn—the star is not at rest. It must have what is called a proper motion. This proper motion varies greatly in different stars. In some cases the star hardly appears to move in the course of centuries: in other cases the motion is sufficiently rapid to be detected in a year or even less. Yet the distances of the stars are so great that the apparent displacement of their positions is but small to ordinary observers. Even the most rapidly-moving star, which hurries along with the stupendous speed of about 200 miles a second, is so far off that it only accomplishes about seven seconds of arc in a period of a twelvemonth. Nine years would be necessary before this star traversed an arc equal to a single minute, while about 250 years must elapse before this star would traverse a distance equal to that subtended by the apparent diameter of the moon. We can show, in a more striking manner, the effects of proper motion by making an attempt to estimate what proper motion can do towards deranging the shapes of the constellations.

Look, for instance, at the constellation of the Great Bear, which has been known from all antiquity. The stars of this constellation are endowed with proper motion, so that the Bear of our Northern skies must have somewhat changed his lineaments from the Bear which Homer said feared to dip in ocean. Dr. Ball then exhibited views of the Great Bear, or rather of the seven principal stars in the constellation. Each of these stars, he said, was endowed with a proper motion, in virtue of which it gradually drifted through space. It was a somewhat remarkable feature that there appeared to be a regular set of the stars in the constellation in one direction. This was at all events true so far as the central stars of the group were concerned. The two first stars of the tail and the three adjacen stars of the body are all apparently drifting in one way, while the two extreme stars at the end of the tail and at the other end of the body are moving in a nearly opposite direction. In consequence of these changes there was a continual development going forward in the features of the Great Bear. They had there two views, one representing the present lineaments so well known to everyone, the other depicting the appearance which the Great Bear was destined to assume. But the rate of change in the great constellation was indeed a very slow one when compared with their ordinary conceptions. The transformation from one picture to the other demanded a period of about 36,000 years. Until within the last quarter of a century astronomers were necessarily in profound ignorance of the movements which stars might have in the line of sight. A star might be hurrying directly towards one system with a velocity of hundreds of miles a second, or it might be receding to the depths of space with a velocity greater than that of a comet in its whirl around the sun, and yet they should have remained in ignorance of that motion, for how could it be detected? No doubt there would be some infinitesimal increase in the star's brightness as its distance decreased, but this would be far too small for the most delicate photometers to grasp, and, even if the change in brilliancy could be discerned, yet it would have been impossible to determine it from the other and well-known causes of variability in stars. A combination of statistics and the theory of probabilities here stepped in, and gave them very precarious assistance. From it they learned that the true proper motions of the stars must on the average be about one-third greater than the apparent motions, but they had no means of conjecturing the true proper motion of any individual star which might in any degree exceed the apparent proper motion. Such was the state of astronomical knowledge when the spectroscope was invented and applied to this particular problem; but how, it might well be said, was the spectroscope capable of affording any information on a matter so recondite—how could the spectrum of a star show whether that star was moving towards the earth, or receding from the earth, or, still more wonderfully, measure the velocity of the motion? All they could learn of the character of the stars should be derived from the rays of light which they transmitted. That ray was usually a very component beam. It consisted of all the colours of the rainbow blended together. The spectroscope acted as the magician's wand, which sorted out all those intermingled colours. It placed the red here and the violet there, and the intermediate lines occupied intermediate positions. It showed how these lines were marked over by dark lines, and it gave wondrous information as to the significance of these dark lines. He had, on that occasion, to dwell on one aspect only of the multitudinous uses to which the spectroscope was subservient to the astronomer. They had not now to dwell on the interpretation of those lines which gave them information as to the actual ingredients of the heated atmosphere which enveloped the star. They had now only to speak of the effect which was produced on the position of those lines by the movements of the star. The lecturer then briefly referred to the wave theory as to light, and dealt with the rotary motion of the sun and of the planet Jupiter. In describing the uses of the spectroscope and the practical application of the instrument in connection with the observations of stars, the rays of light from the star, he said, were received on a large object-glass, and proceeded to a focus. They then passed through a powerful battery of prisms, and were thus expanded out into a spectrum characteristic of the source from which the light had come. In the case of several of the stars there was a considerable range of choice as to the lines by which the measurements could be made. He should, however, refer chiefly to but one star and to one single line in the spectrum of that star. The star of greatest interest in this branch of astronomy was that which claimed special attention as the most brilliant gem in the heavens. It was the peerless Sirius. When this star was viewed in the spectroscope it was found that it belonged to a small and remarkable class which exhibited a spectrum composed of comparatively few lines. These lines were, however, exceptionally dark and broad, and they had been almost all shown to be identical with certain lines in the spectrum of hydrogen. The hydrogen spectrum of Sirius had indeed been confirmed by Dr. Huggins in a very interesting manner. He had obtained photographs of the spectra of Sirius, and on these photographs were depicted many lines on the invisible part of the spectrum, which were, however, sensitive to the indications of the photographic plate. One and all these lines coindided with certain lines obtained in the photograph of the spectrum of hydrogen, as obtained by the electric spark on the earth. Of the visible lines, which they attributed to hydrogen in Sirius, the most conspicuous was that known as the line F on the solar spectrum. In the sun that line was comparatively sharp and well defined. In the spectrum of Sirius F was rather a broad band, not very well defined, except in extremely fine weather. They had there a diagram which gave a view of the F line in Sirius, shown in comparison with the dark line F in the solar spectrum. This figure did not, of course, represent the actual observations, for it was not practicable to introduce the solar spectrum to a comparison with that of Sirius. That view was rather for the purpose of showing the magnitude of the various quantities involved. The broad band was the F line of Sirius, the narrow line was the F line in the sun. The scale showed the motion in miles per second. For instance, the centre of the F line was to the right of the corresponding line in the sun. This would correspond to, perhaps, a tenth part, or less, of the distance of 500 miles, and this would show that Sirius was receding. Continued observations of this star had brought a very unexpected circumstance to light. In 1868 Mr. Huggins first directed attention to this method of research, and he found that the F line of Sirius was displaced towards the red end of the spectrum. This displacement admitted of exact measurement, for it was found possible to introduce into the spectroscope the electric spark in a tube of hydrogen. Dr. Ball then referred to a bright line on the board, and said that if Sirius had no motion relatively to the earth, then, of course, the line F of Sirius should be symmetrically placed with respect to the bright line. As there shown, however, the F line was manifestly towards the red end of the spectrum. It therefore followed that at this time the star Sirius was receding from the sun with a velocity of about 20 miles a second. Subsequent observations confirmed the retreat of Sirius. Even down to 1875, and still later, the same observations were made. About the year 1881 it was perceived that the retreat of Sirius was much less than it had been. From 20 miles a second it had fallen down to two miles a second, and in the subsequent years the retreat of Sirius was entirely reversed. Dr. Ball then referred to figures for the purpose of showing the motions of Sirius from 1875 down to the present year. The difficulties of observation were, he said, such that too great reliance should not be placed on the actual figures of the numerical results. Enough, however, had been done to establish conclusively the remarkable change in the relative motion of Sirius and of our system. It was impossible to pass from the subject of Sirius without offering a conjecture as to why these movements should take place. The movements of this star had already furnished a deeply interesting chapter to the journals of astronomy. Many years ago it had been noticed that the proper motion of this star, as observed in the ordinary manner, exhibited certain fluctuations. It was proved that the motion gave an average of about a thousand miles a minute, sometimes more, and sometimes less. Such irregularities as these admitted of only one interpretation. They should arise from the attraction of some other star in the vicinity. Indeed, in many ways the problem of Sirius was analogous to the ever-memorable researches into the movements of Neptune. The irregularities of Sirius led to the prediction of the existence of a companion to it of considerable size. In some degree even the orbit of this satellite was computed, and the period of the revolution was assigned at about eighty years. These predictions were fulfilled. The companion was detected, and its movements were found to correspond with the time anticipated. It would be of extreme interest to see how far these new movements of Sirius would throw any light on the orbit of the satellite. At present the observations had not reached the necessary completeness. It should, however, be noticed that if the orbit of the satellite were seen edgewise, as was indeed most probable, then during one half of its journey, Sirius would be moving towards us, and during the other half it would be retreating. There was another interesting branch of sidereal astronomy in which these spectroscopic researches were calculated to shed some light, and that was as regarded the motion of the Solar System through space.

## ROSENTHAL'S GALVANOMETER.*

All the galvanometers now in use, such as those of Thomson and Wiedemann, present the same disadvantage—the arrangement of the spirals is very unfavourable, so that in order to increase their sensitiveness, it becomes necessary to considerably increase the number of the wire's revolutions, thus increasing the resistance of the apparatus. It often becomes necessary even to add to a bobbin that is to serve for different experiments a series of bobbins capable of being substituted for one another, according to the requirements of the experiment. Thus Wiedemann's compass always requires three pairs of bobbins, one for thermo-electric currents, one for hydro-electric ones, and one for physiological experiments. By a new arrangement of the spirals M. Rosenthal has succeeded in constructing an apparatus that has a resistance of but 30 ohms, and that far exeeds in sensitiveness all the instruments hitherto known. The apparatus presents the further advantage of being capable of serving for electro-physiological experiments and for thermo-electric currents. The utility of so great sensitiveness is especially apparent in the methods of reduction to zero, such as the measurements of resistances by the aid of Wheatstone's bridge, and the measurements of electro-motive force by Poggendorff's compensation method. The use of this instrument is very simple and its price very moderate. Figs. 1 and 2 show the arrangement of the apparatus. Fig. 1 gives a general view of it. To a marble base, T, provided with three levelling screws, $e$, $f$, $g$, are adapted two columns, $m$ and $n$, which support the discs, $i$ and $k$. To the disc $k$ is fixed the deadener, $d$, held by a screw, $q$, whose extremity enters a groove, $u$ (Fig. 2). At $a$ and $b$ are terminals that communicate with the extremity of the bobbins.

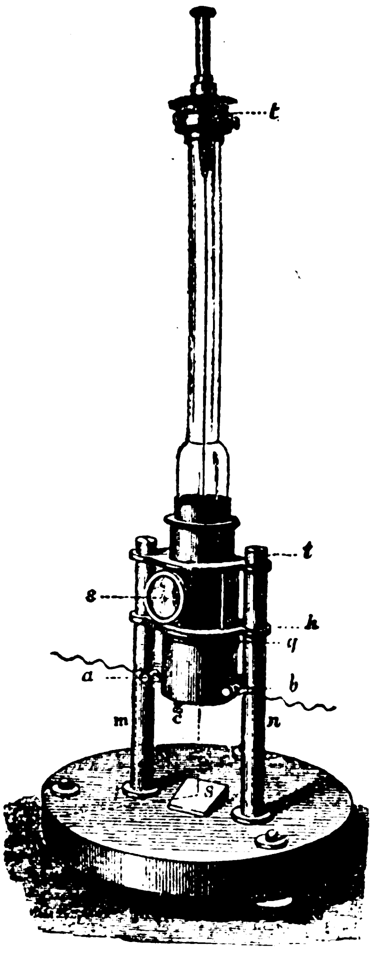


Fig. 1.

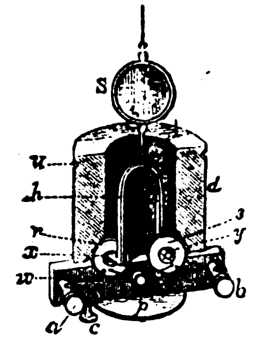

Fig. 2.

Between $i$ and $k$ there is a movable case containing the mirror, and formed of two half-cylinders. To the disc $i$ is screwed a tube, A, which contains the suspension thread, and which is surmounted by a revolving piece to which the thread is attached.

The arrangement of the essential parts of the instrument is shown in Fig. 2. The needle is a small horse-shoe magnet, $h$, to the polar ends of which are fixed two horizontal curved appendages, $x$ and $y$. These latter, which are cut from the same piece as the magnet, form the poles upon which the deflecting action of the bobbin is directly exerted. As the distance between these poles and the bobbins is as small as possible, the action is as efficient as can be. The polar appendages are arcs of a circle whose centre is in the axis of rotation, and they freely traverse the bores of the two bobbins, $r$ and $s$. Each of these latter consists of 200 revolutions of $\frac{1}{200}$in. insulated silver wire wound upon ivory spools that rest in cavities in an ivory support, $w$, to which the terminals, $a$ and $b$, are fixed. This support has the form of a parallelopiped, and engages with two longitudinal slits in the copper deadener. It is held therein by a glass plate, $p$, which, through three small screws, $e$, is fixed to the deadener and closes it at the bottom. The latter (the deadener) is a large hollow copper cylinder. The magnet supports the silver mirror, $s$, at its lower part, and both are suspended by a cocoon fibre. The manner in which the apparatus is mounted may be readily seen. The deadener must be so placed that the slit with which the bobbin-support engages shall make an angle of 45° with the line of the poles. In order to facilitate the manipulation connected with the regulation of the instrument, there is placed upon the marble base a mirror, S, which reflects the whole interior of the apparatus in the direction, T.

The dimensions of the instrument are as follows:—Total height, 18in.; height of tube, 10in.; height of deadener, 1·5in.; external diameter of deadener, 1·5in.; diameter of cavity of deadener, 0·8in.; height of magnet, 1·0in.; weight of magnet and mirror, 60 grains; external diameter of bobbins, 0·46in.; thickness of bobbins, 0·12in.; diameter of bore of bobbins, 0·2in.; resistance of the two bobbins, 39 ohms. In order to give an idea of the sensitiveness of the instrument, M. Rosenthal cites the following data:—(1) Without compensating magnet (of Hauy), a deflection of 0·04in. is equivalent to $54 \cdot 10^{-10}$ amp., the distance from the scale to the mirror being 9ft. (2) With a compensating magnet and the same distance of the scale, a deflection of 0·04in. is equivalent to $12 \cdot 10^{-11}$ amp.

The current from a German silver thermo-electric pile due to a difference of 10° C. temperature at the solderings, and traversing 1,000 ohms, gives a deflection of 4·8in., the scale being 9ft. from the mirror. The inventor has verified the ratio of the slight deflections to the intensities. To this effect, he placed a galvanometer in a derived circuit taken from a platinum wire 3·28ft. in length, stretched in a straight line. The principal circuit was formed of one Leclanché element of 6,600 u. s., and of the platinum wire. In causing the distance between the two points of derivation to vary upon the platinum wire, deflections of the galvanometer proportional to such distances were obtained. The following data are given by M. Rosenthal:—

| Distance of points of derivation on rheostat. | | Deflection of scale. | | Means. |
|---|---|---|---|---|
| 10 | .... | 6·0 | 6·0 | 6·00 |
| 20 | .... | 13·0 | 12·0 | 12·50 |
| 30 | .... | 18·0 | 17·0 | 17·50 |
| 40 | .... | 24·0 | 24·0 | 24·00 |
| 50 | .... | 29·5 | 30·0 | 29·75 |
| 100 | .... | 59·5 | 61·0 | 60·25 |
| 200 | .... | 118·0 | 122·0 | 120·00 |
| 300 | .... | 176·0 | 184·0 | 180·00 |
| 400 | .... | 240·0 | 245·0 | 242·58 |
| 500 | .... | 296·0 | 305·0 | 300·50 |
| 600 | .... | 355·0 | 267·0 | 361·00 |
| 700 | .... | 415·0 | 432·0 | 423·50 |
| 800 | .... | 476·0 | 495·0 | 485·50 |

The concordance is quite sufficient, when we take into account the imperfection of the experiment. The errors do not exceed the limits that ought to be expected with the experimental arrangement that the inventor chose. M. Rosenthal has made a series of measurements of resistances in order to ascertain the degree of approximation that the instrument is capable of reaching, and has found that it is possible to estimate variations of 0·005 per cent. The instrument is peculiarly convenient for electro-physiological experiments, and in these is capable of rendering genuine service.

## INOCULATION FOR CHOLERA.

The statements made in connection with the alleged success of cholera inoculation in Spain are thus commented on by the *Lancet*:—

The *furore* excited by Dr. Ferran's alleged protective inoculation of cholera continues unabated, or rather with increasing ardour. Last week it was reported that he had operated upon 8,000 persons in Valencia alone, including two Madrid doctors—Moreno and Tolosa—who thereby became converts to the new doctrine. It is also stated that four hours after their inoculation they experienced the cramps, diarrhœa, fever, and delirium of cholera, and that after sixteen hours "they were all right again." Further proof of the efficacy of the measure is cited from the Alcira Hospital, where all the inmates were inoculated, with the exception of two, who declined to submit to the operation. Cholera attacked these two recalcitrants, and they succumbed to the disease. It may be remembered that Dr. Ferran adheres to the bacillary doctrine of the etiology of cholera, but that he declares that Koch's comma bacillus is but one stage in the development of an organism whose germs he avers to have discovered. Although we are unwilling to condemn on *a priori* grounds a discovery of such moment as this would be if verified, we are yet very reluctant to admit that such vaccination can protect from true cholera, or to see in the results as reported anything more than coincidences. Asiatic cholera is not prevalent in Alcira, nor, so far as we know, has it reappeared anywhere in Europe this year, and therefore the conditions of a crucial test are wanting. We are not surprised at the excitement that has been caused by the announcement of the alleged prophylactic; for the history of epidemics of this disease shows how much the people dread its invasion; and they would willingly submit to any measure that promised them immunity from the plague. It is significant that at the recent conference at Berlin not even Dr. Koch himself as much as hinted at the possibility of a protective vaccination amongst the measures of meeting the disease; and Ferran's work was only cursorily mentioned by one speaker, Professor Virchow, who believed that the various forms described by Ferran were the results of disintegration of the bacilli, and not stages in their evolution. The matter has, however, reached a stage in which it ought not to be disregarded without a full and sufficient investigation; and although we doubt very much the possibility of arriving at any satisfactory conclusion except in time of epidemic, it is very desirable that Dr. Ferran's labours should be submitted to such an examination by competent and trustworthy authorities. We fully approve of the step somewhat tardily taken by the Spanish Government in prohibiting any further inoculations until such inquiry has proved the efficacy of the measure. For if the whole thing be proved fallacious, the task of dispelling the delusion will be the greater the larger the number of the inoculated; and if it be shown to be really efficacious, no harm will be done by deferring it until this is proved. The position of Dr. Ferran is a difficult one; for, although he has acted in good faith, he must either be a misguided enthusiast who has pushed his conclusions far beyond their legitimate limit, or a great discoverer. Pending such an inquiry it would be unfair to judge him, but we cannot refrain from once more pointing out that to rely upon "protective vaccination" and to suffer the continuance of those insanitary conditions that favour the spread of cholera would inevitably lead to disastrous results. Nor is it possible to view with equanimity the prospect of an application of these inoculation measures to other specific diseases, an extension which would be sure to be attempted if Dr. Ferran were proved to be in the right.

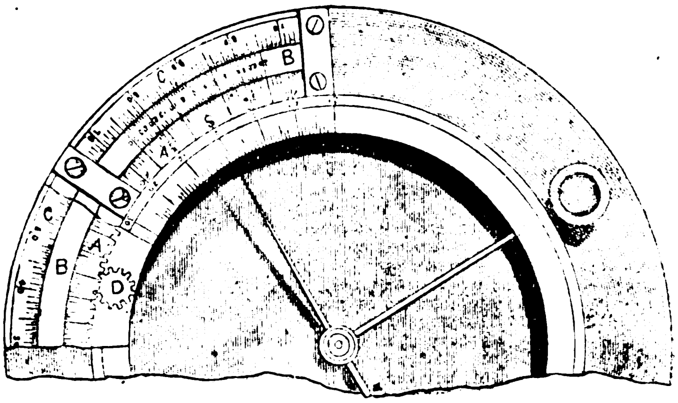
---

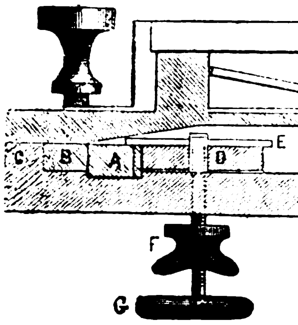
* From *La Lumière Electrique.*

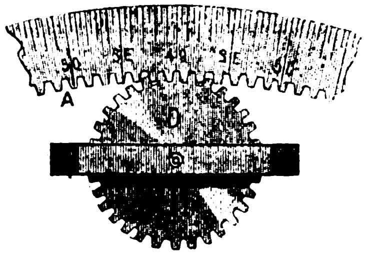
## NIXON'S COURSE READING ATTACHMENTS FOR TRANSITS.

THE device shown in the annexed engraving is probably, says the *Scientific American*, the most important improvement made in surveying instruments since the invention of the transit some fifty years ago. The great source of error, in producing meander or preliminary lines with either a transit or a compass, has always been in the necessity of calculating the course of each line by either adding or subtracting the deflecting angle to or from the preceding course. Especially are these calculations liable to error when the addition or subtraction of the deflection angle will put the course of the new line into another quadrant from the one in which the preceding course was located. Every engineer of any experience knows the great loss of valuable time and the annoyance often caused by errors of transit men in calculating courses.

The inventor of this improvement, Mr. T. L. Nixon, of Tacoma, Washington Territory, has had extensive experience in transit work, and after some study contrived this simple but valuable improvement. Any one can understand the working of the instrument by a glance at the illustrations. The course ring, A, can be revolved upon the lower plate, or can be clamped to it at any desired point. This ring is divided into the different quadrants, and graduated so as to read by the vernier exactly the same as the vernier reads upon the outer circle, which circle is graduated from 0 to 180°, just the same as the old style of instrument. Therefore, instead of deflecting an angle upon the outer graduated circle each time and making the calculation of the course, with this instrument the zero of the vernier is set at the course of the back sight, and then, when the upper plate is unclamped and the telescope directed to the forward tack and the upper plate again clamped, by a look at the vernier and course ring the new course is read at once correctly, down to the finest graduation of the instrument, no matter whether it is known which way the deflection was made or not.







The revolving movements of the ring, A, are accomplished by means of the pinion, D, which is rigidly mounted on a spindle extending through the lower plate, and provided at its lower end with a thumb wheel, C, by which it may be readily turned. The ring, A, may be clamped in any position by turning the jam nut, F, so that it will bear against the plate. The vernier, B, is attached to the upper plate, and is fitted to travel immediately outside of the ring, A, and inside of a graduated circle, C, of the lower plate. The vernier is graduated to read minutes or half minutes, as desired, and the graduation extends to both edges, so that it will read precisely the same angle upon either the course ring or the circle, C.

## PHOTOGRAPHIC MAPS OF THE STARS.*

### By S. J. Perry, S.J., F.R.S.

IT is interesting to watch the steady progress that is being made in a most important branch of celestial photography. The accurate mapping of stars, which is so fundamental in astronomy, is a work always very laborious, and for certain positions in the heavens almost impossible. The lamented death of Chacornac put a stop for a time to the valuable series of ecliptic charts that he had constructed with such marvellous accuracy, and when an attempt was made by the brothers Henry to complete his great work, they found, on arriving at the portion of the sky traversed by the Milky Way, that the task of mapping by hand with the required accuracy all the stars above the 15th magnitude was beyond their powers. Recourse was therefore had to photography, and they have now constructed an object-glass that gives good results down at least to the 14th magnitude stars. The immediate object of Messrs. Henry was to complete the ecliptic charts of Chacornac, but it is to be hoped that their success may encourage them to extend ultimately their field of operations.

In the meantime most excellent results in the same direction are being obtained nearer home by one of our amateur astronomers. Mr. Howard Grubb has lately constructed an 18in. Cassegrain with a very short focus, with the view of enabling Mr. J. Roberts to photograph at his private observatory, Kennessee, Maghull, the whole of the northern heavens. The mirror has been excellently mounted, and is now used on every fine night. The 3in. photographic plates cover an area of the sky two degrees square, or about 16 times the area of the full moon. I had the pleasure of examining one of the plates two days ago, and found, on comparing it with Argelander's star atlas, that the photograph contained, along with the 58 stars of the map, at least 32 new ones, all probably below the magnitude 9.10 at which Argelander stopped. The exposure of the plate was 20 minutes, but Mr. Roberts is of opinion that rather less than a quarter of an hour will furnish the most advantageous results with the plates he is now using. To facilitate work, and to secure always perfect adjustment of instrument, Mr. Grubb is at present constructing for this Cassegrain mirror a collimating eyepiece, designed by Mr. G. Johnstone Stoney, which will enable the observer to collimate his telescope with the greatest nicety, and with very little loss of time, whenever the position of the instrument may require to be altered. The use of this Cassegrain is confined entirely to photography, and it is mounted on the same stand with a refractor, thus forming a duplex equatorial similar to the one that is doing such excellent work in the hands of Dr. Huggins. The progress of Mr. Roberts in the construction of his celestial atlas will be followed with the keenest interest by all lovers of photography, and we must all earnestly hope that health and strength for the prosecution will correspond to the zeal shown in the undertaking of so great a work.

---

## JABLOCHKOFF'S NEW BATTERY.

THE following account of a new battery, called the anti-accumulator, has been presented to the Paris Academy of Science by M. Jablochkoff, and appears in the *Comptes Rendus*, from which we make the following extract:—It is a battery with three electrodes, and comprises first an oxidisable metal which forms the first electrode; then a plate formed of a slightly oxidisable metal, such as lead, or of porous carbon capable of polarisation, forming the second electrode; and, lastly, another electrode formed of lamellæ or tubes of very porous carbon immersed in air. Among the various types employed, I will describe only the most recent. It is composed of a flat vat of lead, or lined with lead, in which are placed fragments of the oxidisable metal, which may be sodium, sodium amalgam, zinc, iron, &c. When this metal is put into position, the vat is filled up to its edge with any spongy matter, packing cloth, wood sawdust, &c. Two cases may then occur: if we use sodium it is not necessary to introduce water, as the sodium becomes oxidised, forming caustic soda, which attracts moisture; if the metal employed is zinc or iron, the spongy mass is moistened with a solution containing either common salt or, preferably, chloride of calcium, which attracts and retains moisture. Lastly, upon the levelled spongy mass is placed a range of tubes of porous carbon. For this grouping I prefer to substitute for the leaden vat one of paraffined carbon. The action set up in this battery is as follows: when the element is formed but remains open there are established local currents between the oxidisable metal and the electrode upon which it is placed. This latter is polarised, and its potential rises until it has reached that of the metal; the action is then arrested or reduced to a minimum. If we wish to collect the exterior useful current, it is sufficient to connect by a conductor the electrode thus polarised to the other electrode of carbon; the discharge begins; the local currents resume their action, and restore to the electrode its charge in proportion as it is expended. The elements of this battery have been determined on several occasions, and found as follows: the electro-motive force depends on the oxidisable metal employed; with sodium amalgam it is 2·2 volts; with zinc, 1·6 volt; with iron, 1·1 volt. The internal resistance of an element measuring a decimètre on its side varies between a quarter ohm and half an ohm, according to the thickness of the spongy layer and its degree of moisture. The external dimensions are one decimètre in square by 25 millimètres in height; the weight is from 200 to 250 grms. The advantages of this battery are its simplicity and convenience of manipulation. It is managed in this manner: the elements are ranged in batteries of a regular form, and connected in groups of ten at most. The battery may be charged with oxidisable metals for several months, and it is merely necessary to renew the liquid from time to time. For that purpose we take a group of elements, steep it in pure water, withdraw it, let it drain, and then steep it in a trough filled with a solution of chloride of calcium. This is taken up by the spongy body, the excess is poured away, and the battery returned to its place. This simple operation needs only be performed very rarely if the battery is used for such work as bells, telegraphing, &c. If the current is employed for light or for mechanical power, the liquid must be renewed every 24 or 48 hours. We may remark that this battery works only when its current is utilised, and that it gives off no odour. It utilises the local currents which are so injurious in ordinary batteries, and, above all, it yields electric energy very cheaply, as the metals are employed in the state of waste, filings, turnings, &c. If we suppose that iron is used, it is known that to obtain one h.-p. for an hour 850 grms. of metal must be consumed. But iron turnings are worth five centimes per kilo, or for this quantity four centimes. As for the chloride of calcium it has no value. We may therefore affirm that this battery gives the energy of 1 h.-p. hourly for an outlay of 5 centimes (say one halfpenny)—which has to be proved.

## THEORY AND PRACTICE OF PHOTO-MICROGRAPHY.—I[*]

By Maurice N. Miller, M.D., Instructor in Biology in the University Medical College, New York.

If an illuminated translucent picture on a plane surface be placed at a considerable distance from a convex lens, a much diminished image will be formed at a point near the focus of the lens. If a minute and brightly illuminated translucent object be placed near the focus of a convex lens, an enlarged image will be found at a considerable distance from the lens. The conditions described in the first proposition, using an ordinary photographic negative, a microscope objective, and a sensitive film to receive the image, are required in the production of micro-photographs. The second arrangement, introducing a mounted microscopic object, a microscopic objective, and a sensitive film, presents the conditions necessary in the production of photo-micrographs. A micro-photograph is simply a reduced copy of a photographic negative; while a photo-micrograph is the fixed image of an object greatly enlarged by the microscope. It is with the production of the latter that we are engaged this evening. In order that we may the better appreciate the conditions required in the production of enlarged pictures of minute objects, let us examine the simplest arrangement that may be employed for such purpose.

First, a microscope stand is required. This is placed on a table so that the optical body is in a horizontal position. The eyepiece is now removed and a long bellows camera box is connected with the microscope tube so as to make a light tight joint. The whole being firmly fixed to the rigid table, the latter is placed so that the sun may shine on the mirror of this microscope, and on this alone. (Let me say just here that it is with translucent objects only that we have to deal. Little effort has thus far been directed toward the production of enlargements of opaque objects, and, inasmuch as we can operate with the lowest powers only in such work, it is not probable that the results thus obtainable will ever be much sought for.)

We now proceed with the description of the steps necessary to produce an enlargement with our simple apparatus. A microscopic object is placed upon the stage and then held in position by the spring clips. A piece of blue glass is now placed beneath the stage and the mirror; so adjusted that the sun's rays are brought to a focus a little beyond the object to be photographed, and, for illustration, we will take a mounted specimen of a small insect, which will afford us sufficient defferentiation with moderate amplification. A 1in. well-corrected objective is put on the microscope, and we adjust the camera so that the ground glass is about 18in. from the stage. Now, covering the head with an opaque cloth in the ordinary way, we reach the coarse adjustment, and obtain an image, which we then sharpen with the fine focussing screw. You will observe that the camera is not too far distant, and we easily reach the milled heads of the focussing mechanism. By the time we have proceeded thus far it is probable that the sun has moved, or, more correctly, the earth has progressed, so that the mirror needs another adjustment in order that the picture may have purely central illumination. Well, we give the mirror a final touch, substitute our sensitive plate for the ground glass, and expose. With the low power we are using there is plenty of room for a little cap over the nose of the objective, and this affords the best simple means of exposure. If higher powers be employed, and consequently less distance between the lens and the object, a swing shutter must be introduced within the camera.

Well, what is our result? We develop, and, if we have been moderate in our desires, using a low power—not endeavouring to amplify beyond thirty diameters—we will get moderately successful pictures. Our principal difficulty is to get an even illumination. The centre of the field will, perhaps, be over-exposed, while a ring of darkness appears without this point. This is due to two principal causes, and one of them is easily eliminated. Reflections come from the inside of the tube, or from the mounting of the objective. Even the edge of the stage diaphragm may be bright enough to cause trouble, and the edge of the mirror-mounting introduces another source of unequal illumination. It is not enough that the afore-mentioned places be black—they must be *dead black*. I will allude to this again. But a much more serious cause of unequal illumination is found in the scattering rays from the mirror itself. The whole method is deficient.

Let me now describe, in contrast with the above, what I regard as the very best arrangement that can be made, with ample means and convenient surroundings. We will then compare the two, and see how far we may be able to dispense with the more expensive and complicated apparatus. The first question to settle is the source from which we must obtain our light; and I unhesitatingly answer directly from that great source of all light—the sun. Electricity comes nearest to sunlight in value for photo-micrographic purposes; but unless the operator has a very large stock of patience I advise him to have nothing to do with it. The only form that is of the slightest use, except for low amplification, is that evolved from the arc lamp, and thus far we have no regulators that are certain to remain in the optical axis of our instruments for a single second. The incandescent lamp is of no use, except as previously for very unambitious attempts with low powers. I have travelled most thoroughly and conscientiously this electric road, and let me sum up my advice to you in this little word—*don't*!

The calcium jet is far better for our purposes than the electric light. It is easily regulated, can be kept steadily in adjustment, but it is a very expensive luxury. Besides this, there is a certain hardness, a cold black and white that is inseparable from this mode of illumination. I used to think I could pick out calcium-light negatives from pictures made with other modes of illumination. I don't know that I would be willing to say as much now, but that there is a cold chalk-and-charcoal feature to prints from such negatives I presume many besides myself have noticed. The minor methods of lighting—by oil, gas, &c.—do not deserve any consideration at our hands at this time. We are engaged in the attempt to produce the very best results obtainable, and I know very well that no amateur is going to be satisfied with silhouettes made with a dark lantern attached to a camera box. I never knew of a lens with power enough for an amateur. Far be it from me to discourage small beginnings; but I want you all to aim high, and never rest until you can say your work is good enough to offer as patterns for others to equal.

In presenting what I regard as the best arrangements for our work, it will, in reality, be a description of the apartments belonging to my new laboratory, now in course of construction. First, a room which has one window, at least, facing the south, is a great desideratum. But, as an illustration of what may be done under disadvantages, many of you may, perhaps, be surprised to learn that the laboratory of the late Col. Woodward was so located that all of his work had to be done before eleven o'clock a.m., on account of the shadow of an adjoining building. Premising that we have a southern exposure, we must next be able to secure absolute darkness in our room. This is best accomplished by inside shutters of painted wood, although all the windows save one may be darkened in any way thought desirable. Let me again say that nothing short of absolute darkness will answer. With our present highly sensitive plates, the twilight of our old-fashioned dark rooms will not answer. Our one room may possibly answer, not only for the purposes of an operating apartment, but also serve for the development and preparation of the plates. Indeed, we may work quite conveniently, using the room in this double capacity, if we have at our command one or two dark boxes in which to allow slow developments to proceed while we are otherwise engaged, and while the room is lighted. Of course, a separate dark room is preferable. Attached to the window-ledge, and outside the window, level with the bottom of the latter, we have a strong, rigid shelf for the heliostat. This shelf should be so strongly affixed that it is in reality a part of the building. Mine is of slate (although painted oak answers very well), and the length is equal to the breadth of the window, while the width should be at least twenty inches. To the window-frame, which is, of course, the one with the southern exposure, we must affix two inside shutters. By this I mean a double shutter, opening vertically in the centre of the window. The left half of this shutter, as you face the window, need not be hinged, but fastened permanently and rigidly to the window-casing. The right-hand shutter is hinged to the casing, and must be well fitted, so that, when closed, the room is instantly in perfect darkness. This requires the service of a good mechanic.

Another shelf is required inside our room for our microscope and accessories, and for this purpose a pine plank, two inches thick and ten by twenty-four inches, answers perfectly. This is fastened to the bottom of the window-casing by one end, and the other end is supported by a brace or leg to the floor. This should be a permanent fixture, or, at least, so fastened by screws as to be perfectly rigid. I should have said in the beginning that the building, if in a large town, ought to be on a good foundation and free from tremor. Our large buildings that tremble with every passing truck will not answer the purpose.

One more fixture, and we are ready for the placing of our apparatus. We require no camera box other than our apartment—we simply need a frame to hold the ground glass and the plate-holder. A frame of this sort can be easily made, or a camera box may be utilized by removing the front. This should be affixed solidly to a stand that may be raised or lowered—an iron camera stand answering the purpose perfectly—especially if, after the proper position has been obtained, it may be readily and securely fixed to the floor.

(*To be continued.*)

# SCIENTIFIC SOCIETIES.

## ROYAL MICROSCOPICAL SOCIETY.

The eighth meeting of the session was held on the 13th ult., at King's College, Strand, W.C., the President (the Rev. Dr. Dallinger, F.R.S.) in the chair.

Mr. Beck exhibited the "Star" microscope (in two forms) which his firm had recently brought out, with a view to supply a want which had been felt for an instrument which should be at the same time very cheap, but yet thoroughly reliable. To explain what he meant by cheapness, he mentioned that it was proposed to offer the cheaper of the two forms for 3 guineas, with two objectives (1in. and ¼in.). He believed it would be found that the instruments were suited to all the ordinary requirements of the botanist, the student, or the amateur. He had thought of reading an introductory notice of the instruments which had been prepared for circulation; but, instead of doing this, he thought it would be better to present an instrument to the society, so that those who were interested in such matters might have the opportunity of seeing what could be done with it.

The President, in thanking Mr. Beck for his donation, said he was exceedingly glad to welcome such an instrument, for he was himself constantly realising the need of a very cheap form of microscope which was capable of doing work in a reasonably good manner. A large number of boys and youths were prevented from taking up microscopical studies by the expense connected with them, and to be able to have a microscope of this class with two objectives at the price mentioned would therefore be a great boon.

Mr. Guimaraens exhibited six slides of Pathogenic bacteria prepared by Dr. A. C. Abbott, of Baltimore, U.S.A., from materials supplied by Dr. G. M. Sternberg, and mounted according to his directions. He considered *Bacillus tuberculosis* in sputum, stained by Frenkel's method, and *Bac. anthracis* in liver of rabbit, deserved especial commendation. There was also an interesting slide of *Micrococcus* of swine plague, pure culture. Dr. Klein maintains the disease is caused by a *Bacillus*, whilst Drs. Salmon and Sternberg consider the form to be a *Micrococcus*.

The President called particular attention to the slides, which he considered were very beautifully mounted, bringing out the *Bacilli* in a most perfect manner.

Mr. Groves exhibited and described one of the new Cambridge rocking section cutters, the principle of which was somewhat new. The razor was firmly fixed at one end of the bed-plate, the imbedded specimen being held in a brass tube fitted upon the end of an iron arm, which was mounted upon trunnions after the manner of a gun. There was an ingenious contrivance by means of which the arm was raised clear of the blade, the section being cut as it descended, and dropping directly upon the slide upon which it might be mounted. The machine was capable of cutting the thinnest possible sections. During a recent visit to Cambridge he had found this machine to be the one in general use. In reply to questions, Mr. Groves stated that the machine was not adapted for freezing, nor for cutting sections of hard substances; but for soft tissues it worked admirably, and, although the sections were not cut in a straight line, they were parallel to each other, and the arc described was so slight that it made no practical difference to the flatness of the section.

Mr. Crisp exhibited a mirror made by the Bausch and Lomb Optical Company, to which was fitted a diaphragm with an oblong slit.

Mr. J. Mayall, jun., said that the principle of having a diaphragm over the mirror was applied by Dellebarre in the last century, and had been subsequently repeated. He remembered having seen Dr. Charles Robin use similar diaphragms, which he found very useful.

Mr. Crisp mentioned that a short time ago a traveller in Asia gave an account of his discovery of the "Wax insects"; but stated he had no means of examining them otherwise than by the naked eye. This led him to look up the account of Gray's water microscopes, in order to call attention to the very simple means by which magnifying power might be obtained under the circumstances in which this traveller found himself placed. Even a drop of water on a piece of glass would have furnished the power required. Mr. Mayall had constructed a model of Gray's apparatus, which he would describe.

Mr. J. Mayall, jun., said that Gray had described his process very clearly. He employed a plate of metal $\frac{1}{16}$in. thick, with a hole drilled through it about $\frac{1}{30}$in. in diameter, one side of which was countersunk to $\frac{1}{8}$in. in diameter, and the other side to about half that extent. A drop of water was then put in each of the countersunk spaces, and it was quite surprising how much magnifying power was obtained, and how clearly the object was shown. Gray suggested that a little cavity should be made in the support in which to put a drop of water containing organisms for examination; but this was not quite so successful. It was not necessary to employ metal for the purpose, as a piece of cardboard or wood answered perfectly. Gray's object was to make a simple as well as an effective apparatus, and in this he had been quite successful, and when an observer found himself without a lens he could not do better than follow the suggestion. Gray found it preferable to use a solution of isinglass, which would remain where it was placed better than water.

Mr. Beck said that some years ago, before the race of street "Patterers" became extinct, there used to be a man who went about selling microscopes made somewhat on this plan, but the lens was made of a drop of Canada balsam.

Mr. Mayall said that in addition to Canada balsam there were other substances, such as castor oil, and, in fact, many of the highly dispersive oils, which would give even better results.

Dr. Maddox read his paper, "An Experiment on Feeding some Insects with a 'Comma' Bacillus, and also with another Bacillus (*Bact. subtilis*)," illustrating the subject by preparations exhibited under the microscope.

Mr. Cheshire said that he must, in the first place, congratulate Dr. Maddox on the time he had been able to keep his bees alive in a state of isolation. They were not at all easy to keep so under ordinary circumstances. He had tried himself some similar experiments, and thought he had succeeded in infecting *Musca Vernitoria*; but it might be well to remark that in one hive bee he had found eight or ten distinct kinds of bacilli, one of which had a distinct curvature. Amongst bee keepers there used to be an idea that the bees had no diseases, although there was one affecting the larvæ, but directly a careful examination of the bees was made it was found that they were subject to a great many. One kind had the curious effect of causing all the hairs to fall out, and on examining bees which were so affected he found them all to contain large numbers of the short red bacillus. If anyone intended to experiment in these matters it might be useful to know that if the bees were fed with food stained with aniline dyes very curious effects were produced upon the internal organs. Differentiation took place within the body, and when they came to dissect them afterwards they would find it a very great help.

Mr. Crisp announced that the Council had decided to place one of Prof. Abbe's apertometers in the library for the use of any of the Fellows who might wish to test the apertures of their objectives. Also that it was intended to publish in the *Journal* in future portraits of the presidents of the society. It was also contemplated to publish the portraits of past presidents, but as it would be quite impossible to give whole-page plates of the whole 18, it was intended to give one of Prof. Owen, as the first president of the Microscopical Society of London, and another of Mr. Glaisher, as the first president of the Royal Microscopical Society after the charter, the others being printed in two groups. To enable the plan to be carried out they would be glad if any Fellow of the Society who had photographs of either Dr. Lindley, Mr. Jackson, Dr. Lankester, Mr. Farrants, or Mr. Reade, would lend them for the purpose of being copied.

Dr. J. D. Cox's paper, "Structure of the Diatom Shell, Silicious films too thin to show a broken edge," was read.

Mr. E. Wethered read his paper on "The Structure and Origin of Carboniferous Coal Seams," the subject being illustrated by large diagrams, as well as by numerous preparations exhibited under microscopes.

The President said he should only be expressing what he was sure would be the feeling of the whole of the Fellows present in thanking Mr. Wethered for his very interesting paper.

Dr. Hudson's paper on "Four new species of the genus Floscularia and five other new species of Rotifers" was read. The paper described F. mira, F. mutabilis, F. calva, F. edentata; Corrochilus dossuarius, Notommata spicata, Stephanops armatus, Pompholyx sulcata, and Taphrocampa ocellata.

Mr. Mayall, jun., said he wished to correct and supplement certain points in his description of Nobert's ruling machine as reported in the *Proceedings* of the April meeting. (1.) The divisions to five minutes in arc on the bands of silver imbedded near the circumference of the division plate were in all probability made by means of a large circle divider, and from them the 21 (not 20) rows of "dots" would have been made with great accuracy. The divisions, therefore, should not have been referred to as supplementing the "dots," but as the prime factor of accuracy of the dividing engine. (2.) The stud and dots might have been used for cutting toothed wheels, but not for ruling diffraction gratings or interference plates. These latter would require the greatest possible accuracy, and therefore Herr Nobert would assuredly adopt the most certain method, which was to work with the division plate and the micrometer microscopes. The tangent screw caused the division plate to rotate with great accuracy, so that Herr Nobert may not have found it necessary to inspect the divisions by the micrometer microscopes for each line. He may have tabulated the error of the tangent screw and made periodic allowance for it. (3). In order to reduce the motion in arc when ruling fishplates, where the movement of the fishplate represented the size of the arc motion of the division plate, Herr Nobert would probably use the arc motion only for the production of the bands of lines, and in moving the fishplate over the blank spaces between the band would utilise the fine micrometer screw attached to the agate plate, fitted within the hollow steel cylinder carrying the test-plate, by which the bottom could be easily moved $\frac{1}{2000}$in. (the average width of the blank spaces between the bands), or even less. In this way he would reduce the total arc motion to about one-half. To minimise this differential motion, Herr Nobert doubtless used the greatest possible eccentricity of the short arm of the lever, so as to use the smallest motion in arc required for his subdivisions.

The following instruments, objects, &c., were exhibited:—Mr. Beck, "Star" microscopes; Dr. J. D. Cox, photographs of broken diatom valves; Mr. Crisp (1) Bausch and Lomb Optical Company's mirror with diaphragm; (2) simple microscope with "multiplying glass" as the illuminator; Mr. Groves, Cambridge rocking microtome; Mr. Guimaraens, six slides of pathogenic bacteria; Dr. Maddox, slides illustrating his paper; Mr. J. Mayall, jun., model of Gray's water microscope; Mr. Wethered, slides illustrating his paper.

**The Mint.**—The 15th annual report of the Deputy Master of the Mint states that the amount of gold coined during the year 1884, though exceeding by more than a million the amount coined in 1883, was not large, and the silver coinage, which in 1883 reached the abnormal figure of £1,274,000, did not greatly exceed the average. The coinage of bronze, on the other hand, was larger than in any year since 1875, and the colonial coinages executed were unusually numerous. The coins struck during the year 1884 were no less than 34 different denominations, and the total number of good pieces struck was 56,363,301, as against 39,119,714 in 1883, and their value, real or nominal, £3,157, 966 10s. 1d. The good pieces of Imperial coinage consisted of £2,336,513 in gold, £664,433 in silver, and £69,346 in bronze. With regard to the bronze coinage, of the amount issued in 1884, £44,450 consisted of pence, £14,990 of half-pence, £5,895 of farthings, as against £37,590 of pence, £9,350 of half-pence, and £2,830 of farthings in 1883.

## SCIENTIFIC NEWS.

THE death is announced, at the early age of forty-six, of the Rev. R. Bailey Walker, the secretary of the Vegetarian Society, and editor of the *Dietetic Reformer*. The deceased was an ardent supporter of the co-operative movement; but of late years has been identified with the vegetarians.

Mr. Joseph Sidebotham, F.R.A.S., and F.S.A., died on Sunday last, at Bowdon, Cheshire. The deceased gentleman was well-known in Manchester for his scientific attainments, and for the energetic part he took in connection with the Literary and Philosophical Society of that city. He was a founder of the Manchester Photographic Society, an enthusiastic entomologist, and an able astronomer. He rendered Mr. Nasmyth useful assistance when the latter was writing his work on the Moon.

Mr. Alexander Croall, curator of the Smith Institute, Stirling, and author of "Nature-printed British Seaweeds," a valuable contribution to that branch of science, died recently, aged seventy-six.

By the death of Peter William Barlow, F.R.S., the Institution of Civil Engineers loses one of its old and distinguished members. Mr. Barlow was engaged principally in railway construction, much of the South-Eastern system being his work; but he also designed Lambeth Bridge, and that unique device, the Tower Subway. Mr. Barlow had retired from practice several years; but continued to contribute papers to the Royal Society. He had attained the age of seventy-six years.

The trustees of the Lick Observatory, Mount Hamilton, California, anticipate that the great telescope will be ready for use not later than the autumn of 1887.

The Leander McCormick Observatory, attached to the University of Virginia, established at a cost of £13,000 by Mr. L. McCormick, has a telescope of 26in. clear aperture. Mr. Ormond Stone has been appointed director of the observatory, an endowment fund of £10,000 having been provided by public subscription. The observatory is intended for the use of students from any part of the United States who may desire to become astronomers, for which reason the directorship of the observatory is a distinct post from that of professor of astronomy in the university.

Prof. Chrystal will preside over Section A at the next meeting of the British Association, Prof. Armstrong over Section B, Prof. Judd over Section C, Prof. McIntosh over Section D, General Walker over Section E, Prof. Sidgwick over Section F, Mr. Baker over Section G, and Mr. F. Galton over Section H.

The International Sanitary Conference has evidently determined to support the old quarantine system, and that in spite of the fact that numerous vessels are continually arriving in England from cholera-infected ports without bringing the epidemic even when deaths have occurred during the voyage. The *Times* is justified in the remark that "If other nations could show as clean a bill of health, they would be in no such hurry to propose preposterous regulations which are really designed to cover their own sanitary *lâches*."

Attention is being called to the position occupied by Gresham College, the endowments of which are little better than wasted. The lectures delivered there are scantily attended, the most attractive being those on astronomy and music; but the place of delivery being located in the heart of the City, the time fixed (6 p.m.) is too early for those who would gladly avail themselves of the opportunity of listening to an instructive and interesting lecture. The *Times* says the proper City of London College is Gresham College; but the latter, as it is, "has been for centuries, and is doomed to be, a burlesque of collegiate life. Its lectures must be equally dead whether delivered in a dead or a living tongue. Its choice is between becoming something more or something less than it is now. If it cannot develop, it had better cease to be." Sir Thomas Gresham's trust is vested in the Corporation of London and the Mercers' Company: it is time that it was employed in the manner which was intended by its founder. According to the strict letter it is; but the present method would not have pleased Sir Thomas Gresham.

Last week, at the Royal United Service Institution, Lieut. Chisholm-Batten, R.N., delivered a lecture descriptive of the applications of electricity to naval purposes, in which, after describing the benefits of electric lighting on board ship whether in harbour or at sea, he referred to the advantages of firing guns by the current. In the case of a broadside, the explosion was more simultaneously effected than could be done by hand firing; the firing could be directed by an observer clear of the smoke of the gun deck, when the crew was lying out of the way, and it could be effected at any particular moment. Moreover, electricity admitted of ships firing guns with effect even when the ship was rolling, as the circuit could be so arranged that the guns would be automatically fired when the vessel had arrived at a given inclination. The use of electricity to propel, discharge, and fire torpedoes was also illustrated, and the lecturer mentioned its applications in resisting night attacks.

The Arctic steamer *Alert* is now on an expedition to Hudson's Straits and Bay to examine the harbours on the south and west of the Bay, and to report on the condition of the Straits, with the view of establishing a trade route between the Western Territory and Europe. It is doubtful whether the Straits are sufficiently open for more than six weeks in the year.

The turtle-decked, mastless steamer *Meteor*, which was to have crossed the Atlantic in five days or less, is, we learn, to be employed in America for towing purposes, and yet she is credited with having "made most 16 miles an hour" with 140lb. of steam pressure; but that, we understand, was with a strong tide in the river.

A paper was read recently by Mr. V. J. Bouton before the King's College Engineering Society on the "Construction of Locomotives," in the course of which the author referred to the subject of crank axles, and showed by a tabular statement the failures of axles in 1883, pointing out the superiority of steel over iron. He also referred to four-cylindered locomotives, and described the systems of compounding adopted by Mallet and Webb respectively, expressing a hope that compound locomotives would ultimately be adopted on all English railways.

Mr. E. S. Bruce is experimenting with incandescent lamps in translucent captive balloons, and by making and breaking circuit he proposes to flash Morse signals by night. He is to lecture at the Birkbeck Institute on June 10, and will describe this invention.

A "telpher" line is to be erected at the Sussex Portland Cement Works at Heighton, near Newhaven. The line will be a rod of steel ·75in. in diameter, resting on cast-iron saddles raised on the average about 12ft. above the ground. The supports will be about 22 yards apart.

The Bartholdi statue, when erected in New York Harbour, will be lighted at night by electric lamps at the base, the rays being cast upwards by means of strong reflectors. From the uplifted torch there will be thrown a vertical beam of light, intended to reach the lower cloud stratum, from which it will be reflected far out to sea. The idea of rays streaming from the diadem has been abandoned.

The experiments made by the National Fish Culture Association to acclimatise the American white fish (Coregonus albus) have met with gratifying success. A number of those hatched at South Kensington were transferred to the ponds at Delaford, where they have thriven well for the last two months.

**The New Chicago Clock.**—A new clock of great size, weighing 10 tons without the bell, which weighs over two tons more, has just been completed in the clock tower of the Board of Trade Building, Chicago. The materials employed in its construction are iron, steel, and bronze. The pendulum alone weighs 750lb. The works, which are on the plan of the great Westminster clock, are divided into a time train, a hand train, and a striking train. These trains are separate machines, resting side by side, on separate frames. Each of these trains is actuated by a separate weight, and the three weights together weigh 3,500lb. The hammer that strikes the bell was to have weighed 120lb., but a patent hammer weighing only 80lb. has been preferred. The clockwork is below the dials, which are 10 feet 10 inches in diameter, and the bell is above them, and 250 feet from the ground.

# LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

*All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. Passmore Edwards.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

## THE FOCAL LENGTHS OF DIFFERENT FORMS OF TELESCOPES — EVOLUTION—PREHISTORIC MAN—JUPITER —THE LATE REV. PREBENDARY WEBB — ZETA HERCULIS — THE SEPARATION OF DOUBLE STARS— THE NEW TIME—LONGITUDE BY MOON-CULMINATING STARS.

[24307.]—I am sure that Mr. E. M. Nelson will forgive me for pointing out, in connection with the dictum of mine which he quotes in his article on p. 247, that it was given with reference to the achromatic astronomical telescope, an instrument differing wholly in principle and construction from the Galilean form, which is that employed in the ordinary binocular field-glass. In the achromatic an image is formed by the object-glass, and magnified by the microscope which we call the eyepiece. In the Galilean telescope the rays which traverse the objective are intercepted by the concave eyeglass before they have formed any image at all, and the only effect of that eyepiece is to render them more nearly parallel, or perhaps it would be more rigidly correct to say, less convergent. Hence, the only limit to the approximation of the eyeglass and object-glass in this form lies in the violence of the curves necessary to produce any sensible increase of power when they are too close together. Be it carefully noted that I am not writing this for Mr. Nelson, who is as familiar with the optical facts and theory as I am, but for many who will, I am a little afraid, rather misunderstand his reference to what I said.

"Pre-Adamite" (letter 24257, p. 258), may, with considerable advantage, study Chapter XV. of Professor St. George Mivart's classical work on "The Cat."

"Dens" (reply 54825, p. 262) should certainly obtain, and carefully read through, Joly's "Man before Metals," which forms Vol. XLIV. of the "International Scientific Series." The practice of making oneself acquainted with facts before theorising upon them can hardly be too highly commended or sedulously followed.

The part of *Ciel et Terre* for May 15th contains the first part of a very interesting paper on the physical constitution of Jupiter, by M. J. C. Houzeau, the late Belgian Astronomer Royal. After a précis of the history of Jovian discovery, M. Houzeau goes on to give an account of the salient features of the planet, and of the hypothesis which was formerly advanced to explain them. This in effect referred the belts so familiar to all observers to the presumed analogues of or parallels to our trade-winds in Jupiter, and assumed that they were gaps in the illuminated atmosphere of the planet through which its darker body became visible. M. Houzeau, of course, has no difficulty in showing the untenability of this idea, and in demonstrating that Jupiter is at present rather in a quasi-solar state than in one at all resembling that of our own earth. All interested in the physical structure of the members of our solar system should obtain and read M. Houzeau's essay. I shall myself look out curiously for the second part of it. The first instalment, on which I am commenting, is illustrated by two chromo-lithographs from drawings of the planet, made by MM. L. Niesten and E. Stuyvaert, by the aid of the 15in. equatoreal of the Royal Observatory at Brussels with a power of 360.

It was with most sincere and unaffected grief that I read the paragraph with which your "Scientific News" begins this morning. Few, indeed, are the British amateur astronomers who will not feel that in Mr. Webb they have lost a personal friend; albeit they may never, in this life, have seen his face. It would be hard to overestimate the extent and value of his labours in inspiring and developing that taste for observational astronomy which has so enormously increased in this country, during the memory of the majority of those who will read these lines. The late Admiral Smyth, by his "Celestial Cycle," did much in this direction in the days of our fathers; but where he addressed scores, Mr. Webb has appealed to hundreds, and perhaps even thousands, by his more recent and compendious work. It would be almost an impertinence to speak in his praise to those who had had the privilege of his personal friendship or acquaintance. His holy, simple, and beautiful life may not be dwelt on here. Emphatically of him may be said, however, that "he being dead yet speaketh."

I have to thank Mr. Sadler for his notice of my question in the latest of his invariably instructive letters (24270) on p. 276. I must certainly make another attempt at ζ Herculis. As I have seen it distinctly double in former years, I cannot imagine why I recently failed to do so, especially as I employed a telescope which shows the *comes* to δ Cygni—a really difficult object with such an aperture. (Since writing these lines I have easily and distinctly divided ζ Herculis in twilight.)

In reply to letter 24272, p. 276, I may say to Mr. Nelson that cæteris paribus, the diameter of a star disc does vary as the aperture; and that Mr. Knott's measurements were made by stopping down his 7·33in. Alvan Clark refractor. The focal length of an objective has nothing whatever to do with its separating power, which is strictly a function of aperture. In connection with this, by the bye, I should like to remark, with reference to the concluding paragraph of Mr. Sadler's letter, that Dallmeyer's formula for the separating power of an achromatic objective was $\frac{4\cdot33}{\text{aperture in inches}}$; though, of course, even this would not explain Dawes's astounding optical feat which he there records. What I meant by the passage quoted by Mr. Nelson was simply this: that when the images of the components of a double star were in contact as formed by the object-glass, it was no more possible to divorce them by any subsequent amount of amplification by the microscope which we call the eyepiece, than it would be to convert a figure 8 into two noughts, thus: $^{\circ}_{\circ}$, by a pocket lens, be it ever so powerful. Theoretically, star discs should increase pari passu with the power; but I am unaware whether any experiments have been instituted to test this. Sir William Herschel's micrometers were, I should think, not sufficiently delicate for such very refined measurements as these.

May I venture to point out to "Conservative" (letter 24294, p. 282) that I have never, either in these columns, or out of them, advocated the astronomical change of time until such date as the not particularly rapidly moving department in Verulam Buildings shall be in a condition to introduce it into the *Nautical Almanac*. I do not think that astronomers, pure and simple, would be materially troubled by the change, the correction for it being a constant quantity; but the muddle and confusion it would introduce in our mercantile marine are awful to contemplate. Jack's *Nautical Almanac* says that the day begins at noon, and just so long as the aforesaid Jack, with his delightful old rule-of-thumb method of computing his quantities, finds this statement definitely made, just so long will he conduct all those computations upon supposition. If the law says one thing and the *Nautical* another, calculations will be fearfully and wonderfully made with a vengeance! This, however, will not prevent the division of the civil day into 24 hours, commencing at midnight, being made obligatory.

In the absence of the context it is not easy to answer query 56702 (p. 289) categorically. When the places whose difference of longitude is to be determined by the observation of moon culminating stars are at any considerable distance apart, inasmuch as the moon's motion in right ascension is not uniform, the simple proportion embodied in the formula no longer exists, and the increase of the moon's R.A. between the two given meridians, must be obtained by interpolation. The A. of Simms's table seemingly represents the factor by which the observed hourly change must be multiplied to render the proportion practically correct.

**A Fellow of the Royal Astronomical Society.**

## A CORRECTION.

[24308.]—Would you kindly correct a statement in your report of the Special General Meeting of the R.A.S.? I said at the meeting that, owing to a *printer's error*, the wording of the resolution would have to be altered, &c. This was wrong, and I should have said, though much care had been given to the wording of the resolution, it would have to be modified in the word *Lists*.

As it would appear that I seemed to cast an imputation of carelessness upon the honorary secretaries of the society in not revising the proof of the circular, may I ask you to insert this explanation in your next issue, with the assurance that nothing was further from my thoughts?

Haigh Hall. **Crawford.**

### THE ASTRONOMICAL SOCIETY.

[24309.]—My attention has been called to an error in your report of the special general meeting of the Royal Astronomical Society on the 8th inst., which I beg to correct.

The exact wording of the alteration of By-law 12, finally handed in by Lord Crawford and agreed to by the meeting, is: "Any list addressed and posted to the scrutineers of the ballot by any Fellow not present at the meeting shall be accepted if duly verified by the signature of the absent Fellow on the envelope."

**Ed. B. Knobel, Secretary R.A.S.**

### ASTRONOMICAL.

[24310.]—As some discussion is going on *re* ζ Herculis, I may say I found it very easily visible on May 23 with 4in. stop, and am quite sure a smaller aperture would do it. Σ. 1932 being again within my range, I tried it, and found it easier than it appeared last year being about the disc of larger star clear apart. The opinion of its extreme closeness, given last year, must therefore be a mistake caused by unsteady air. $\mu^2$ Boötis I find is now clear disc of larger star apart, P.A. about 100° ±. η Coronæ the discs are just clear. ζ Boötis I could not see divided, the discs being in contact and angle 285°. Of course, with so close a star, greater steadiness of air is required than I ever got to measure P.A.'s with any exactness. γ Coronæ appears elongated, and also 25 Canum. I have totally failed to see *comes* of τ Boötis.

**Edwin Holmes.**

### ζ HERCULIS.

[24311.]—Having read the letters in the English Mechanic about the visibility of the companion of ζ Herculis, I last night, May 29th, turned my 8½in. reflector, with full aperture and power 190, on the star; I suspected the companion, but could not be sure, the power being too low to form a clear disc. I at once put on 700, and the two stars stood out well apart; I then tried 300—companion well seen; the aperture was then reduced by a 6in. stop, still well seen; next a 5in. stop was tried, and the smaller star was now visible as a brighter point on a broad diffraction ring. With a 4in. stop I could just detect it, knowing where to look for it, but I should not have seen it had I looked for it first with that aperture; but the reflector, thus stopped down, was under the disadvantage of having too large a flat (1½in. diameter) for this contracted aperture. I believe a 4in. refractor would have shown the companion last night.

Shaftesbury. **T. Perkins, M.A.**

### ORIGIN OF COMETS.

[24312.]—As this problem has yet to be solved, I may venture on starting what, as far as I know, is a novel idea, and I do so with some little confidence, since it seems to fulfil certain conditions.

Space is intensely cold, and if there is moisture in space, there would be ice in space. Why should not a comet be an iceberg, which, from being more or less transparent, would pass the sun scarce affected by his heat?

Meteors are of earthy substance. Why should not comets be of watery matter?

June 1st. **J. D. S.**

### COMETS AND METEOR RINGS.

[24313.]—My remarks, as summarised in the report of the last meeting of the Liverpool Astronomical Society (English Mechanic No. 1,052, p. 254), do not quite convey the meaning I intended. My criticism of Mr. Sutton's paper was not suggested by any desire to endorse the theory propounded by Mr. Proctor, that the various groups of elliptic comets were originated by eruptions from the larger planets of the Solar System near whose orbits their aphelia are congregated. My purpose was more to show that a comet or mass of meteoric particles revolving in a closed orbit might be expected to form a ring in process of time. The resolution of a comet into a continuous stream of meteors may, of course, be a work of many ages, and brought about by natural processes, all of which will hardly have been sufficiently considered in the inquiries hitherto directed to this question. If the individual fragments of the group were in orbits of much the same shape, the differences in perihelion distance would mean a difference of periodic time (*i. e.*, the interior particles of the orbit would constantly gain ground on the outermost particles), and thus at each revolution the relative displacements would go on lengthening the mass until the complete ellipse is formed. This accords with what I mentioned, that comets might possibly have had a derivative source in planetary eruptions, and as your able correspondent, "W. C. E.," remarks in letter (24274), p. 277, there is nothing to absolutely negative that supposition; "but whether the total mass of meteors, say, in Tempel's meteor comet, might not be so great as to render its planetary origin improbable, as Mr. Sutton supposes, it is not easy to say." I think that Swift-Tuttle's comet III., 1862, and its associated system of meteors (the August Perseïds) forms an instance even more significant than that cited by "W. C. E." This stream is vastly greater in breadth, is more evenly distributed, and extends to a far more remote distance than the Leonids of Tempel's comet. Its width must be some 35,000,000 miles, and its aphelion distance lies far beyond Neptune, while the aphelion of the Leonids is just outside Uranus. The latter, though forming a continuous stream, are thickly grouped near their derivative comet, and are very thinly represented along the greater part of the orbit. In the case of the Perseïds, we have a very rich shower annually, and this, taken in conjunction with the exceptional breadth of the system, and its distension to a very remote distance, prove it to be one of immense extent, and of such character to suggest an origin in some other cause than that of a mere planetary eruption. It is true that the aphelion distance (48·6) of this stream and its allied comet is situated much beyond the orbit of Neptune, and does not, like the comet of Tempel, and many others of shorter period, nearly coincide with the distance of a known planet; but I suppose there is no material reason for assuming this to mean a difference of origin, especially as there is a doubt as to the exact time of revolution.

The April meteor system, which, if really pursuing the same orbit as Thatcher's comet I. 1861, has a period of 415·4 years (Oppolzer), and at the aphelion distance (110·3) is at an enormous interval outside the bounds of our system, unless, indeed, the supposed trans-Neptunian planets of Prof. Forbes extend its limits to an almost inconceivable degree. The meteors from Lyra form a very narrow stream, and there is evidence of its continuity; but observations must be maintained for several centuries before the fact can be demonstrated.

As to Biela's lost comet, and the slow meteors of Nov. 27th, radiating from Andromeda, it is questionable what has become of these phenomena. Next November ought to definitely settle the point whether the meteor shower has been so disturbed by planetary perturbations as to have finally withdrawn from the region of the earth's orbit. On one of the nights during the last week of the ensuing November, there may be a splendid display of these meteors, as the conditions are very favourable; but, of course, everything depends upon whether the condensed part of the stream has preserved the same orbit since the observed *rencontre* of Nov. 27th, 1872. For myself, I do not anticipate any great revival of the shower, my opinion being, after the negative results of 1879, that the orbit has been much changed.

Mr. Proctor has ably discussed the phenomena bearing upon his hypothesis of planet-born comets; but it is difficult to comprehend the matter in its entirety, and to give proper weight to all the elements affecting the question. It is certain that before any hypothesis can be definitely accepted, there is a pressing necessity for further observations, especially of meteor showers and their varying richness from year to year. The successive returns of periodical comets also require much public investigation, especially as regards their probable decadence, and the orbital and physical changes to which they are commonly subject. Questions affecting their origin and the probability of their dispersion into meteor orbits hardly admit of satisfactory settlement, as nearly all the evidence we possess concerning them is of comparatively modern date; much of it, indeed, quite recent. **W. F. Denning.**

### SUNSPOTS.

[24314.]—I observed the extraordinary, large spot on the sun's disc on the 25th. It was a beautiful sight. Since the 23rd it had thrown a bridge across the centre, and one half had the appearance of an Indian's club, broad at the top, and tapering to a blunt point at the bottom. The penumbra was unusually striking, as there were several streaks sloping towards the nucleus. To me they appeared as though they were portions of the photosphere which were being sucked or drawn inwards, which forced the impression on my mind that it was a tremendous whirlpool. At one time I noticed a violet hue encircle the whole of the spot, but it did not last more than four seconds. I was using a ruby-coloured sun-cap, but cannot account for the violet tinge, as I have never seen such a tinge of colour on sunspots before. Was it the fault of the eye or the telescope? Those of your astronomical readers who took holiday from their observations on the 25th missed a treat. The spot was visible to the possessors of nothing but a piece of smoked glass on Saturday, the 23rd.

5, Rownsley-street, Leeds. **D. Booth.**

### THE MOON'S DISTANCE.

[24315.]—Is it possible to explain to a non-mathematical reader the way in which the distance of the moon is ascertained? If, for instance, a moon or other globe subtends a given angle, that alone would not give its size unless the distance were also known; nor vice versâ, because a body at twice the distance if twice the size would subtend the same angle. In the case supposed neither size nor distance can be predicated, and we need one of these, in addition to angular measurement, to ascertain the other. **Essex Clod.**

### THE CASSEGRAIN.

[24316.]—I am glad to see the letter of "A. S. L." (24278) upon this subject. It wants looking into in a thoroughly mathematical and practical way, and settled once for ever—i.e., as to whether a Cassegrain with a spherical convex and a suitable elliptical concave will give definition equal to a parabolical Newtonian, or near enough to it to satisfy those who prefer the Cassegrain form of reflector. To this end the suggestion of "A. S. L." is very good, it being practical, if only our mathematical friends will calculate the eccentricity of the ellipse, or give us a rule to do it. Then we could put the pinhole, as it is called in testing, in one focus, and the shutter in the other focus, and work our concave so that the shadow comes on all over alike and goes off the same; or we could use stops, and see if all the rows were the same in focus. Thus we should get the ellipse absolutely; or if the further focus would be too far off the concave to be tested in our testing chamber—in my case this is my cellar, where I have about 30ft. of testing space—then our mathematical friends could calculate for us at centre of curvature (so-called), or give us a rule to do it ourselves. The aberration of the zones of the ellipse. I divide my mirrors into six equal parts; five I calculate and test, and the centre we can ignore, as the hole would be there. Then we could test in a space double the focus for parallel rays of the ellipse. All this would be as easy as the testing of the parabola for a Newtonian. Now, I am not much in favour of the Cassegrain, though I believe it is a far more practical form than the Gregorian. Nevertheless, I should be glad to help anyone in the testing of the mirror of either form, and I hope all will feel free to make use of my services. The cost will only be the carriage, and then certainty will be obtained, and the value of the Cassegrain form with a spherical convex and *suitable* elliptical concave will be proved once for all, and it would be a real kindness to all after comers to settle this question, and I wonder that those who like this form of reflector do not set about it in this way, instead of, as "A. S. L." justly puts it, "At present a tedious process of trial and error has to be gone through till an approximately correct result is obtained, more by chance than by knowledge." It seems strange to me that those who spend a lot of money upon this experiment should waste their time in this tedious process when a certain and quick mode is at hand. I hope our friends who like the Cassegrain form will not be offended at my remarks, as they are not intended to grieve, but to urge to a saving of time and money too, and to a certain way of settling this vexed question.

I feel sorry, like "A. S. L.," that Dr. Royston Pigott's articles on the Cassegrain are not continued. I had hoped the Doctor would have given us the result practically of his experiments on his large Cassegrain, such as to the definition, &c., and as to whether he thinks it will ever equal the Newtonian. There are great advantages, I admit, in the Cassegrain, but there is one disadvantage I have noticed in all I have examined, and I am sure "A. S. L." and others, and myself as well, would like to know from the Doctor how far he has succeeded in overcoming it—viz., the getting rid of the stray light that enters the eyepiece with the light reflected from the convex. The light passing by the convex from the sky near the object under observation will enter the eyepiece at very nearly the same angle as the light from the convex, and I have always noticed the absence in the Cassegrain of that dark background that enhances the value of the Newtonian form. May we trouble the Doctor for information on these points? I am sure "A. S. L.," who from his previous letters evidently prefers the Cassegrain, and others, I have no doubt, would feel greatly obliged to the Doctor for anything he can give us on these points. **H. A. Wassell.**

Addenbrook Villa, Love-lane, Stourbridge.

### HIGH POWER OPERA-GLASSES.

[24317.]—On the day on which "Montmartre's" letter appeared I sent an order, with cash, for one of the powerful opera-glasses. The cash was retained; but a request was sent for the ticket number, which I forwarded to "Montmartre," who had given his address, begging him to do the needful. In consequence, I had one of the glasses within a week of the announcement; but any other friend's ticket number would have done as well. Indeed, at the stores at which I have had tickets, they seem pretty well satisfied with any number of about five figures. I do not remember figures well, and, when asked, I boldly give the number as well as I can remember it. It may be right, or it may be wrong; but it always seems to be satisfactory.

I like the glass very much indeed; but I have not used it inside a building, where I think it would be most useful. I lent it to a lady, confined to her room for some weeks, and it has been the greatest interest and delight to her. "I could see the flowers coming out as well as if I was in the garden" was her testimonial, and, I think, a pretty graphic one.

C. B. D.

---

## POWERFUL OPERA-GLASSES.

[24318.]—I SEE by G. Dickson's letter in last week's "E. M." that he cannot obtain in England the high-power opera-glasses alluded to by "Montmartre"; and as other readers may like to test for themselves these much-talked-of glasses, an optician in London has obtained a set of the different sizes, and they are now on view at the address advertised on front page. These can be tried side by side with glasses constructed in accordance with the results of an experience extending over a period of 30 years, not in a limited way by merely looking at letters of various size at comparatively short distances, but in the field and at the seaside, at such places as Wimbledon, Sheeburyness, Altcar, &c., where the atmosphere has a curious effect on glasses disproportionately powerful.

I cannot too strongly endorse "Experience's" recommendation to "try before you buy" such (to my mind) unsatisfactory glasses, for they are anything but pleasant to use with such a limited field of view, and, with the exception of the large one, have nothing remarkable to commend them in the way of power, and the latter is behind, in power and definition, the first size new form of wide-angle binocular telescope, which is less than half the size, and therefore more convenient.

I was very glad to see that an authority like Mr. Nelson laid great stress, in his article on Terrestrial Telescopes, in the "E. M." of May 21st, on the importance of considering light and field before power, and what holds good with the hand telescope is doubly important with a binocular, which generally has to be used quickly, and is required primarily to give clearness and an extensive view of landscapes or groups on a stage.

New Wandsworth. G. R. Baker.

---

## THE MICRO-OBJECTIVE.

[24319.]—SELECT a bit of the clearest plate-glass about ⅛in. thick, not less, and cut it ⅝in. square; nibble the corners away to make it round as possible, and fix it with sealing-wax on an iron chuck. Grind one side to an inch radius curve, reverse it, grind the opposite side to the same curve, and we have 1in. focus biconvex of ½in. diameter.

The iron chucks I use are made of any convenient bits of round iron, screwed to go into the lathe-nose, or occasionally I run it in a drill-chuck; but I prefer the former plan.

The chucks must be turned true and flat on the face, and be the same diameter as the lens when finished—in this case ½in.

The roughly-shaped bit of glass may be made approximately lenticular by grinding on a lap with emery, or on a grindstone, and finished in the mould by which I mean the true grinder.

For mould I generally use a piece of glass—common stuff if to make a simple lens; but if I make an achromatic pair, I hollow out a piece of flint glass and use it, thereby "killing two birds with one stone."

The piece of flint glass should be at least ⅝in. diameter, and be secured to a chuck like the crown lens, and when the two curves are true in figure they may both be perfected in the fine grinding by running the convex and concave in the lathe alternately until both are perfectly fined for polishing.

The lens in the hand is not to be kept still and concentric with that in the lathe, but be moved over its surface with a circular motion of the hand through 30° or 40° of arc in all directions.

The finest grinding can be done with washed emery only, instructions for getting which have appeared in the papers on specula-working.

To measure the curves of small lens, cut a hole in a piece of zinc with drill, rimer, centre bit, or any available tool of the required radius, cut the piece in two with shears, and snip off sufficient to leave about 120°, which use as gauge applied to the convex, of which the concave should be a counterpart.

The concave curve must be ground so as to extend to the edge of the disc of glass, so that $\frac{1}{16}$ of the polished curve may be ground away afterwards, for that much of the margin will be faulty and useless.

The convex will also lose about that amount in grinding, and if it be desired to get a lens which will be good to the edge, and also to have that edge as thin as possible—a knife edge—the surface first finished must be supported by a glass holder (instead of iron) ground to fit it; then the second lens surface must be ground and polished as desired (holder and all), and when finished and removed all marginal errors are in the holder; but the lens is perfect to the edge.

The best material for these holders is stout glass tubing, like steam-gauge tubes; there being no centre, they are soon ground out on the end to fit the curve of the lens.

The figures will make all clear about the removal of faulty margins; but the concave must have its plane surface made before its margin is removed. I will attend to the plane faces in my next paper.

In the figures the outline shows the glass circle; the shaded parts show what remains as a lens when the other part has been removed. I have used a deeper curve in the Figs. than would make our lens, as it shows the process better. Figs. 3 and 4 are on the iron chucks, and 5 on the glass tube.

FIG. 3. FIG. 4. FIG. 5.

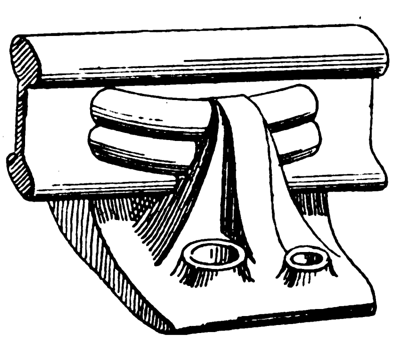
## CRANK AXLES—ELASTIC KEYS.

[24320.]—"LOCOMOTIVE," p. 235, is quite right in his idea that permanent way should be "elastic." Such a system is good and practical, and is employed experimentally, being known as "The Steen Chair and Spring Key System," and the following sketch and description will, I trust, interest "Locomotive" and your railway correspondents. The difficulty of permanently holding rails in place is a matter of such general knowledge, that the solution of the problem has occupied a host of inventors, more to the profit of the Patent Office than to their own benefit, and wood keys continue to be very generally used, despite the various drawbacks inseparable from them. The nature of the above mode of fastening will be understood at a glance from the annexed drawing. The fastening consists of the strong curved steel spring formed in the centre to suit the inner side of the horn of the chair, while the ends press against the web of the rail. If a special form of chair be used, like that shown, the contact surfaces of the spring key, and its abutment on the chair, would be so shaped as to combine convenience and cheapness of production *with secure locking*; but the spring is, of course, applicable to any ordinary chair to the shape of which the bearing of the spring can be adapted. The latter has sufficient elasticity to allow of its being driven into place, and it can be forced out when desired; but the form adopted and material used insure the rail being tightly held at each end of the key, while the middle is held tightly against the chair horn. It seems to me that this arrangement gives just that elasticity which seems to be required to save axles from the "pinching action."



Midland.

[24321.]—I HAVE been much surprised at the statements made by various correspondents *in re* crank-axles. In the first place, it is news to me that cranks are made the wrong way of the grain, and it is also the first time I have seen the statement made that they mostly break across the web. I could fill a page of "Ours" with sketches taken from broken cranks, not one of which had so broken; and as to the twisting business all I can say is, that if a smith made a crank in the manner described (grain wrong way and twisted), his first would be his last (for me), at any rate. And I think loco. superintendents and managers are too wide awake to allow such rubbish to be palmed on to them. During an experience extending over more than 20 years, I have never seen but three cranks that had been twisted, and they were all one make, and were carefully wrapped up in tar cloth and sent back again, with a statement of their faults, and a request that the firm should not send any more cranks so made; and, indeed, they did not receive any more orders, in consequence. But that is twenty years ago. In a properly-made crank there is no grain, for it is made out of the best-use iron, and the various parts are faggoted and forged under the steam hammer until it is impossible to find which way the grain is; or, in other words, you could not find a way in which the iron would break rather than another. I have myself cut pieces from a crank and bent them into a ring cold, and yet they showed no sign of cracking; and the slabs of iron removed from the crank throws (in the slotting machine) have been subjected to severe tests to see if they were weaker one way than another. And, further, I witnessed some tests that were made of cranks that had been running, and were broken under the steam hammer, and only one out of some six or seven, broke across the webs; then as to twisting, there was not the slightest necessity for that, as each throw was built up and welded in its proper position.

And now for periodical examinations. I must say I have the greatest faith in these if done by experts, or men who know what they are looking for. The Midland Railway Company have long had these systematic inspections and with good results; and I say it to their credit, they take every precaution to prevent accidents through breakages; but I remember an instance which will show that flaws are not always to be seen. I was examining a crank and I felt a strange presentiment that it was not sound, and after spending double the time on it that I did on others, I got a powerful glass to it, but not the least sign of flaw could I find, and yet it broke the next trip but one; it broke across the web. I most certainly recommend hoops; the G.N.R. used them years ago, and the M.R. are using them of late; an engine will sometimes come home with the hoop when she would have had to be fetched home if she had not had it.

In conclusion, I should like some of our practical readers to take up this question, and if there are any crank makers among them, let them speak out, and I am sure good will be done by so doing: but the worst of it is that a great many who write are not practical, and hence a deal of chaff and but little wheat.

Original Lockstitch.

---

## LATHE MATTERS.

[24322.]—IF a screw has been cut with a milling tool, and finished up with a revolving lap, made in shape to conform to the curve of the thread, the surface to the eye of an expert using a magnifier will indicate such a mode of finish. If this is a true method, there is no need to disguise or alter it by any after-operation.

In this discussion, when it has been shown collectively that there is no reliable basis of truth in the conditions, and that the practice is productive of error, the resource is to seek for inconsistencies in verbiage. In this I have not acquiesced in mandrels with soft noses, but have advocated hard ones, and would have no other. I agree with "Vulcan," that with a special arrangement hardened mandrel noses, if required, can have their screw threads ground to form. I have a frictionless arrangement for screw cutting that has now been in constant use for several years that will do this perfectly, working alternately backwards and forwards, as there is no backlash. I have long promised to publish this in the "E. M.," but as a set of drawings to scale would be required, I have not been able to spare a day to make them, but I will endeavour to redeem my promise shortly. I do not see any occasion to carry remarks on screw threads formed with revolving cutters any further. The original error is sought to be smothered and hidden by a mass of unreadable "terminology" and endless repetitions, absolutely nil in relation to any practical results.

I may inform Mr. Hines that my large 10-ton screw-cutting lathe had reverse hardened steel cones and collars. The mandrel may, as he says, have been of Yorkshire iron, casehardened, but both in the nose and cones it was file-proof. When running at a high speed during polishing work, the mandrel would sometimes jam instantly and stop without warning. I therefore drew it out to see if anything had gone wrong. The cones and collars were as hard as could be, with a superb mirror-like surface.

As to the gross of mandrels that a competent workman could make so that when screwed into a test chuck, the free ends would run quite true—surely Mr. Hines can do this. If not, of course he is entitled to one vote against its practicability. An error might arise in the final hardening; but I do not admt that with proper precaution this need occur.

The Berlin lathe-makers that I referred to are not "unknown," but are in an extensive way of business, and any young mechanician who can manage to make a start with a lathe of the first maker, complete with all its clever milling and wheel-cutting arrangements, which specially adapt them for his work, considers himself set up for making a home living. I much dislike anything in the way of indirect or gratuitous advertisement. When I stated what I knew to be a fact—that certain lathe-makers used diamond turning tools for cutting hard steel, I first met with a flat contradiction from one whose knowledge in the matter is shown to be nowhere. I was then challenged to name any maker; then accused of making paltry excuses. I am next taunted for having done so. Very liberal-minded, all this. Mr. Hines knows nothing practically of the use of diamond cutting tools, and is therefore no authority. Their application will be an increasing one. From the ever-enduring ruby file for hard steel, known to the watch-pivot turner, we have advanced to the wheel-cutter furnished with shaped ruby teeth used by the Waltham Watch Co. (first noticed in a recent leading article in this journal). The first cost of this cutter would be very great, but it would probably operate for years without the necessity of resharpening, which, from its frequency, makes the steel cutter a troublesome tool to maintain. With these remarks I leave Mr. Hines in the position that his own letters have placed him.

**F. H. Wenham.**

[24323.]—"Vulcan" is quite right in saying that, what he dignifies by calling a "diagram" on p. 237, Fig. 3, is misleading. One side consists of a considerable blot, and the other, for the most part, of a very crooked line. I dare say they are just as I drew them.

The groove should have been a very open V, inclosing about 85°, with perfectly straight sides for about two-thirds of the depth of cut, and rounded for the remaining one-third. The Figure 2, of a less angle, on p. 259, shows better, being something superior to such a very rough sketch. I have no recollection of ever calling these grooves U-shaped. On p. 237 I said "one," that is, a V-groove, "with a curved bottom," in contradistinction to a "sharp V groove" in the previous line.

I should have been suspected of magical arts had I more precisely stated on p. 237 what I meant by bending the file the reverse way. Say you take a long file of triangular section. Heat the middle of its length, leaving the ends cold; bend the hot part one complete turn round a cylindrical bar, leaving the ends parallel and one V-edge inwards; you would then get a tool which would assimilate in its action that of the teeth of a screw die, and from the very method adopted in forming it would come out ready provided with winding surfaces. A straight file applied to any but a very low pitch of thread would require twisting first. I believe that sticks of wood wrapped in glass paper are used in the manner of files in smoothing the so-called "Elizabethan twist" work.

As I had the pleasure of a visit from Dr. Edmunds on Whit-Monday, and we occupied our time in discussion and actual cutting of screws, and find that we are much more of agreement than either of us supposed, I shall follow "Vulcan's" lead and drop the matter here. I will leave one of the results of my screw-cutting at the Editor's office for anyone who wishes to look at it. "Vulcan" accurately describes the curves in his 9th paragraph, p. 281.

**J. K. P.**

## THE PRODUCTION OF SCREW-THREADS.

[24324.]—Your correspondent, Dr. Edmunds, invites me (24263) to reconsider the sketch I sent you, illustrating one of the defects of the system of cutting screws with revolving cutters, and which you were good enough to publish on p. 236. He still maintains that there is no such distortion.

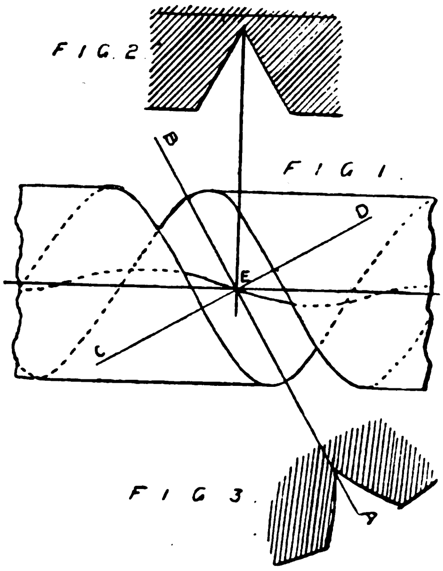
I now send another example, which will, I trust, illustrate the matter more clearly.

Fig. 1 represents a cylinder with a screw-groove cut on it, Fig. 2 being a section of the groove taken horizontally. Line A E B is then, as before, the angle at which the cutter would be set to cut such a groove. C E D is then the cutter's axis. I now confidently assert that Fig. 3 is an *exact representation* of a section of the groove taken along line C E D, so that the point E passes through the axis of the screw. In my previous sketch I slightly exaggerated the distortion for the sake of clearness, but I have not done so here.

I say again that for this reason a revolving V-cutter, or lap, the sides of the V being straight lines, used in the way Dr. Edmunds has explained, *must* produce a screw-thread with hollow sides.

Fig. 3 is obtained, not by any mere guesswork, or viewing of the matter in the mind's eye, but by the ordinary rules of practical geometry and projection, which enables one, when three views of a body are given—viz., side elevation, end elevation, and plan (drawn, of course, in parallel projection), to obtain any other possible view or section with as much accuracy as if the result of a mathematical process.

I thought of sending you, Sir, a full description of the method of obtaining Fig. 3 by projection, but found it would take up too much of your valuable space, and involve a good deal of engraving. Most of your readers, too, are probably acquainted with the principles involved, and so able to work it out themselves, which I would invite any of your readers interested in the matter to do; and I submit, Sir, that it would be only fair to all concerned, if any of your correspondents, who may think of writing to say my figure is incorrect, to satisfy themselves on the point before doing so, either by drawing as indicated above, or by means of a carefully-made model, as the mind's eye is hardly to be trusted to arrive at a correct conclusion without assistance.



The distortion shown varies in amount as the tangent of the angle of the pitch, and, therefore, would not be great in screws of large diameter and small pitch, but even then would be enough when taken in conjunction with the other error, explained by "J. K. P.," to condemn the system, except for use in cases where great accuracy is not required, and where, from some peculiarity of the work, the ordinary method is not applicable, as, for instance, cutting screws on glass.

May 25. **Canmore.**

## CUTTING SCREW-THREADS WITH A REVOLVING CUTTER.

[24325.]—If I may be allowed a few words on this much-debated subject, I should like to remark on "Hadah's" letter, p. 235, that it really explains the whole matter with a clearness and simplicity of language which some of us would do well to try to imitate. The surface of a V-thread is a "ruled surface," i.e., can be generated by a straight line; there should, therefore, not be much difficulty in settling (theoretically, at least), how a lap or cutting-wheel, which has also a "ruled surface" generated by a straight line, should be applied, so that screw-thread and cone shall touch each other only along one straight line. Imagine a cylinder having the curved line called a helix traced on its surface, and let an isosceles triangle be moved along this cylinder in such a way that its vertex moves along the helix while its base moves along the axis of the cylinder. Then the triangle describes the surface of a screw-thread, not such a one I imagine as would be of any practical use, but still a screw-thread of a certain kind, and one that could be cut by a lap or wheel having its axis parallel to the axis of the cylinder. With such a thread the section given in "Canmore's" letter, p. 236, Fig. 3, would be correct, so far, at least, as this, that the sides of the V in a section so taken would be curved, and not straight.

Now let the triangle be turned about its axis, and, instead of moving with its base along the axis of the cylinder, let it so move that the axis of the triangle is, as before, always at right angles to the axis of the cylinder—the vertex of the triangle, as before, always on the helix; the plane of the triangle always at right angles to the helix. The triangle now describes an ordinary V-thread, to cut which the lap or cutter must have its axis "at right angles to the rake of the thread," as "Hadah" puts it; in other words, the axis of the cutter must be parallel to the plane of the describing triangle.

**W. A. S.**

## ASTATIC GALVANOMETER.

[24326.]—The galvanometer described below is suitable for use with a Wheatstone's bridge. If properly made, one cell will give a deflection of 20° and upwards through 1,000 ohms. The sizes given are those of the smallest I make; but the sizes of all the parts, except the needles and coils, may be increased with advantage.

A round wooden stand, 8in. diameter, ½in. thick, has a groove turned in its upper surface to hold a glass shade, 7in. high and 4in. diameter. Three levelling screws are next made. Three pieces of brass rod, 3/16in. thick, have a screw-thread cut on them, and are forced tightly into three wooden heads. The screws work in three equidistant holes drilled and tapped near the edge of the stand, and opposite to the brass support described below. Then the bobbin: Get three pieces of wood, 2¼in. long and from ¾in. to 1in. wide. Two of the pieces are ¼in. thick, the other 3/16in. thick. Two ¼in. holes are drilled in each in the middle of the width, the centres of the holes being 1¾in. apart. In each of the thicker pieces a slot is made almost joining these holes, 1¼in. long, ¼in. wide. Two rods of wood, 1¾in. long, ¼in. diameter, are pushed through these holes and glued. The two thicker pieces are on the outside, the other in the middle. There are thus two spaces, ½in. wide, between the inner pieces and the outer piece. These spaces are filled with 20 or 22 silk-covered wire. Leave about 6in. of the end for connection. Fill one space first, then pass over, and fill the other, winding as regularly as possible. When finished, the loop joining the coils can be easily bent out of the way. Saturate the coils with thin shellac varnish. When dry, the centre piece of wood is split in two, and the pieces pulled out. There is then left a space between the coils to lower the needles into. The bobbin is then fastened centrally to the base board by two brass lugs. Two holes in the board are drilled. The ends of the wire are passed through and led underneath to the terminals.

Take a 3½in. card, graduated in degrees, and cut a slot 1½in. long, 3/16in. wide. This slot should be along the line joining the two 0° divisions on the card. It is then fastened centrally on the coils by two small brass screws. The support for the needles is made of brass rod, 3/16in. thick, 8½in. long. It has a screw cut on the bottom end, and is screwed into a hole in the base board. This hole is about ¼in. from the groove for the shade. A piece of the card outside one of the 0° divisions has to be cut away to allow the rod to pass up. About 6½in. from the bottom end the rod is bent at right angles, and when in position overhangs the slot in the card. At a point vertically above the centre of the card and coils a hole is drilled and tapped, through which a brass screw works vertically. Its use is described below.

The needles are made thus: A piece of thin brass sheet about 1in. long and ⅛in. or less wide, has cemented to it by varnish two parallel pieces of magnetised watch spring, 1¼in. long, and from ⅜in. to ⅝in. apart. The north pole of one needle must be over the south pole of the other. The brass strip is at right angles to the needles, and one end projects beyond the top needle. This end has a hole in it to which the fibre is attached. This fibre, which is drawn from a silk ribbon, is fastened to a hole in the bottom end of the screw overhead.

When using the instrument, turn the screw till the needles are at the right height, and then adjust the levelling screws till the needles swing freely in the centre of the coils. I omitted to mention that a pointer of thin brass wire is stuck on the top needle. One of these instruments may be seen at work, during the first four evenings of the week, at the address given below.

96, Crawford-street, W. **G. Bowron.**

## A NOVEL CLOCK.

[24327.]—Referring to "Garrison Gunner's" letter 24297, p. 282, the following paragraph from a paper on Horology, in "Chambers's Information for the People," published in 1857, will show that "G. G.'s" idea was anticipated at least 28 years ago: "In another, the dial formed the brim of a plate, filled with water, in which swam a tortoise, turning marvellously with the hour, and ever even pointing towards it by magnetic attraction, as everyone would now readily conceive, and this favourite idea was varied by many other simple contrivances."

Birmingham. **C. F. A. Underwood.**

## EVOLUTION.

[24328.]—A "Convert from the Theory of Evolution" makes a statement at the head of his letter which is rather too positive, and which makes his following words, "some who know so well," look rather ridiculous (and this applies still more to a subsequent statement in his letter). I can't see *why* life must have been a process of evolution in order that evolution should exist, neither does the "Convert" tell us. Why may not life be the *cause* of evolution? The following words, "habit, custom, and necessity," of his letter seem to me to presuppose life. The second question he asks might be asked in hundreds of cases of everyday events, which I think even he would admit are not special creations; but which he, nevertheless, cannot explain.

I should like the "Convert" to distinguish in his next between "evolution of life itself," "spontaneous generation," and "special creation." One of these terms has no meaning at all for me, and the other two seem to be synonymous. We do not know what life is, and until we do I don't see that we can tell whether it was originally "evolved" or "spontaneously generated" or "specially created," or has existed as long as matter itself.

The "Convert" also asks, "What need even for sexual arrangements?" This may be asked with regard to "special creation"; sexual arrangements seem to me to be more unnecessary to special creation than to evolution; for if "evolution of life from elements is certainly more simple than reproduction by complex processes," is not "special creation" simpler than either? Are not "evolution" and "reproduction" more compatible than "special creation" and "reproduction"? And in saying that "evolution of life from elements is certainly more simple than the reproduction" which does go on, the "Convert" seems as likely as anyone to answer his first question (since he "knows so well").

The "Convert" says, "The truth is, the theory of evolution is thoroughly unscientific," which is something like saying that Darwin was thoroughly unscientific. I wonder the "Convert" was *ever* influenced by "the speciousness of the theory." Neither theory is *known* to be true, therefore the one is as much "a scheme of suppositions" as the other; and if the method is a "novel" one that is nothing *against* it. As to "amputation of argument," I think this, like many other of the "Convert's" statements, applies to both sides, and "random assertions of some who should know better" have been made on both sides. Whether rudimentary organs are perfecting or the reverse, it is evolution, and, therefore, "real evidence." Lastly, the unity spoken of seems to me to extend the theory of evolution if anything, and not in any way to disprove it. I sincerely hope the above contains "some common sense," and will do a little towards reconverting the "Convert," and shall look forward to seeing another letter from him soon. **Crumby.**

## EVOLUTION.

[24329.]—"F. W. H." in letter (24282, p. 279) begs the entire question, when he asks "how can any man know that a 'quality' is not previously existent, even in a latent state"?

I go back to what is called the first simple organic form, and I say that that form contained in a latent state all the multiplex characteristics, structural, as well as mental, which have since then been in existence; or else, it did not.

On the assumption that it did, evolution is a possible explanation of nature as we find it; but then, the march has been retrograde, not progressive. From an apparently simple physical form, yet nevertheless, an inconceivably complex one, we have, during the life-history of this planet, been marching towards forms structurally more complex, none of which, however, contain in so concentrated a degree the essential characteristics, physical and mental, which the original form possessed.

I repeat, that it is inconceivable that this first, so called simple organic form, could have held latent within it, all the characteristics, physical as well as mental, which have existed or are now in existence between simple protoplasm and adult man.

"F. W. H." invites me to the consideration of embryology—a study which I have not altogether neglected, where, "we have an infinitely small speck of protoplasmic matter, evolving within the short space of 20 years, a perfect adult man."

I confess it is sufficiently embarrasing to conceive how such a small speck (*not infinitely small*) of protoplasmic matter can contain latent, the diversified characteristics of one adult man; but how such a small speck of protoplasmic matter can contain latent the diversified characteristics, physical as well as mental, of all men, *and of every organic form which exists or has appeared*, is, to me, unthinkable.

On the other hand, this first organic form or protoplasm *may not have contained latent* all these varied characteristics.

It may have contained some, or a few, which, for convenience, we may designate—those of its own species.

Now, what I was anxious to point out in my letter (24256, page 257) is, that "evolution" claims as a necessity (the agency of which, or the explanation of which, it cannot elucidate further than to say that it is something outside of natural selection) that new and previously non-existing characteristics do, from time to time appear; and these, I hold, can only be referred to "creation." If "F. W. H.," or any other, can give me a scientific explanation of how these new and previously non-existent forms do appear, I will be only too glad to accept it.

I need scarcely point out that in these discussions, and, as a matter of convenience, it is customary to use figurative language. When we say "creation" does so-and-so, we obviously personify it, and refer to a creative power; and when we say "evolution" does so-and-so, we personify it, and refer to the protoplasmic matter itself, with its latent qualities, or else—let others correct me—to the struggle for existence. For the sake of sense, this fact should not be lost sight of.

Further, it is, in my opinion, desirable that in discussing such subjects, preconceived theory or belief should be, as much as possible, laid aside, if reason is to have fair play.

If "F. W. H." had been so guided, he would not have imputed to me, in the closing paragraphs of his letter, sentiments which I have not either implied or expressed.

I do not hesitate to say that, with the evidence before me, I believe that "creation is constantly at work, producing fresh 'special' previously non-existing qualities," not in man only, but in all organic forms, and I challenge "F. W. H." to show how otherwise these "special, previously non-existent qualities" which "evolution" requires but cannot explain, can have been brought into existence. He ought to have observed that my remarks were directed solely to organisms, when I spoke of the appearance of new and previously non-existent characters, and that I did not even suggest the appearance of totally new matter which previously had no existence, or "something out of nothing."

The artlessness of "Crumby" is truly refreshing, and the example he affords of working up to a preconceived theory is typical of many, on either side of the question, when he says, "I think if 'P.' studies the chain of existing and fossil creatures known, he will find that there are no very great gaps; some gaps may be greater than others, but I don't think that is any reason for rejecting the theory for them, even if they are inexplicable from an anatomical point of view."

Let "Crumby" and those whom he represents go to the root of the matter, and explain to "Ours" how new and previously non-existent organic forms or varieties can have come into existence without "creation."

I ask this the more readily because "Crumby" disagrees with me in my statement, that previous discussions on this subject seem to have brought the disputants back to where they respectively started from. **H. B. F.**

---

[24330.]—"PRE-ADAMITE" seems to be in a fog, as the rest of the world was when he came into ? "being," or when the final step (? is it "final") in his evolution was taken. He must give it up as a hopeless conundrum. If he gets away from his wicket too soon, he is stumped. If he remains humbly waiting for the next ball, he is bowled out. Evolution seems to have required "from eternity" to arrive thus far, and to need "to eternity" to complete itself. Will it evolve itself from nothingness to nothingness, and then, winding itself up, begin again? It is too deep for **Pre-Adamite.**

---

[24331.]—HAECKEL says ("Pedigree of Man," p. 33): "The first of these two inquiries, that as to the first appearance of living beings, can only be decided empirically by proof of the so-called archebiosis, or equivocal generation, or the spontaneous production of organisms of the simplest conceivable kind. Such are the Monera, Protogenes, Protamœba, Protomyxa, Vampyrella, exceedingly simple microscopic masses of protoplasm without structure or organisation, which take in nutriment, and reproduce themselves by division. Such a Moneron, discovered by Huxley, the Bathybius Haeckelii, appears as a continuous thick protoplasmic covering at the bottom of the ocean, in depths from 3,000 to 30,000ft.

It is true that the first appearance of such Monera has not, up to the present moment, been actually observed; but there is nothing intrinsically improbable in such an evolution, &c.

Further on (p. 34) Haeckel puts the case in a nutshell—viz., it is substitution: "In the place of an arbitrary act of creation, we have a necessary law of evolution." **F. W. H.**

## EVOLUTION—TIME TABLES.

[24332.]—"F. W. H." (letter 24282) is right in holding the idea that something can be made out of nothing to be mere nonsense; but he should remember that the Christian definition of creation is that "things which are seen were not made of things which do appear" (Hebrews xi. 3), which implies that they were made out of things that previously were invisible; and surely in these days of the liquefication of gases such a statement cannot be regarded as "unscientific." Whence those invisible things came is another question, and has nothing to do with Darwinism.

Printing p.m. hours in thicker figures than the a.m., or *vice versâ*, would be a far better plan than going on to 13, &c. The hour meant would be seen at a glance by the most hurried traveller. **K.**

## THE NEW TIME.

[24333.]—WILL you allow me space for a short comparison of the merits of the present and proposed methods of marking the time? I have put down, as far as I can see them, the reasons for and against the new time, and leave it to your readers to draw their own conclusions.

In favour of the new system. 1st. That the new time is more scientific and accurate than that at present in use. 2nd. That it would form a basis for a universal time. 3rd. That railway time tables would be more simple and less likely to be misunderstood if the 24-hour notation were used. 4th. That a few people—perhaps one in ten thousand—are in favour of the change.

For the retention of the present method of marking time. 1st. That the present system is more convenient for the reasons below.

In naming any hour, the use of one syllable instead of two or three which would be required under the new system, is an advantage, still more so in writing. That there is no form of clock so simple and easy to read as the 12-hour one; watches and clocks showing 24 hours either have the hours crowded, or require extra mechanism to show the hour, and in either case the figures are less plain and cannot be seen at the same distance as an ordinary dial.

That none of the advocates of the new system agree as to the best plan of striking the hour; the plan advised by "F.R.A.S." would lead to much expense with no adequate advantage. To alter the church dials all over the country would be a great and unnecessary expense, and if done only in part would be a great cause of confusion and discomfort. The same may be said of the clocks in everyone's house.

2. That even if a universal time is desirable, of which I have some doubt, the present system being in almost universal use, is at least as well suited to the change as the 24-hour system.

3. That with ordinary care there is no difficulty in finding the times of trains starting by the ordinary railway time-tables. When mistakes do occur they are mostly caused by careless printing of the tables; under the new system a greatly increased number of figures would be required, and mistakes would be more likely to occur.

4. That no one felt the least difficulty with regard to the 12-hour system until the new time was proposed, and that the bulk of the people are not at all inclined for the proposed change. **Lavant.**

## THE USE OF COMMUNICATION CORDS ON RAILWAYS. — TO "CARLISLE PASSENGER."

[24334.] — CONSIDERABLE doubt has always existed as to what constitutes a "reasonable and sufficient cause" for a passenger using the communication cord on trains. Several passengers have at various times been fined, and consequently instances do occasionally occur in which trains are not stopped when they should be. My own opinion certainly is that your correspondent would have had "reasonable cause" to stop the train. Having been requested by several passengers to communicate with the company upon the subject, I wrote to the general manager, and now inclose his satisfactory reply.

**Clement E. Stretton.**

Saxe Coburg-street, Leicester, 26th May.

COPY.

"Midland Railway, General Manager's
Office, Derby, May 25th, 1885.

"Dear sir,—In reply to your letter of the 22nd, I think, under the circumstances, a passenger would have been justified in using the cord communication.—I am, yours faithfully,

JOHN NOBLE.

"Clement E. Stretton, Esq., Leicester."

## JERKS IN RAILWAY TRAINS.

[24335.]—IN reply to your correspondent, "One of the Passengers," I may say that the jerk is caused in the first instance by the running of the unbraked fish vans at the end of the train into the front portion, which is retarded owing to the action of the brakes. When the train has stopped, the compressed buffer springs react, and the fish vans are forced backwards, thus causing a sudden wrench on the couplings. There are still many of the Midland trains running with the "leak-off" form of the vacuum brake. This makes the effect of the above-mentioned jerk more serious, for as soon as the brake leaks off there is nothing to hold the train, and it is suddenly jerked backwards, sometimes for a distance of two or three yards.

It is, unfortunately, too common an occurrence for railway companies to run vans, horse-boxes, &c., unfitted with a brake at the end of a train which is fitted. I have known numbers of couplings to have been broken from this cause. It is also a very common practice to fit such vehicles as the above with connecting pipes only, the brake itself not being applied to the wheels. These vehicles are then run in all portions of passenger trains next to the engine, in the centre of the train, or at the back end. The effect of this dangerous practice is easily seen. In my opinion, *all* vehicles intended to form part of a passenger train should be fitted with a reliable continuous brake, and this brake should be applied *to the wheels* of all such vehicles, whatever their description.

The carriage-trucks, horse-boxes, fish-vans, &c., on the North-Eastern Railway, are nearly all, if not all, so fitted, and great praise is due to the company for this reason. Unfortunately, this railway is one of the exceptions.

Your correspondent has evidently read the discussion on "Jerks in Trains," which took place in your columns some years ago. I may mention that the jerk there mentioned is not of the same character as the above, and by no means so severe in its effects. In order to shelter themselves from blame, some companies give out that the passenger leaves the train "when in motion." Certainly the train is "in motion"; but this motion is entirely due to their own negligence, and occurs at a time when the passenger has a right to leave the train. The sooner some companies understand that they cannot trifle with the safety of their passengers the better. Heavy damages in a case such as the one mentioned would go a long way towards producing some effect. The Midland Railway Company are among the greatest offenders in respect to cases like the above. **Meteor.**

## MUSICAL SCALE.

[24336.]—DURING my experience I have frequently sung the chromatic passage referred to by Mr. Hardie in his last letter on the musical scale (24265) for the purpose of comparing the three semitones contained in it, and am satisfied that the middle semitone is less than the other two, which are equal.

Each of the intervals (G—F) and (F—E) is a major semitone, and is expressed by $\frac{15}{16}$. The sum of these intervals is $\frac{125}{256}$. If this compound interval be taken from $\left(\frac{5}{6}\right)$, the minor third between E and G, the remainder or middle interval will be $\frac{128}{156}$ which is less than $\frac{15}{16}$ by $\frac{2025}{2048}$. **W. U.**

## LEGAL REPLIES.

[24337.]—EXECUTORS — SECURITIES (56345). — These securities should certainly be placed in a bank, I should say. There is no regular rule in such matters, which are generally arranged amicably. There could be no legal effect given to the wishes of the majority.

REFERENCES—POSSESSION OF DOCUMENTS (56355). —These references were apparently written as private letters to the querist's late employer, in answer to applications from him. They are, therefore, the private property of the employer as much as any other letter addressed to him would be, and so cannot be claimed by the servant on leaving. I should hardly think copies would be of any use, and the only way is for the new employer to write to the references over again.

MORTGAGES—SALE—TITLE (56381).—I cannot see what the sons mentioned have to do with this property, as far as the facts are stated. Mother and daughter seem to have joined in the mortgage, and I do not think the mortgagee would have advanced his money without seeing that they had a good title. Even if there ever was any claim in the sons, as the sale seems to have been over 12 years ago, it is barred by the Statute of Limitations.

EMPLOYERS' LIABILITY ACT (56457).—In the case put by this querist, I do not think that either the employer or the millowner would be liable. Employers are only liable in the special cases set out in the Act of 1880, none of which would cover this question, as the foreman ordering the dangerous work to be done was not in the master's employment. If workmen will put themselves in positions of danger, they must take the consequences. The rule of law, as to the risks of the service, is not altered by the statute. As I understand this case, the workman set to work upon machinery in motion, well knowing the danger. He should have refused. If, however, the machinery had been stopped, and then set going while the man was at work, he could have recovered damages from the millowner. It is quite a mistake to imagine that every case of injury gives a right of action against somebody. The legal maxim is certainly that for "every wrong there is a remedy." But that means a wrong in the legal sense—that is, an actionable wrong, and it can generally only be supported by proof of negligence.

NOTICE TO QUIT—EJECTMENT (56467).—The rent of the shop is not stated; but I presume it is under £50 a year. If so, the querist's best and quickest course is to bring an action of ejectment against his tenant in the county court in the district of which the premises are situated, and upon proof of the tenancy and the notice to quit, he should receive judgment to obtain possession.

PROMISSORY NOTE—SOCIETY—FRAUD (56471).—This querist does not appear to have read the note itself before signing it. If it is drawn for £4 10s., he has made himself liable for the whole of it, unless he can show that his signature was fraudulently obtained, and that he really only meant and was intended to be surety to the extent of £2. To prove fraud he can give evidence himself, and call the borrower as a witness to support his contention; but I am quite unable to say what decision the judge will come to after hearing both sides.

COMPANY—DEBT—WINDING UP (56522).—If the querist has a valid claim against the company, all he can do is to send it in to the liquidator in the winding up. His being paid will depend upon the assets of the company, and he may only get a composition.

JUSTICE'S MANUAL (56529).—The best, simplest, and most readable book of this kind is undoubtedly "The Justice's Note-Book," by Mr. Knox Wigram, a lawyer and justice of the peace. The fourth edition is now published by Stevens and Sons, Chancery-lane, at 12s. 6d., cloth. I have used it myself, and never found it to fail me when looking up a point of magistrates' law. It is as wittily written as it is complete and accurate. The other works are "Oke's Magisterial Synopsis," a large expensive book in two volumes; and "Greenwood and Martin's Police Guide," also costly. The "Justice's Note-Book" is really a concise and alphabetically-arranged epitome of the criminal law that anyone could read and understand.

RATES AND TAXES—ASSESSMENT (56532).—The Queen's taxes will follow the assessment for the poor-rates, and, therefore, as the querist has got his rates reduced from £40 to £32, his taxes should come down from £50 to £40. Upon a proper representation to the collector or surveyor for the Queen's taxes, I think this view will be adopted.

LEGAL NAME (56545).—I see this query has already been answered by two correspondents, who differ. I do not agree with the Vicar, who is evidently writing what is ecclesiastical law. As far as there is such a thing as a "legal name" at all, I should say it was the name under which the child was registered, which in civil law quite supersedes the baptismal name. But a man may take any name he likes, only he runs some risk of confusion if property should be in question. For the rest I agree with "B. Sc., Plymouth."

**Fred. Wetherfield**, Solicitor.
2, Gresham-buildings, Guildhall, E.C.

## HOW SHOULD THE STARS BE MAPPED?

[24338.]—OF how flat a curvature can glass spherical segments be blown? The question arises now that the stars are to map themselves, because plane fields, wider than a few degrees, cannot take images distinct at both their centre and margin; so that the number of them to map the whole heavens will be many. Whether plane or not, they should all be equal circles; and whatever their number, 12 each should overlap five neighbours, and the remainder each overlap six. A whole set must be a number of one of these two forms; either $10 a^2 + 2$, or $30 a^2 + 2$: the former when each pentagon presents a side towards each of its nearest fellows, and the latter when it turns a corner towards each. (The centres of two neighbour pentagons are always distant by the arc whose tangent is two.) Thus the 16 simplest sets are—

| | | | |
|---|---|---|---|
| 12 | 122 | 362 | 752 |
| 32 | 162 | 482 | 812 |
| 42 | 252 | 492 | 1,002 |
| 92 | 272 | 642 | 1,082 |

But if the 32 were made with their 20 hexagons regular, the side common to these and the pentagon is 23° 16′, making the circumscribing radii for the two very unequal, 20° 5′ and 23° 49′. These should be equalised, each 22° 41′, by making the hexagon's sides alternately differ. In other cases the hexagons, or some of them, will not be quite inscribable in a circle; but more nearly so the more numerous they are. In the next case the 30 are all alike, but require one diagonal twice 20° 53′, while the halves of the other two can be equalised to the pentagon's circumscribing radius, about 20°. The next set, 92, can all be circumscribed very nearly by a radius of 13°, but even this is too wide for plane maps.

Probably the 362, admitting a common circumscribing radius of 6° 31′, will be the fewest planes to take the whole sky. Will not glass rather be taken then on the mouth of a wide funnel, into which a measured quantity of air can be sent and not allowed to contract?

The age of planetule hunting of course will end, as all those bodies, known and unknown, will declare themselves in lines instead of points.

Photographs taken on a concave surface could, by the same lens, or one of equal focus, be copied on a plane, either of nearly the identical scale or larger; but I never heard of this being done: nor have I seen any picture of great angular width and the distinctness this would give.

2nd June. **E. L. G.**

# REPLIES TO QUERIES.

⁂ *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[54698.]—"**Round**" or "**Around.**"—For the information of "Os," I will give the following quotations from the best of English authors to show that "around" is not an Americanism, nor a survival in America of an obsolete English term, but that it is English "pure and undefiled." As "Os" objects to poetic quotations, I have taken them from articles on astronomy. To be brief, I have taken but one quotation from each auther, whilst I could give a great many more. I have no work on astronomy that has not *around* in it. Newton's "Principia," by Motte, Book III., proposition xiii., thorem xiii.: "They less disturb the motions of the planets *around* the sun." Written 1729. Nicholson's "Encyclopedia of Arts and Sciences": "The circle *around* where the earth and heavens seem to meet" (1805). "Edinburgh Encyclopedia," by Brewster: "There is no nebulous appearance *around* the planet Juno" (1812). "Outlines of Astronomy," by Herschel, 10th ed. page 42: "He will then perceive above and *around* him a vast concave hemispherical vault." "Christian Philosophy," by Dick, page 83: "She is the constant attendant of the earth, and revolves *around* it in 27 days." "The Moon," by Nasmyth and Carpenter," page 53: "The moon, while revolving round the earth, is, with the earth, revolving *around* the sun." "The Moon," by Proctor, page 17: "The equatorial telescope turning *around* its polar axis." "Arnott's Physics," Art. 1,027: "An unobscured view of the horizon *around.*" "Climate and Time," by Croll, page 1: "Agencies at work *around* us." This needs no comment; but I will say to "Os," "F.R.A.S.," and others, read English works on astronomy, and mind what you read, and you will not need an American to enlighten you further with regard to the English word *around*, nor will you any more make America a scapegoat for your ignorance concerning it. "Abed" was used by the poet Spenser over 200 years ago, so it is no exotic in your soil; and if it has become fossilised, you can dig it up: you need not import it. Would "F.R.A.S." wish to ignore the 100,000 or more words introduced into English since the days of Shakespeare, and fall back upon the 8,000 words used by him? I think not.—JAMES BIRD, Atlanta, Louisiana, U.S.A., May 11th.

[54825.]—**Salt, &c.**—"F. W. H." fails to understand why I should begin with a civilised man. The reason is this: it is a law of Nature uniform in its operation, and admits of no exception, that you cannot get out of anything what is not in it; consequently, if these so-called primitive men were our ancestors, they must have had in them all the powers and capabilities of the human race. Then if the lower (or so-called lower) contained all that is in the higher, in what sense or how could they be lower? If the fitness of things, the history of the past, as well as the every-day experience of the present time are also taken into account, then beginning with man in the full possession of his powers is a necessity of the case. Besides, this trying to begin with low-type man and so on up to higher is only a quasi-arrangement to suit a theory, and this theory of the self-advancement of a species, whether of men or animals, is in flat contradiction to the law and facts of Nature, as well as the experience of every-day life, and stands in the position of being a conclusion in search of its premise. "F. W. H." also, in letter 24282, seems to have allowed his great love of evolution to mix his "embryology." A human embryo is not "an infinitely small speck of protoplasmic matter," and it does not "evolve." It is a human being, having in it all and everything that it will ever possess, and it grows in strict harmony with the law of its being; and the same with the acorn, which contains the future tree. As to the difficulty of a special creation, the difficulty is not in the doctrine, but with those who will not have it, although many of them are prepared to believe and accept the doctrine that man with all his powers was evolved from a "squid" (see Darwin's "Descent of Man").—DENS.

[This must end the long series of rejoinders. "Salt is good," &c.—our correspondents will remember the rest of the text!—ED.]

[55819.]—**Micro. Adjustment.** — Thanks to "Menesicus" and "Glatton" for their replies; but am sorry to say they are not applicable to my stand —a Jackson-Lister. The one I want is with the lever in the form of a ring bearing on both sides of objective tube, and worked by milled head on side of body.—SEMPERVIVO.

[55826.]—**Gas Oil.**—To "INVICTA."—In reply to above inquiry you promised to forward pamphlet if I advertised my address, which was accordingly done in issue of March 6th last. As yet no pamphlet has arrived. Please explain and oblige.—JAY JAY SEE.

[56204.]—**Calorimetry (U.Q.)**—A summary of the researches of Favre and Silberman on the heat of combustion could not be given in the space of a reply: it would need an article. If there is any special point upon which "Equivolt" desires information, I shall be glad to help him—if able.—WM. JOHN GREY, Analytical Chemist, Newcastle-on-Tyne.

[56411.]—**Power of Electro-motor.**—What does this querist mean? How is it possible to tell what power the motor will exert with such data as he gives?—S. T.

[56412.]—**Fire for Brazing.**—Any fair-sized blacksmith's fire will do.—ANVIL.

[56419.]—**Veterinary.**—There seems some mistake in this query: quinquinia is not quinine; but the quinine should be dissolved in the iron solution before adding the strychnine tincture.—M. P. S.

[56420.]—**Waste Oil.**—Filter through felt, then through animal charcoal, and you will soon discover whether the oil is of use or not. It would be scarcely worth while to steam it, and add acid, as in the usual bleaching process.—ESSAR.

[56423.]—**Electro-Brassing.**—This querist should look up his back numbers for methods of electro-brassing, notably No. 825, on p. 441 of which he will find an article describing the process. Details of various processes in Gore's "Electro-Metallurgy"; and a special article in Vol. XXXVI. ENGLISH MECHANIC, p. 290.—CYRAX.

[56424.]—**Softening Sheepskin Rug.**—Lay a damp cloth on the skin side until quite soft, and then work the skin well and frequently by crumpling it, as it were, between the hands, or stretching it over the back of a chair. Repeat until dry, and you will probably find it soft. To wet leather, and leave it to dry, is to find it hard.—NUN. DOR.

[56426.]—**Old Locomotives.**—Apparently the list refers to the first engines on the Liverpool and Manchester line—at any rate, the first eight names are well known as the engines that took part in the formal opening.—MOTION-BAR.

[56430.]—**Leaky Air Cushions.**—Paint over the leaks with solution of rubber in bisulphide of carbon, and, if necessary, stick on a patch of linen or calico with the same solution, and coat the outside well.—NUN. DOR.

[56431.]—**Pickle for German Silver.**—"Max Tour" should wash the pieces thoroughly after pickling, and dry off in hot sawdust. Keep in dry bran or chalk.—BRUM.

[56432.]—**New Midland Engines.**—Have these engines been taken off the Scotch expresses? I fancy I saw one of them running through Kentish-town the other day with an express train.—ARGUS.

[56435.]—**Cutting Clock Wheels.**—Simply a milling tool; but an index plate is required.—GARNAULT.

[56436.]—**Chemical.**—It is not quite clear what it is this querist wishes to learn. Glauber's salt is "sodium hydrogen sulphate."—M. C.

[56437.]—**Chemical.**—"X. Y. Z." can be referred to the *Transactions* of the Institute of Chemistry and Payen's "Industrial Chemistry."—VIDEO.

[56438.]—**Fastening Fish-forks in Handles.**—Use a powder of rosin and brick dust, half and half.—ESSAR.

[56449.]—**Filling Sand Holes in Brass Rollers.**—The best way is run them in with brass solder or spelter; but they may be filled with ordinary hard solder.—RETOUCHER.

[56452.]—**Tennis Lawn.**—The lawn on a clayey soil will take a long time. Proper turfs should have been laid on drained ground.—T. H. L.

[56453.]—**Paper for Copying Process.**—Tissue is too thin and delicate. Use one of the strong thin papers commonly called foreign post, and coat with wax, paraffin, or Canada balsam.—N. E. CHILD.

[56455.]—**Hancock's Inspirator.**—This is a sort of double injector, in which the water is drawn into one chamber by a small jet of steam, and is forced into the boiler by an ordinary injector jet. I believe it has been illustrated in back volumes; but have no time at present to look.—NUN. DOR.

[56547.]—**Geometrical.**—It may be interesting to "M.I.C.E." and others to consider the general theorem of which this is a particular case. If *a . b . c . d* be the four lines forming four triangles, *a b c, a d c, a b d, d b c*, we get—(1) By projection. Projecting all the circles into conics passing through two fixed points, the theorem, If four conics be drawn circumscribing the four triangles formed by four straight lines, and also passing through two fixed points, they will also all pass through a third fixed point. (2) By reciprocation, the four lines become four points, *a . b . c . d.* forming four triangles, *a b c, a b d, a d c, b d c*. The circles become conics touching the sides of the triangles and two fixed lines. Hence we get: If four conics be described, each touching the three sides of one of the triangles, and also touching two fixed straight lines, they will all touch a third fixed straight line. In each case the conics are all determinate, for there are fixed conditions to be satisfied by each conic.—T. H. L.

[56550.]—**Sawing.**—In the first place, your saw is just 1in. too narrow at the bottom according to the top, through bad sharping, and perhaps filed hollow as well, so that would make it too light altogether. It is only a useful saw for ripping or cutting small logs. I should advise you to get two new saws, and order them yourself, from Messrs. Atkin and Son, Birmingham, as I think they make about the best pit saws that can be got, and you will get the two for about £1 15s. or £2. The reason I recommend two is that you will not be able to cut different sorts of stuff with one saw, not being used to the job, as it will require a great deal of altering in the sharping to cut hard and soft woods. The saws I should recommend are the same as I get myself—that is, 6ft. 6in. long, ⅝in. space, 12in. heel, 14 gauge on face, and 15 gauge on back. As to sharping, there is no proper degrees (or angles) for holding the file, because you might sharpen for a soft nature of timber, and when you come to cut it, it would, perhaps, be harder than you expected, and then it would want altering for harder, or otherwise it may be the opposite way. The greatest art after you have a good idea of sharping, is to know the nature of timber, and that you will learn as you go on; so if you sharpen to cut an ash tree and it is a hard one, that sharping will not do to cut the elm with, as ash is very hard when it is dry; but if it is a very soft ash, it might cut a very hard elm with a little attention; but when you sharpen to cut your ash (keep the face of your saw as straight as a straightedge by running the flat side of your file lightly down the face of your saw, so that one tooth will not be higher than another, and mind that the file is properly level, so that one side will not be higher than the other), top your saw after ranging it down with not too much bevel till you have just cleared the file mark off; then gullet your saw, and mind that there is enough hook put on, or else it will be sure to hollow, and so, if there is too much. You must know the nature of your stuff, and always file enough hook on, so that if there is too much on, it can easily be hooked back a little with the file; and when you start working, if there is too much on, notice what part of the saw picks most, and knock it back a little till it goes down sweet, and if it goes down too easy, there is not enough on. In elm put a little more bevel and more hook, and set so that the saw just clears itself, and if it is inclined to hollow, put a little more hook on the side that is weakest, or a little more set on that side; and so on till you get on better. Always alter in time, as it will go further. There are different kinds of turning or felley saws, and different sizes. If you do not like advertising your address, post a private one to some post-office, and I will give you more advice.—I. M.

[56551.]—**Wheelwrighting.**—"Alabama" does not say what kind of wheels he wants to get old spokes out of naves, or if he wants to use either again. If he does not want to use naves again drive the hoops off, then split the nave and spokes will fall out. If he does not want to use the spokes again, lay the wheel face downwards, cut a notch in back of spoke 4in. or 5in. from tongue, lay a block under spoke, then a few sharp blows with adze will draw spoke out, if he wants to use spokes again lay wheel in position as directed above and use ring and wedge instead of cutting notch in spoke; use adze instead of sledge.—H. J. HUMPHREY.

[56569.]—**Boiler Query.**—I do not think it would be wise to increase the pressure of your boiler to 75lb., being all single-riveted, as applying gussets to ends would not add strength to the shell, which can only be taken as given by me—viz., 257lb. bursting pressure. Under the Board of Trade 257 must be divided by 8 to get working pressure, which would only give 32lb. Lloyds would give 43, which is ⅙, but the insurance companies would divide by 4, or even less in competition, but would not give more than 70lb. working pressure, the weakness being in the single riveting, which cannot be strengthened. The strength of the furnace may be taken as follows: Thickness multiplied by thickness multiplied by 806,300 and divided by length, multiplied by diameter = collapsing pressure, or $\frac{806,300 \times T^{2.19}}{L D}$ = 285lb., which, divided by 4, gives 71lb. safe working pressure, the length of tube being taken from first cone tube to front end, that being the longest portion unsupported. All boilers for 70lb. and over should have a gusset at back end below and two at front. Longitudinal rods are not absolutely necessary when well stayed with gussets for under 75lb.—BOSWELL.

[56573.]—**Chronic Rheumatism.**—To "B Sc., Plymouth."—In reply to "A Many Years' Subscriber" (1), it should be a coil worked by a battery, (2) Leclanché cells. (3) Niemeyer strongly recommended the continuous current in cases like yours; but the induced current discovered by Faraday and applied by Duchenne has, to my thinking, met with greater success. (4) There is nothing to hinder your electrisation in bed, although I think you will not feel any cold sensation in the exposed skin when the elastic brush is passed over it. (5) Application: Sponge the part affected with sea water, or a solution of Tidman's sea salt, and keep all the part moist during the application of the current. The pads or sponges (having handles attached and connected with wires to the P. and N. poles of the battery) must also be kept moist when in use, in order to lessen the resistance. Begin with applying both pads to the part of the skin complained of, keeping the one stationary and moving the other gently over the surface, say, for five minutes, then substitute the wire brush for one of the pads, and pass it also gently over the surface for five minutes. This will be enough per day to begin with. Increase gradually up to a 30-minute séance. Further, I would recommend Hirschman's (of Berlin) apparatus as the most suitable. The only bother is that one may have to wait (as I did) six weeks from the time of order through a surgical instrument maker until receipt. The price is from £3.—B.Sc., Plymouth.

[56578.]—**Electric Bells.**—Although it may be possible to have telephones working well when joined up in parallel circuit, and using "earth return" (similar to Fig. 2 on page 286), it is hardly possible to get the same result from a number of electric bells separated from each other by some miles of wire when joined up in the same way. The reason of this is:—A good telephone will generally respond to a current of $\frac{1}{10,000}$ of an ampère, whereas a carefully-made bell relay would require quite four hundred times that amount, or about 40 milli-ampères. Now, when a circuit is joined up similar to the sketch just mentioned, and with the stations some miles apart, the greater part of a current sent from No. 1 station passes to earth at station No. 2. Similarly, the lion's share of the remainder takes the same course at station No. 3, and so on, so that when the last station is reached, the received current is small indeed. This would probably be ample for telephonic purposes; but I should say useless for call bells or bell relays, unless they are very delicately made. I trust I have made it clear to "Electra" that it is almost impossible to get a bell circuit to work satisfactorily under the conditions he names. I am still of opinion that the "closed circuit system" is admirably adapted for such a bell circuit, but joined in series, of course, as only one battery of, say, 10 Fuller cells would be needed for the whole circuit. This is, of course, supposing that the wire is not already connected up to telephones, as I fancy his last few lines on p. 286 seem to imply. If such is the case, and "E." wants to add call bells, it is another consideration altogether, depending to a great extent on the pattern, &c., of most telephones.—H. S. BEACH.

[56580.]—**Tricycle Pedals.**—To "U. C. S.W."—Are you not "sorry you spoke," and thus spoiled the outflow of more experts on the question? This week we have yet another friend, "Lithium," falling into the same error; whilst had you not drawn attention to the fallacy, that has much amused me as I read the replies, we should have had several others doubtless making the same error. This little matter should show amateurs that very many persons write without thinking. That the information is gratuitous is acknowledged. But I would like it to be a boast of this journal, that erroneous instructions and advice are conspicuous by their absence. "U. C. S. W.," I fancy, is a new contributor—at least his initials are new to me. But he has done good service by dropping on such a simple error as the one in question. Amongst certain classes the contributed matter is ridiculed enough, without giving additional chances of doing so by being aided and abetted by impossible mechanical errors. Personally, I would like to see the reply pages filled with such answers that it would be simply impossible, consistent with truth, to cavil at the statements to be found therein.—INVICTA.

[56580.]—**Tricycle Pedals.**—I understood this query to refer to a central-geared tricycle: hence my reply last week. "C. D. R." appears to have fallen into the same error. However, our common mistake is not altogether a matter of regret, seeing that it has called forth the letter of a Cardiff correspondent, a production which strongly reminds one of the accounts travellers give of an Indian scalp-dance. Our Welsh friend seizes on "C. D. R.'s" well-intentioned, though, perhaps, mistaken suggestion, fiercely whirls it aloft (so to speak), and calls sarcastically for a diagram. Perhaps he will not be too severe on me if I venture to point out that it is not only possible to put a washer, or what will serve all the purposes of a washer, on the pedal of a crank tricycle, but a very easy thing to do, too. All that is required is a bit of steel rod of a square section—say, ½—which should be bent round while hot, and the ends brought neatly together; the pedals, of course, being first removed. Any blacksmith can do the job in a couple of minutes. I have seen washers of this description which work well enough, and the querist (Calvert) had evidently some such idea when he mentioned "spring washers." Of course I don't mean to say anything against "Invicta's" method, which is probably the best; but then amateurs usually find brazing a rather awkward job.—LITHIUM.

[56604.]—**Differential Equation.**—The equation $\frac{d^2y}{dd^2} - a\frac{dy}{d\zeta} = 0$, may occur in some geometrical problem, but it occurs in the mathematical theory of heat, where $y$ might express the temperature in a bar at a distance $x$ from the origin at a time $z$, no radiation being supposed into space from the sides or extremities of the bar. Other similar problems are likewise represented by the equation. The general solution of the equation is given in Poisson's and Fourier's treatises on the mathematical theory of heat, and also I believe in Boole's differential equations. "M.I.C.E." has given a solution of the equation, but not "the solution." A very general solution is—

$$\sqrt{\pi}\,.\,y = \int_{-\infty}^{+\infty} \epsilon^{-t^2} \phi \left\{ x + 2\sqrt{az}\,t \right\} dl,$$

containing, of course, an arbitrary function which corresponds to the constant in ordinary differential equations of one variable. It is not at first sight easy to prove the above solution, but it can be easily done by the "separation of the symbols of operation," as it is called. The solution given above is due to Laplace, and is probably the only one which is of any use in physical inquiries. If the state of the bar when $t = 0$ be given, the arbitrary function—namely, $\phi(x)$, is given, and the definite interval gives the temperature of any point of the bar at any time. Taking the simplest possible case, let $\phi(x) = ax + b$, then $y = ax + b$, throughout all time. I need scarcely say that $y = ax + b$, is a solution of the equation in question.—W. C. E.

[56605.]—**Waggon Wheels.**—"Coal Merchant's" query is difficult to answer without seeing the two waggons, but I will help him if I can. If the two sets of wheels are the same dish all he has to do is to drive the boxes out of wheels and change them, and put best set of wheels under best body. If his wheels are not the same dish, he must alter the lease of the arms to suit dish of wheels, or he will soon see his horses lose flesh.—H. J. HUMPHREY.

[56622.]—**Lightning Conductors.**—My last answer might be judiciously extended. As regards the points, they should be gilded or be of platinum. Then it would be most advantageous, if possible, to fix the bottom of the conductor to the water mains. If, however, this cannot be done, use metal earth plates in the coke. The area of these should be at least 7ft. total. Do not use insulation at supports and holdfasts. The putting up of a lightning conductor is an operation which requires much care, as a badly put up one is more dangerous than not having one at all.—J. RANCE.

[56628.]—**Heliograph.**—I am much obliged to "Volunteer Signaller" for his reply to my question; but I think he has not quite understood my difficulty. I have seen illustrations of the heliograph constructed as he describes; but I want to know how the proper angle at which to set the mirror so that the reflected ray may fall upon the distant station of the observer, is found without the aid of a sextant, an angle which is altering every moment as the sun moves onward.—ARTIBUS MAGISTER.

[56650.]—**Lead Burning.**—Mr. Davies is rather too hard, I think, on a new beginner, and Mr. D. is not quite correct about the quality of acid required, as I have seen thousands of feet burned with brown vitriol. If "New Beginner" has not the back numbers to look at, or if he wants any further information, I will write again any time. I may now inform him that the best thing for new hands at lead burning is to mind the following points:—1st. Have good clean gas, by using clean zinc free from iron, wire, &c., and free from paint. 2nd. Renew the acid and water as often as the gas begins to burn dirty and tarnish the bright lead. 3rd. Mind not to have the flame too large. 4th. Learn to burn flat work first. 5th. Start with moderately thick lead, say, 7lb. per foot, at first, and by practice he will manage 1lb. per foot lead. 6th. When he begins to burn upright nail two pieces of lead (well cleaned) on to a loose board, then he can incline the board and the lead half upright, and by degrees he can place the board quite erect. 7th. When burning upright do not have the top lap so close to the under one, and the flame and heat will go behind and heat all alike. 8th. When making the flame right size for upright or flat work, shut the air or bellows tap while you regulate the gas up to the right quantity of gas you think you need; then begin to turn the bellows tap on by degrees, just knocking it a little with a shave hook. 9th. Have a mug or pot, put plenty of clean zinc in, then try different proportions of acid and water in; you will soon learn what proportions make the most gas. Much depends on the strength of the raw acid; but if it be full strength 170 Twaddle, about one of acid to three or four water will answer best, or try acid and water at 20 Twaddle. Write again if you need more instruction, and if you or any of our kind readers can answer my inquiry made four weeks ago—viz., how to make the best nitrate of iron, without putting copperas in, for calico dyers, which stands about 78° Twaddle, kindly do so.—HENRY HOLMES.

[56651.]—**Boiler.**—I presume that the fire was damped the whole length of the furnace and the damper close shut; if such was the case, the explosion was due to an accumulation of coal gas in the furnace tubes. This would arise from the damper being close shut and only admitting a very limited quantity of air to the furnace, which would be chiefly consumed by the under side of the damped fire, very little passing through the furnace; the heat thus generated will distil some of the coals on the upper surface into coal gas, the gas will accumulate in the furnace tube because there are no currents to carry it into the chimney, and become mixed with the little air that has found its way through the furnace, making a very explosive compound, which, as soon as the stoker broke the fire, would explode. To remedy this, a portion of the grate bars at fire-bridge end of the furnace (about one quarter the length of the grate will do) should be raked clear of the fire, leaving the bars entirely open, the remainder of the fire should be damped in the usual way; the damper should also be left partially open. This will cause a current of air through the back end of the furnace, which will carry with it any gas that is generated in the damped fire up the chimney, thus preventing any accumulation and all risk of explosion.—R. W., Newcastle-on-Tyne.

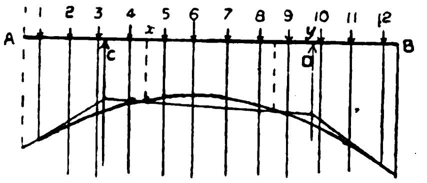
[56669.]—**Expansion of Metals.**—The increase of volume of any metal is proportional to the increase of temperature. Twisden gives the coefficients of linear expansion for 1° F. at 0·00000642 for wrought iron and 0·00001052 for brass rods; that is, the rods would increase these fractions of their original length for every increase in temperature of 1° F. Then a rod of wrought iron 36in. long heated from 32° F. to 100° F. would be—

$$36 \times 0{\cdot}00000642 \times (100 - 32) + 36$$
$$= 36{\cdot}02505616\text{in. long.}$$

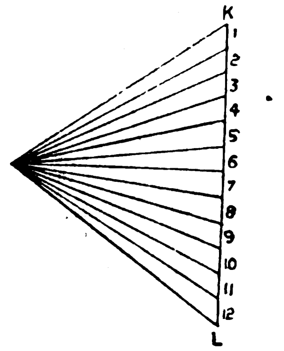
—R. W., Newcastle-on-Tyne.

[56654.]—**Portraiture.**—This is rather a difficult query to answer, because of insufficient data. for instance, querist says he uses one of Lancaster's ¼-plate landscape lenses. Now I will be bound Mr. Lancaster sells at least three different kinds of landscape or view lenses. Therefore "Camera" should state precisely what lens he uses. Presuming it to be a single lens, I should guess (what a lot of guessing indefinite queries cause) the aperture of lens without stop (other than the fixed one) would not be less than $\left(\frac{f}{32}\right)$. With such he should get a correctly-exposed negative of a group outdoors in two seconds. Then, taking ratio given in answer by "B.Sc.," 1 to 30, he would require one minute indoors, which I should consider about right. What does Mr. Bennett mean by "your negatives are under-exposed? You get the details of the dress, if a dark one, all right; but you get the faces, which are lighter, too dark in the negative, which makes them print without sufficient detail in the print"? Is there not a slip here of some sort? Since "Camera" says, "I get detail in the dress, but the features come out dark." Now this looks to me like over-exposure, since with under exposure the face would be too dense in the negative, and too white (or light) in the print; at the same time detail in the dark dress would be conspicuous by its absence. Farther on Mr. Bennett says: "It is not very easy to get good portraits with a view-lens." Quite right, Mr. B.; 'tis not very easy with any lens, but 'tis quite as easy with a view-lens as it is with a portrait-lens. A rapid rectilinear is no doubt a view-lens, and I have taken good portraits in an ordinary room with such aperture of stop $\left(\frac{f}{16}\right)$ in five seconds. Now don't say that was because it was a "rapid" lens, for rapidity depends not on any particular build of lens, but on the relation the aperture bears to the focal length; therefore, a single lens with stop $\left(\frac{f}{16}\right)$ would work quite as quick as a rapid or portrait-lens stopped down in the same ratio. "B.Sc." gave 25 seconds with a portrait-lens. Did he use the full aperture? I can get good results in two seconds in an ordinary room under the same conditions. I see "B.Sc." has omitted one very important factor in his explanation as to the why a near object takes longer to impress its image on the plate. I mean the different ratio the focal length of a lens bears to its aperture when used on a near object. For instance, take a lens of 6in. equivalent power and 1in. aperture $\left(\frac{f}{6}\right)$, use it to get a large head on a ¼-plate, and you will find that the focussing screen is about 9in. from the lens, so that our working aperture would be diminished to $\left(\frac{f}{9}\right)$ with same lens and same stop. I hope photographic querists will in future use the simple formula $\left(\frac{\text{focal length}}{\text{aperture}}\right)$ in describing their lenses, and not fuss about their being view or portrait-lenses, snap shutter, &c.—JAS. ADAMS.

[56679.]—**Supported Beam.**—The points will be best determined by the graphic method. Taking the beam as one uniformly loaded, A B represents

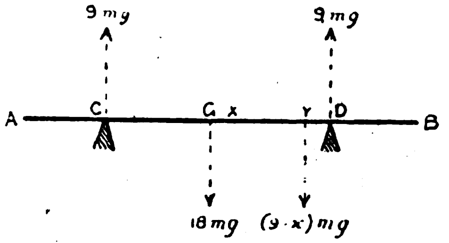


the beam resting on the supports C and D. Draw the diagram of bending moments, and the points $x$ and $y$, at which the beam has no bending moment, are the points at which it has no tendency to break.



If you wish to know the distance of $x$ and $y$ from C and D, you can measure it with the same scale as you draw the beam A B.—R. W., Newcastle-on-Tyne.

[56679.]—**Supported Beam.**—The tendency to break at any point of a beam is usually measured by what is called the "breaking couple"—i.e., the moment round the point of all the forces which act on either segment of the beam. Let A B be the beam, G its centre, C and D the points at which it is supported. Let the mass of unit length (an inch) of the beam be $m$; then it is clear that the beam is in equilibrium under the action of a force

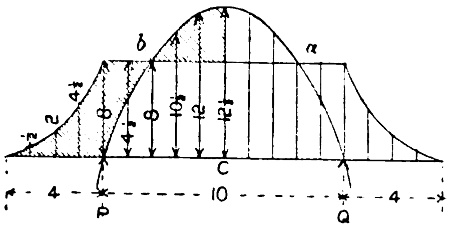


18$mg$ acting vertically downwards at G, and two upward pressures at C and D each equal to 9 $mg$. Let us find the tendency to break at any point X. Let G X = $x$. The forces which act on X B are 9$mg$ upwards at D and $(9 - x)mg$, which is X B, downwards at Y the middle point of X B. Taking moments round X, tendency to break is—

$$9mg\,.\,\text{XD} - (9 - x)mg\,.\,\text{XY}$$
$$\text{Or } 9mg\,(5 - x) - (9 - x)^2\,\frac{mg}{2}$$

$\therefore$ if there is no tendency to break $9\,(5 - x) = \frac{1}{2}\,(9 - x)^2$
Or simplifying $x^2 = 9$, $\therefore x = \pm 3$,
And the two points required are at a distance of 3in. from G, one on each side.—HIMICUS.

[56679.]—**Supported Beam.**—The bar being uniform, its weight is 18 units uniform. The weight of the parts beyond P and Q is 4. The weight between P and Q is 10. The bending moment at P and Q is weight 4 × arm 2 = 8, beyond P and Q bending moments are as the ordinates of the curve. Between P and Q there is a uniform tension in the top of the beam, and a uniform compression in the bottom of the beam, both being represented by 8. The bending moment at C for the length 10 is $\frac{10 \times 10}{8} = 12\frac{1}{2}$, between C and P, and between C and Q the bending moments are as the ordinates of the parabola, causing compression in the top and tension in the bottom, represented by the value of the ordinates, so that at the points *a* and *b* the tension in the top neutralises the compression in the top, and the compression in the bottom neutralises the tension in the bottom; that is, there are no horizontal strains at these points. But there are vertical shearing strains represented by 3 (half the weight between *a* and *b*) at each point. The ordinates in the shaded part of the diagram exactly represent the value of the horizontal strains at any point. See Professor Cotterell's "Applied Mechanics," published by Macmillan.—J. S. C.



[56681.]—**Trueing Steel Square.**—First make the stock of the square perfectly parallel; then obtain a piece of wood not less than 7in. wide and about a foot long—a piece of hard wood will be best. Get this planed up on one side, and make one edge as straight as you possibly can, for on this will depend the truth of the square. Now apply the square to this board, keeping the stock close to the straightened edge, and with a thin-edged knife make a light scratch on the planed side of the board. Turn the square upside down, and again apply it to the board. If the edge of the blade coincide with the scratch the square is true; if it does not do so, the blade must be filed down until the scratch made with one side of the blade will coincide with the scratch made with the other side, taking great care at the same time to keep the edge of the blade straight. If the blade is now made parallel, the square will be true.—R. W., Newcastle-on-Tyne.

[56682.]—**Struck by Lightning.**—"A Brand Plucked from the Burning" may be thankful he escaped with his life. His whole nervous system has had a severe shock, and anomalous symptoms such as he describes are common sequelæ of such accidents. He requires either a nerve stimulant or a nerve sedative—probably the latter; but it would be impossible to say which without a personal inspection. Probably potassii bromidum in 20-grain doses might relieve his pains; but let him beware of taking quack nostrums and narcotics, such as opium, except under professional advice, and trust as much as possible to tincture of time.—Medicinæ Doctor.

[56687.]—**Wheel Calculations.**—The wheels A and C being of the same size, no alteration of the diameters will make any difference in the velocity ratio. C will make two revolutions to one of the handle; getting one revolution from the handle and the other from the rolling of wheel B on A.—R. W., Newcastle-on-Tyne.

[56687.]—**Wheel Calculations.**—In my reply last week, I find that I was in error through misunderstanding the query. The size of the wheel B is immaterial. It is only an intermediate which derives its motion from the fixed wheel A, and communicates it to the wheel C.

$$\therefore \frac{\text{The fixed wheel A}\ 50}{\text{The wheel C}\ 50} + 1 = 2 \text{ rev. of C.}$$

—J. Jewsbury.

[56690.]—**Flux for Alumina.**—If it is desired to fuse the alumina as such, I know of no substance which will be of any use; but if something be wanted which will combine with it to form a more readily fusible compound, an alkaline carbonate would be all that is necessary.—B. B.

[56690.]—**Flux for Alumina.**—"Ex-Garrison Gunner" can dissolve pure alumina to almost any extent at the heat he mentions by adding a little at a time to ordinary borax in an open fire. The borax being volatile is gradually dissipated at this heat, leaving a very hard, transparent substance behind, which scratches glass with ease. This may be an abnormal aluminium pyro-borate; but if the product and additions be weighed, the former will be found to be minus the weight of the original borax. Besides, undeniable aluminium borate, obtained by treating pure alumina directly with pure boric acid before the blowpipe, is a white opaque, rounded mass, which no amount of ordinary heat can render transparent. In the year 1871, at Mussoorie, India, with the view of ascertaining the cause of the beautiful cerulean blue of sapphire, which "Ex-G. G." probably knows is pure alumina, I dissolved chemically prepared, perfectly white alumina, added by degrees to borax on platinum wire with the mouth blowpipe, working hours every day for a fortnight, when I obtained a pale, but distinctly and beautifully, blue transparent bead, so hard and tough that it resisted hammering on an anvil. I kept this bead for some years, but when I found no one was the least interested in the fact I threw it away, or lost it; but my experiments then convinced me that the blue colour of sapphire is due to the same cause as the cerulean blue of deep seas (over 100 fathoms), or of the miles of moist atmosphere called "the sky"—viz., to combined, or "chemical" water, which may be dissolved in ordinary water, or other menstruum. In 1879 I again "returned to the charge," and by using substances containing large proportions of this "chemical water"—namely, hydrated aluminium phosphate (pure wavellite) dissolved in hydrated boric acid before the blowpipe by a minute addition of potassium hydrate, I obtained, in about an hour's time for each, beautiful dark blue "stones," one of which I had set in a gold ring, and showed in 1880 to Professor Tyndall; no doubt he remembers the fact. By altering the proportions I obtained from the same materials brilliant green "stones," as finely coloured as the best emeralds, and a dull purple; but the latter only opaque, as it became first blue, and then green, when transparent and cool. I cannot make them so well now for want of practice; but have some tolerable ones in this exhibition, "South Central Gallery, No. 2176."—W. A. Ross.

[56697.]—**Cutting Glass Bottles.**—Soak some worsted or darning cotton in turpentine or other inflammable liquid, and wind it round where the bottle is required to be cut, then set light to it, being careful that the whole of the cotton becomes ignited, and then plunge into cold water. I have cut some very thick bottles by this method.—A. J. Wilson.

[56697.]—**Cutting Glass Bottles.**—A simple and very effective method, which I have practised for years, is to take about as much worsted as will go twice round the bottle, dip it in paraffin oil for a moment, then tie it round where it has to be broken off, take a lighted match and set the worsted on fire. As soon as it is burnt out, pour some cold water over it, and the bottle separates at once.—R. N.

[56697.]—**Cutting Glass Bottles.**—If "Sodium" will take the bottle in one hand and a hot poker (dull red) in the other, and place the end of that poker on the edge of the neck of that bottle, he will soon see a small crack. Now keep the poker about half an inch in front of the end of that crack, and it will follow the poker wherever you like to lead it. Keep two pokers going. Knocking the neck off the bottle will assist in commencing the crack, which is the only difficulty. Fill up with turpentine.—Tredagh.

[56697.]—**Cutting Glass Bottles.**—Perhaps this may suit "Sodium,"—a good plan I saw the other day, which I tried and found to answer. Take the glass bottle, which must be quite dry inside (if not it will crack where you do not want it), and hold it over a gas flame, just touching; keep turning it round until it is hot enough, you will find out in a few trials, then touch it with the point of a small brush dipped in cold water at the spot you have heated, and it will crack all round and drop off.—J. Aigburth.

[56697.]—**Cutting Glass Bottles.**—I have not heard of the method mentioned; but should think it might answer, though not with any great degree of certainty. You might try some other inflammable liquid lighter than, and not miscible with, water—e.g., ether. I have heard that by filing a groove and tying a piece of string soaked in spirit round it, and then igniting it, the object can be obtained; but this is tedious, and destructive to files. I have myself succeeded in a precisely similar case by starting a crack at the mouth (by means of the wards of a key, or a slight blow, or sudden heat), and leading it spirally down to the desired point, and then right round by means of a red-hot wire, or tang of a file, or the fused end of a piece of hard glass tube.—B. B.

[56697.]—**Cutting Glass Bottles.**—I would inform "Sodium" how I have succeeded in separating the necks from the lower parts of bottles, having done many for rough purposes. First, heat a part near the neck, and suddenly cool in water; this will start a flaw, which can be carried where you require; then, as a guide, stick a slip of paper round the bottle where you want to cut it, take a fairly-pointed poker heated, and lead the crack or flaw (which will follow a red-hot point) gradually (not directly down) towards the paper, and then continue round to meet. In gardening, to strike cuttings, old oil-flasks treated in this way and washed with hot soda-water are most useful. I have made and used great numbers, and seldom lose a cutting under one of these inverted glasses. —W. Hosken.

[56697.]—**Cutting Glass Bottles.**—I haven't tried the way the American paper gives, but should think it would answer if done properly. The following is a simpler plan, however, and I have cut off dozens of bottle-tops this way, so I can answer for its efficacy. Wind a piece of thick knitting-cotton (any absorbent kind of string will do, but I find this answers best) saturated in spirits of wine round the bottle at the point where you want it to crack off; it is not necessary to tie it, as it will stick to the bottle when wet of its own accord. Have ready a basin of water as cold as you can get it, and having set the cotton on fire, let it burn for a few minutes, holding the bottle sideways (so that only the rim, round which the cotton is wound, gets hot), and plunge it suddenly, before the cotton has burnt itself out, into the water in such a way that the surface of the cold water will just come up to the line of cotton. The glass will crack instantly, and the top will go down to the bottom of the basin. If the cotton is wound straight this makes a perfectly straight break. The rim can be afterwards filed off if considered too sharp.—R. A. R. Bennett, Walton Manor Lodge, Oxford.

[56699.]—**Condensing Engine.**—If I might offer my advice to this querist, I should say, With your present stock of information respecting steam-engines, don't have anything to do with a condensing engine—i.e., if you have any respect for your own and other people's safety or your employer's property; but rather get some good work on the steam-engine, and study that till you get the theory: the rest will come with time and practice. If you like to communicate with me, I will lend you a little book which will give you more information than could be given on a page of the "E. M."—R. A. Goodman, Stanley Mill, Marsh, Huddersfield.

[56699.]—**Condensing Engine.**—As the ostensible object of these pages is to afford information, I have very much pleasure in briefly endeavouring to make the many points clear to this querist, and (with the permission of the Editor) any further ones he may feel requisite to thoroughly understand the matter. Your present high-pressure engine delivers the exhaust into the exhaust pipe against a pressure of about 14·75lb. on the square inch, or, as we will call it, 15lb.; this is a constant back pressure against the engine which the condenser in great part removes. Now supposing that, for instance, your present engine was to be made a condensing one, what should we need to do? In the first place, we should want a suitable vessel, say, of cast iron, for our condenser itself; to the top of this we connect our exhaust pipe, instead of taking it to the outer air. Into the side, so that it projects well inside this vessel or condenser, we fit a pipe, either perforated in the part which runs across the condenser, or, still better, a rose-head or jet pointing upwards. From this pipe or jet we connect on a pipe to some body of cold water, such as a brook, or river, or canal, or even to a large reservoir. All we want is a connection so that we can draw water from an unfailing source. To the bottom of our condenser we fit our outlet, and connect it to the air-pump, a foot-valve being placed between the condenser and the pump. Our pump is arranged to be driven from the crank-shaft, and we have all the parts needed to make the engine a condensing one. Supposing we now wish to see the action of these parts, we start our engine, and we find that as the steam passes by the exhaust into the condenser it is met by the jet of cold water inside from the rose-head or jet, and is instantly condensed. Perhaps you will ask why do we get a jet of water flowing into the condenser when the water in the pond or brook is perhaps 4ft. below the level of our condenser?—simply by the vacuum we have obtained. In other words, the pressure of the air on the water in our pond is, as we have said before, nearly 15lb.; whilst in the condenser, the pressure being perhaps only equal to 2lb., leaves a pressure of 13lb. available to force water into our condenser. As the steam from the cylinder meets the jet of cold water, it is instantly condensed and falls to the bottom, from whence it is drawn off by the air-pump at each outstroke. Now, steam contains a large volume of air in solution, and this is removed by the air-pump with the injection water and the condensed steam. A stop-valve on the injection gives us the power of regulating the supply of cold water. Now, in reply to your separate questions, I would say that the vacuum is shown by a dial gauge, very much like a steam gauge; but, instead of showing pressure, shows vacuum, so that by a glance at the gauge we see when the best vacuum is gained, and it also tells us when the injection water is in sufficient quantity. This is done by gradually reducing the supply of injection water, when the gauge will show more and more vacuum until a point is reached when the best obtainable vacuum is good, and the least quantity of injection used to produce it. The vacuum being derived from the removal of the pressure of the atmosphere, is just the same in a 1-horse or 1,000-horse engine condenser. Neither does the pressure of steam enter into the question beyond the fact that the higher the steam pressure, the more injection water is needed, because the hotter the steam, the more cold water is needed to cool it. But this is only in such narrow limits that it need not trouble you. To your question on lines 8 and 9, the answer is already given. To your last, the difference between the jet and the surface condenser is this: In the jet form the water is brought into direct contact with the steam to condense it. In the surface form a large number of small tubes are used, fixed in the ends of a box or case; through these tubes cold water is driven by a pump, consequently the outer surfaces of these tubes are kept cool. The exhaust steam, instead of being sent into a condenser as in the jet form, is sent into the spaces between and around the tubes, these tubes being kept cold by the cold water passing through condenser; the steam, which is condensed steam, is drawn off with the air by an air-pump, as with a jet condenser. Thus water from the hot well (which is the cistern or tank on the delivery of the air-pump) of a jet condenser is mixed with muddy or salt water from the injection, whilst the water from the hot well of a surface condensing engine is pure water, the cooling water, which may be as dirty as may be, not coming in contact with it. The whole question is one of interest to mechanics, and I would strongly advise you to buy such a book as Dr. Lardner's "Rudimentary Treatise on the Steam Engine," price 1s.; or, better still, Mr. Michael Reynolds's book, "Stationary Engine Driving," price 4s. 6d. This latter is a modern book of great value, as a plain, concise, yet thoroughly practical handbook. The subject is one you should study, and you will, if you take the same interest in such subjects as I do, feel many hours of gratification in the perusal of such manuals.—Invicta.

[56701.] — **Pull of Martini-Henry.** — Unless the querist is a good mechanic, I would advise him to take his rifle to the armourer-sergeant, or to a gunsmith, to get the pull altered. He would do well also to remember that, although a minimum pull of 6lb. is allowed in shooting, yet it is not safe practically to go too near to that limit, because the pull of a rifle is apt to vary slightly, and it is not pleasant to be disqualified for having too light a pull. It seems to be overlooked that what is termed the "pull" of a rifle is really made up of two perfectly distinct things: 1, the pressure needed to move the trigger; 2, the distance through which the trigger moves before the cartridge is struck.—Wm. John Grey, F.C.S., hon. sec. Derwent Rifle Club, Newcastle-on-Tyne.

[56701.]—**Pull of M.H. Rifle.**—To "Inner." Take out the trigger spring and file a little off the under side of it—very little. You may make the pull as light as you wish by the above means. I may mention that this is not according to W.O. regulations. The W.O. order is to scrape a little off the bent of the tumbler with a special steel tool. It would not be easy to explain to you how the scraping is done, and if well explained, you would then even find it a most difficult job. I have altered scores of pulls by filing the spring; but you ought to get a spring-balance, such as are sold in the ironmongers for 2s., and before you alter the pull put the hook of the spring-balance on the trigger, rest the muzzle of the rifle on a table, then pull the balance, which will show you the weight of pull. Of course, you put the action in the firing position before the test. After filing the spring, test again. I write only on M.H. rifles made on strictly military plans, and only on those in use up to 1st of April, 1885. There are a number of so-called M.H. rifles made by private makers. I have seen several, and I found they differ in little details from the military one, so that my instructions may not always apply. I make the above remarks because I don't wish to mislead, nor to write about what I don't understand.—Armourer.

[56703.]—**Algebraical Problem.**—We have from the data—

$$(1)\quad \frac{n\,.\,\overline{n-1}\ldots\overline{n-r+2}\,.\,\overline{n-r+1}}{n\,.\,\overline{n-1}\ldots\overline{n-r+2}} = \frac{10}{1}.$$

$$(2)\quad \frac{n\,.\,\overline{n-1}\ldots\overline{n-r+2}\,.\,\overline{n-r+1}}{1\,.\,2\,.\,3\ldots\overline{r-1}\,.\,r.} \times \frac{1\,.\,2\,.\,3\ldots\overline{r-1}}{n\,.\,\overline{n-1}\ldots\overline{n-r+2}} + \frac{5}{3}.$$

Divide (1) by (2)—

Then $\frac{1\,.\,2\ldots\overline{r-1}\,.\,r}{1\,.\,2\ldots\overline{r-1}} = \frac{10\times 3}{5}$; or $r = 6$.

Again writing 6 for $r$ in equation (1)—

$$\frac{n\,.\,\overline{n-1}\ldots\overline{n-4}\,.\,\overline{n-5}}{n\,.\,\overline{n-1}\ldots\overline{n-4}} = \frac{10}{1};$$

hence, $n - 5 = 10$, or $n = 15$.—W. A. S.

[56703.]—**Algebraical Problem.**—No. of permutation of $n$ things taken $r$ at a time is

$$n\,(n-1)\ \ldots\ldots\ldots\ldots\ (n-r+1)$$

and taken $r - 1$ at a time—

$$n\,(n-1)\ \ldots\ldots\ldots\ldots\ (n-r+2)$$

and since these quantities are in the ratio 10 : 1 we have $n - r + 1 = 10$ ........................ (i.)

Again, No. of combinations of $n$ things taken $r$ at a time is $\frac{n\,!}{r\,!\,(n-r)\,!}$

and taken $r - 1$ at a time $\frac{n\,!}{(r-1)\,!\,(n-r+1)\,!}$

and these quantities are in the ratio 5 : 3.

$$\therefore\ \frac{(r-1)\,!\,(n-r+1)\,!}{r\,!\,(n-r)\,!} = \frac{n-r+1}{r}$$

$$= \tfrac{5}{3}\ \ldots\ldots\ldots\ldots\ (ii.)$$

From equations (i.) and (ii.) we have $n = 15$, $r = 6$. East Anglian.

[56703.]—**Algebraical Problem.**—The number of variations, or permutations, according to Todhunter, of $n$ things taken $r$ at a time is—

$$n\,(n-1)\,(n-2)\ \ldots\ldots\ldots(n-r+1).$$

The number taken $r - 1$ at a time will be the same as above, except that it will not contain the last term. Hence by the conditions of the problem this last term must = 10, and we get—

$$n - r = 9\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(1)$$

Again, the number of combinations of $n$ things taken $r$ at a time is—

$$\frac{n\,(n-1)\,(n-2)\ \ldots\ldots\ldots(n-r+1)}{\underline{|r}}$$

The number taken $r - 1$ at a time will have its numerator only one-tenth as great, and its denominator will be factorial $r - 1$ instead of factorial $r$. Hence we have—

$$\frac{10}{\underline{|r}} : \frac{1}{\underline{|r-1}} :: 5 : 3.$$

$$\therefore\ 30\,\underline{|r-1} = 5\,\underline{|r}$$

whence $r = 6$ and from (1) $n = 15$. The number of variations of 15 things taken 6 at a time is 3,603,600, and taking 5 at a time the number is 360,360. The number of combinations taking 6 at a time is 5,005, and taking 5 at a time 3,003. The numbers 15 and 6, therefore, completely satisfy the conditions of the problem.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56706.] — **Microscopical.** — "Ignorant's" polariscope is all right. He will not obtain colour phenomena with the prisms only. He must introduce another double refracting body upon the stage to do that. If he will put a piece of mica or a section of wood or bone, or a prepared slide of salicine, santonine, or a fish scale in balsam, he will obtain fine colour effects. If he will look in Sale Column, he will find little paper he wants advertised. —E. Holmes.

[56706.]—**Microscopical.**—Though I do not know much about the subject, yet as I have been through a similar experience to "Ignorant," and found the way to use the polariscope without any assistance, perhaps I may be able to help him. You are perfectly right in the way you put your instrument together (mine goes in just the same way), and your description of the effect is quite correct; but there is evidently "something wanting," and that something, it seems to me, is a selection of proper objects. Perhaps you may not be aware that only certain objects are affected by polarised light, and many of these in different ways. As I understand the matter, the polariscope, consisting of two prisms, breaks up the ray of light into two parts, and as one prism is rotated the varying position of the portions of the ray bring out, in some objects, effects which could not be obtained by a ray of ordinary light. These effects are of two principal kinds—those with colour and those without. Some objects, when viewed with polarised light, present the most gorgeous changes of colour, altering with the rotation of the prism; others, though less highly coloured, show a remarkable structure known as the black cross. The second class are without colour, but details of structure are very clearly shown in bright light and deep shadow, the position of the lights and shades changing with the rotation of the prism. These are just a few of the things you may look for and expect to see. Now as to objects. I would advise you to get a few of the polariscope objects of one of the good makers, and familiarise yourself with them. Mine came from Watson and Sons, and include a transverse section of walrus whisker, which shows some of the most gorgeous colours imaginable; transverse section of whalebone, which shows the black cross. Another beautiful object is platino-cyanide of magnesium. One of the finest objects of this (chemical) class I ever saw is cinconidine. Of the second class, uncoloured objects, a very good specimen is the palate of whelk; these may be had at 1s. each. You ought also to have a set of selenite slides; they are 1s. 6d. each, but are generally sold, I think, in sets of three—blue and yellow, red and green, various; but any may be had separately. By themselves they produce no effect, but placed under or over the object on the stage, they give to many of them a splendid colouring, which changes in a most beautiful manner on rotating the prism slowly. I have found them especially effective with my palate of whelk and whalebone. I think if you get some of these and try them you will find your polariscope—as I have mine—a source of almost endless enjoyment; and you can then proceed to prepare and experiment upon crystals of various chemical salts, and other objects. If you do not find the results I have led you to expect, write again, and I will try to help you all in my power.—F. W. B.

[56708.]—**Science Questions.**—A table 1 mètre by 70 centimètres has an area of ·7 mètre$^2$; it, therefore, contains 700,000mm.$^2$, or 7,000cm.$^2$, or 70dcm.$^2$. I suppose next week we will have an inquiry as to the number of sq. in. in a table 6ft. by 4ft. (2) The volume of a gas varies inversely as the pressure. Hence we have—

530 : 770 :: 1200 : 1743 mètres$^3$.

(3) The *approximate* specific gravity of the metal is obtained by dividing its weight in air by its loss of weight in water, this last being obviously the weight of an equal bulk of water. In the case given we have—

$$\text{Sp. gr.} = \frac{3{\cdot}7395}{3{\cdot}7395 - 1{\cdot}5780} = \frac{3{\cdot}7395}{2{\cdot}1615} = 1{\cdot}73.$$

In the case of the unknown liquid, we have that the weight of a bulk of water equal to the piece of metal is 2·1615grms., and that the weight of an equal bulk of the liquid is 1·4499grm. Hence—

$$\text{Sp. gr. of liquid} = \frac{1{\cdot}4499}{2{\cdot}1615} = {\cdot}67.$$

—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56709.]—**Lubrication.**—Very much depends on the lubricator itself, as well as the lubricant. Many lubricators simply administer the oil as drops one at a time into the steam-pipe. Once in the steam-pipe part finds its way mechanically into the cylinder, and part is taken up by the heat of the steam, and is converted into vapour. Now if we follow the steam we find that the oil in solution in the steam is gradually deposited on the various metal surfaces, so that if the h.-p. cylinder and valve be well lubricated, the l.-p. cylinder and valve, which must be of larger surface, have only the remnant of the oil in solution to lubricate them. Even supposing that the high-pressure cylinder did not either absorb or decompose the entire volume. I am well aware that endless instances could be mentioned where one lubricator does the business; but, in my opinion, this is due not to the lubricant still held by the steam, but from lubrication due to partial liquefaction. Now on an actual test a Boyle's Injector Lubricator is proved to have so fed in the oil as spray of the finest subdivision that an ample volume of lubricant was carried to the l.-p. cylinder. There are (not to be unfair) others besides Boyle's that no doubt would show an equally good result; but I have no faith in those giving drops of oil only. What is the meaning of the black glutinous residues in the valve-box and cylinder but decomposed oil? Therefore, if it be decomposed, how can it be in two places and lubricate the l.-p. cylinder. If I were specifying I should undoubtedly mention a lubricator on each cylinder. Then, again, I have found that suet (not rancid) is far better than oil or tallow, so that another point is here involved. In my opinion, from actual experience, suet is better than oil or tallow, whilst I would after suet prefer a good oil. I am, of course, giving my opinion only, but based on daily use of the three forms of lubricant in question.—Invicta.

[56710.]—**Salicylic Acid in Food and Drink.** —Perhaps the best known test for this is chloride of iron. Eat or drink some of the suspected article, and three hours later test the urine. The result will be first a precipitation of phosphate of iron, and then, on adding more of the test, if salicylic acid be present, even in so small a quantity as 25 milligrams (about one-third of a grain), note the characteristic violet tinge due to this reaction.— Percy Stanley, 119, Manchester-road, Poplar, E.

[56711.]—**Fulcrum.**—The weight of the bar acts as though it were collected at the centre of gravity of the bar; that is, in the middle. We have then 4lb. acting at the middle, and 6lb. acting 5in. off at one end of the bar; consequently, the fulcrum must be between them, and 2in. from the end, since $6 \times 2 = 4 \times 3$.—W. A. S.

[56711.]—**Fulcrum.**—As the fulcrum is 10in. long and weighs 4lb., then the centre of gravity is in the middle of it, or at 5in. from one end; and as there is 6lb. at the other end, then $\frac{6 \times 5}{4 + 6} = 3$in. —that is, 3in. from the centre of the lever; or $\frac{4 \times 5}{4 + 6} = 2$in.—that is, 2in. from the 6lb., which is the point where the lever will be at rest on fulcrum. —R. N.

[56711.] — **Fulcrum.** — The centre of gravity where the weight of the bar might be concentrated is 5in. from the end. By the principle of the lever, 4lb. × its arm = 6lb. × its arm, and the length of the arms will be inversely as the weights acting on them. Dividing the length of 5in. into 10 equal parts, 4lb. × 6 of them, or 3in. = 6lb. × 4 of them, or 2in., the fulcrum will be 3in. from the centre, and 2in. from the end of the bar. Study this and similar questions in some elementary book on mechanics.—J. S. C.

[56711.]—**Fulcrum.**—On the assumption that the bar is uniform, its weight may be considered to act at its centre; hence the problem becomes one of finding the point about which a lever 5in. long, without weight itself, but with weights of 4lb. and 6lb. at its extremities, will balance. Let $x$ be the distance of the point from the 6lb. weight, then the moment of the weight about the fulcrum is $6x$ pound-inches. Again, the distance of the fulcrum from the other end is $5 - x$ inches, and the moment of the 4lb. weight is $4(5 - x)$ pound-inches. These moments are of opposite sign, so there will be equilibrium when they are numerically equal; so we get $4(5 - x) = 6x$; whence $x = 2$. That is, the point about which the lever will balance is 2in. from the 6lb. weight.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56711.]—**Fulcrum.**—This question was one of those given the Applied Mechanics Examination last month by the Science and Art Department. The bar is 10in. long and weighs 4lb. Its weight is considered to act at its centre of gravity, which is consequently 5in. from either end. Practically, therefore, the bar is reduced to a lever of the first kind, having a weight of 6lb. at one end and of 4lb. at the other, its length being assumed to be reduced to 5in. By the law of equality of moments, one weight multiplied by its distance from the fulcrum must equal the other weight multiplied by its distance from the fulcrum, and these distances are inversely as the weights, which are in the proportion of 4 to 6, or 2 to 3. Divide the 5 inches into 5 units, and divide inversely as the weights, and we get the balancing point at 2in. from the end from which the 6lb. weight is suspended.—Fred. A. Robinson.

[56711.]—**Fulcrum.**—Let $x$ = distance of fulcrum from end at which the 6lb. weight is hung. ∴ $10 - x$ = distance of the fulcrum from the other end. Then, assuming the bar to be uniform, the weight of the portion $x$ is $\frac{x}{10} \times$ 4lb., and that of the portion $10 - x$ is $\frac{10 - x}{10} \times$ 4lb. Now, since these weights may be each assumed to act from the centre of gravity of each portion, the question resolves itself into finding the balancing point of a weightless bar 10in. long, leaving suspended on one side $\frac{x}{10} \times$ 9lb. at a distance of $\frac{x}{2}$ from its fulcrum + 6lb. at a distance of $x$ from its fulcrum, and, on the other, $\frac{10 - x}{10} \times$ 4lb. at a distance of $\frac{10 - x}{2}$ from the same point. Then, as the effect of these forces at these distances must be equal—

$$\therefore \left(\frac{x}{10} \times 4\right) \frac{x}{2} + 6x = \left(\frac{10 - x}{10} \times 4\right) \frac{10 - x}{2}$$

Whence $x = 2$.—B. B.

[56718.]—**Northern Railway of France.**—The distance from Calais (Pier station) to Paris viâ Boulogne and Amiens is given in the official French time tables as 298 kilomètres, equal to 185 miles 303 yards.—R. T. L.

[56718.]—**Northern Railway of France.**—The distance from Paris to Calais (Ville) is given by the company in their timetables as 297 kilomètres—i.e., 184¼ English miles. The harbour extension is about three-quarters of a mile, so that the total distance to the pier would be 185 miles.—East Anglian.

[56721.—**Steam Motor.**—To "Invicta."—If this querist will advertise his address, I will make a communication to the necessary parties, so that he may get the information he desires. I may add that this motor seems well adapted for driving dynamo machines, and from what users seem to say is giving every satisfaction, more especially a more recent pattern, which has an improved form of inoxidisable condenser, which, in my opinion, is a decided improvement.—Invicta.

[56722.]—**Flywheel.**—I should myself recommend a disc flywheel for the speed you mention. For a pair of cylinders, 2in. bore and 4in. stroke, at 350 a minute, I should use a wheel 20in. diameter, the rim being of U section. Across the widest portion the section should be 2in. wide by 1in. deep; this whilst the minor or inner rim should be 1in. deep and 1in. wide. With the boss and disc, or arms, the weight would be about 35lb. You say what difference if boiler pressure was raised to 50lb., with the speed being the same? I should not vary the size or weight of the wheel; but if you made more or less revolutions a minute, then I should certainly alter the weight and diameter of the flywheel. 350 a minute is a high speed for engines 2in. by 4in. Is this correct?—Invicta.

[56725.]—**Western Railway of France.**—The distances from Paris to Versailles are stated in the French official time tables to be as follows:—By Rive Droit, 23 kilomètres, equal to 14 miles 514 yards; and by Rive Gauche, 18 kilomètres, or 11 miles 225 yards.—R. T. L.

[56733.]—**Problem.**—Apparently there is a misprint in this question. In line 8, 13 hours should read 3 hours. Assuming this to be the correct reading, let A. pump out $n$ gals. per minute; then, since working together, they would clear the hold in 3h. 45m., in this time A. would pump out $225n$ gals. But A. actually did pump out $200n$ gals.

$$\therefore 200n + 100 = 225n.$$

∴ A. pumps out 4 gals. per min., and B. pumps out $\frac{2}{3} \times \frac{5}{4} \times 4 = 3\frac{1}{3}$ gals. per minute. Let $x$ be number of gals. in hold at first, and $y$ number of gals. which leak in per minute. ∴ whole number of gals. pumped out when both work together is $x + 225y$.

$$\therefore (x + 225y) \div (4 + 3\tfrac{1}{3}) = 225 \quad \ldots\ldots\ldots\ldots \text{(i.)}$$

A. would empty the hold in $\frac{x}{4 - y}$ minutes. In this time B. pumps out $\frac{10x}{3(4 - y)}$ gals., and there remains $\frac{2x}{3(4-y)}$ gals.

$$\therefore \left(\frac{2x}{3(4-y)} + 200y\right) \div 4 = 200 \quad \ldots\ldots \text{(ii.)}$$

From equation (i.) and (ii.) we may determine $x$ and $y$. Thus we have—

$$y = 2,\ x = 1{,}200;\ \text{or},\ y = 5\tfrac{1}{4},\ x = 468\tfrac{3}{4}.$$

—East Anglian.

[56733.]—**Problem.**—Let $x$ = number of gallons in hold at first, $y$ = number of gallons per minute which come in at leak, and $z$ = number of gallons per minute that A. can pump. Since B. pumps $\frac{2}{3}$ as fast as A., and at each stroke throws out $\frac{5}{4}$ as much as A., ∴ B. pumps $\frac{2}{3} \times \frac{5}{4} \times z = \frac{5z}{6}$ galls. per minute. A., pumping by himself, could pump out the vessel at the rate of $(z - y)$ galls. per minute. A. would, therefore, take $\frac{x}{z - y}$ minutes to clear out the hold. B. can pump out the vessel at the rate of $\left(\frac{5z}{6} - y\right)$ gallons per minute; therefore, in $\frac{x}{z - y}$ minutes he will pump out $\frac{x\left(\frac{5y}{6} - y\right)}{z - y}$ galls., and A. would pump out what remained, or $\left\{x - \frac{x\left(\frac{5z}{6} - y\right)}{z - y}\right\}$ galls. in

$$\left\{\frac{x}{z - y} - \frac{x\left(\frac{5z}{6} - y\right)}{(z - y)^2}\right\} \text{minutes.}$$

The total time, therefore—

$$= \frac{2x}{z - y} - \frac{x\left(\frac{5z}{6} - y\right)}{(z - y)^2} = \text{13h. 20min. or 800min.}$$

Therefore (1)—

$$\frac{2x}{z - y} - \frac{x\left(\frac{5z}{6} - y\right)}{(z - y)^2} = 800.$$

If A. and B. worked together, they would pump out the vessel at the rate of $\left(z + \frac{5z}{6} - y\right) = \left(\frac{11z}{6} - y\right)$ galls. per minute; they would, therefore, empty the hold in $\frac{x}{\frac{11z}{6} - y}$ mins. = 3h. 45m., or 225 mins.

Therefore (2)— $$\frac{x}{\frac{11z}{6} - y} = 225.$$

In 225 minutes A. pumps out $225z$ galls., and B. $\frac{5z}{6} \times 225$ galls.; but $225z - \frac{5z}{6} \times 225 = 100$.

Therefore (3)— $z = \frac{8}{3}$.

Equating the values of $x$ in (1) and (2) and substituting $\frac{8}{3}$ for $z$, we get after a little reduction—

$$207y^2 - 888y = -816$$

∴ $y = 1\frac{1}{3}$ galls. per min., or 80 galls. per hour

And $x = 800$ gallons.

—J. C. Kelly.

[56734.]—**Testing Butter.**—London cream is an emulsion, made by triturating fresh butter with powdered gum-arabic, and adding milk until the right density is acquired. The ideas of London milk being calves' brains and chalk and water are exploded on account of the price of the former and the insolubility of the latter.—Basford.

[56734.]—**Testing Butter.**—The following is a useful rough-and-ready way to test the purity of butter. Take ¼oz., and dissolve it to oil in the oven, and whilst hot float a lamp wick in it; then light it; after burning some time blow it out; if pure, it will have a pleasant odour, but if mixed with animal fat you will have the characteristic pungent smell of acroleine, like an extinguished tallow candle.—W. A. S.

[56737.]—**Cutting Discs.**—No expensive machine is needed. All you want is a pair of washer cutters. These are like a pair of stout joiner's compasses; but the one leg carries a small cutting blade instead of being a mere point only. They are made so that the knife travels round in a vertical plane, so that the washers are cut with a square, not a bevelled edge.—Invicta.

[56738.]—**Wimshurst Machine.**—The granulated appearance of the sectors is produced by passing the tinfoil through prepared rollers; but Mr. Jackson and others may easily prepare any small quantity by pressing the tinfoil upon a sheet of new glass paper. The "two binding screws on the base board" are in metallic connection with the outer coatings of the Leyden jars; the removal of the wire between the binding screws breaks the outer circuit of the Leyden jars. I shall always be glad to give any further explanation, but fail to see any point open which can now be usefully touched by me; but when the winter season for electricity approaches I shall be glad to furnish through these pages all the explanations and sketches necessary to enable the amateur and others to build up similar instruments to those exhibited by me in Group 28, No. 2128. In the meantime intending makers should closely look at the parts of the machine exhibited.—James Wimshurst.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

Since our last, W. J. Grey has replied to 56204.

**Disinfection and Disinfectants.**—A committee of the American Public Health Association have issued a preliminary report on the subject of disinfection and disinfectants, in which it is explained that disinfection necessitates the actual destruction of any specific which gives rise to infectious diseases, and that the destruction must not be partial, but complete, if true disinfection is to be obtained. Popularly, the term disinfection is used in a much broader sense, and mere deodorisers and antiseptics are styled disinfectants—the result being much misapprehension and failure: many such agents are entirely without value for the destruction of disease germs. This applies, for example, to the valuable antiseptic sulphate of iron or copperas. Antiseptics, however, exercise a restraining influence upon the development of disease germs, and hence they have a proper place amongst the agents to be used for certain purposes when epidemic diseases are prevalent. Many so-called disinfectants are mere deodorisers, and quite valueless for their professed purpose. Chloride of lime is held by the Association to be entitled to the first place for disinfecting excreta; it is both trustworthy and rapid in its action. A solution of corrosive sublimate and permanganate of potash in soft water, in the proportion of two drachms of each salt to the gallon, is placed next, as being really effective, but slower in its action. Liquor sodæ chlorinatæ is also referred to, but it is dearer than chloride of lime, and has no special advantages over it. For clothing and bedding which cannot be washed, a temperature of 230° F. is recommended as sufficient for the destruction of all known disease germs which do not form spores. Superheated steam under pressure is, however, a safer method to rely on, and, as stated in the memorandum, a less temperature of this agent probably suffices to effect the object than is the case with a dry heat.

# QUERIES.

[56739.]—**Books.**—Would some of our readers kindly tell me what books would be required to read up for the examination (honours) held by the Science and Art Department, in the following subjects?—Theoretical Mechanics, Applied do., Sound, Light and Heat, Magnetism and Electricity, Physiography, Agriculture, Steam, and Hygiene.—Student.

[56740.]—**Psychology.**—Will any reader of the English Mechanic be good enough to tell me what parts of Bain's "Mental and Moral Science" I had better read for the London B.A. pass?—S. J. S. L.

[56741.]—**Shafting.**—To "Invicta" or Others.—Will "Invicta" kindly inform me the best method of setting out a line of shafting at right angles to an existing line of shafting, and 8ft. above it, to be driven by a quarter twist belt?—Another Millwright's Apprentice.

[56742.]—**G.W. Railway Locomotives.**—Can any correspondent give me the dimensions of the engine 1163? Also is there any difference between 1163, and the coupled narrow-gauge engines? Which class do the drivers like best? What are the principal dimensions of the broad gauge, six-wheel coupled engine, No. 2068?—Demoid.

[56743.]—**L. and N.W. Railway.**—What are the dimensions of "Bevere" express engine? Which are the most popular with the drivers, the simple or the compound engines? Where is the single engine "Cornwall" stationed, and what trains does it work?—Demoid.

[56744.]—**Softening Water.**—Can someone inform me (1) If any apparatus is procurable for softening water, 22° Clark temporary hardness with lime—say 2,000 or 3,000 gallons an hour? (2) If any such contrivance can be practically worked with ordinary care, by one not a professional chemist to insure reduction of the hardness to a minimum, avoiding the addition of a surplusage of lime? (3) The best practical test of the result?—J. T. C.

[56745.]—**North Eastern Engines.**—Can any correspondent give any information of the new N.E. express just built at Darlington and Gateshead? Are they still of Mr. Macdonell's design?—B.

[56746.]—**A Disagreeable Noise.**—Would any kind reader suggest a plan to remedy the following?—An old lady living opposite a smith's shop (distance, 40ft.; height, 14ft.) and she says that every blow on the anvil is like striking her on the head, especially when lying in bed (it is an iron bed). We padded the window with cloth, but it seems to have done very little good.—R. M.

[56747.]—**Governors.**—I have an engine 1⅝in. bore, and 3in. stroke, and I want it to run at about 200 revultions per minute. Will some reader kindly inform me how to make a pair of governors, stating the size and details for the same? Also what size of copper boiler (vertical one), and what thickness of copper to work at 20lb. pressure would do for the above engine? I should heat the boiler with gas.—A. B.

[56748.]—**Barbadoes.**—Will some of your readers give me some information about the above island, such as best and cheapest route to reach it, climate, &c.? Having to go on business shortly, which may detain me some time on the island, I am anxious to know? An early answer will oblige.—A. Kimber.

[56749.]—**Painter's Wheel Lining Tool.**—Would any of "ours" kindly inform about a painter's decorative wheel lining tool, and give a hint how to construct the same?—Bon-accord.

[56750.]—**Gold-Plating.**—I wish to make some small steel articles appear as if gold-plated, and stand polishing, but can't afford gold plating. Would any kind reader tell me any way to do this? Soldering thin sheet brass over them would do, but would be very tedious.—C. M.

[56751.]—**Portrait Drawing in Crayons.**—Will one of our obliging friends inform me how to enlarge photographs for crayon portraits? Also name the best kind of paper for the work, and oblige.—Invalide.

[56752.]—**Raising Water by Ejector.**—I have a town's supply of water at 40lb. pressure; in addition I have another supply of stream water. Can any reader inform me if an injector would lift the water out of stream by means of the town supply at 40lb.?—if so, what kind of ejector or elevator is best? How many feet would it raise the stream water, and how many gallons of town water at 10lb., would it take to raise each 1,000gal. of stream water, say 20ft.?—T. H. Bury.

[56753.]—**Horse-Power to Drive a Millstone.**—I have a pair of ordinary millstones, 4ft. diameter. Can any reader inform me what nominal horse-power is required to work such mill, to grind barytes and similar hard minerals?—T. H. Bury.

[56754.]—**Filtering Water.**—Will any reader inform me of a cheap and good filter that will easily purify stream water, so as to render it fit to use in making starch, which I am informed requires an extremely pure water?—T. H. Bury.

[56755.]—**Magnesia Firebricks.**—Within the last four months there has appeared, in either the English Mechanic, or one of the other technical journals, a paragraph on the mode of manufacture of these articles; but having omitted at the time to make a note of the paper in which it occurred, I am now quite unable to come across it again, although I have searched for it a great deal. Can any reader of "ours" kindly assist me? I should very much like to find it, or obtain other information on the subject, and as to where such manufacture is carried on.—Cosmopolitan.

[56756.]—**Electro-Plating.**—Will any of "ours" inform me of the method employed to silver Britannia metal and common pewter? Silver can be deposited on it from its ordinary cyanide solutions, but does not adhere sufficiently to allow of burnishing; ordinary quickening solutions too contain acid, is there any special quickening used for pewter?—if so, how is it made?—Elsby.

[56757.]—**Steam Expansion**—What is the velocity of steam escaping through an aperture of two superficial inches, with say a constant pressure of 60lb. to the square inch, and supposing it to be unopposed by atmospheric pressure?—James Sinclair.

[56758.]—**Friction Clutch.**—I should be obliged for a description of the friction clutches used in tricycles, drills, &c. They are not referred to in the indices of many years' back numbers. I mean the clutches that lay hold of the shaft when pedalling forward, and free themselves when pedalling backward.—Birmingham.

[56759.]—**Waterproofing Canvas.**—Will you kindly tell me what is the cheapest, simplest, and best method of making canvas waterproof? The canvas is that in which drapers' packages are made up in. Would size, varnish, or boiled oil do?—Rescisco.

[56760.]—**Accumulators.**—I have a small dynamo, which I can work from an engine in the daytime, but not at night. I want to make some accumulators for it, sufficient to light three five-c.p. lamps for about four hours. I should be glad if anyone would tell me the size and number of cells I should require. Can I use thin lead plates, and would they be best rolled up or flat? What is the best way to cover them with red-lead, and now can I tell when the battery is fully charged?—Plumbrom.

[56761.]—**Three-Cylinder Engines.**—Will any of your readers give descriptions and sketches of best three cylinder engines—Willans, Brotherhood's, and Halsey's, or give titles of books, giving full descriptions of them?—M. R.

[56762.]—**Safety Bicycle.**—I think of making a 40in. bicycle with side rods, something like the Facile. Would some kind reader tell me the length of crank-rods and general dimensions? A few hints on the best way to make adjustable bearings, either plain or ball, would be very acceptable. I have the use of slid-rest lathe, drilling machine, &c.—Low Flyer.

[56763.]—**Water Analysis.**—To Mr. Jno. Grey, F.C.S.—will you kindly give directions for estimating (quantitatively) the following in the solid matter, obtained by evaporating 70cc. of water:—Sulphate of calcium, sulphate of magnesia, carbonate of calcium, carbonate of magnesia, chloride of sodium, sulphate of potash. Textbooks do not give methods for estimating the lime and magnesia as carbonates or sulphates, but the total lime, magnesia, &c.—Z. Y. M.

[56764.]—**Tempering Carpenter's Tools.**—Will some reader inform me where I can get a good book explaining the right way for tempering carpenter's tools, and all fine-edge tools for cutting leather and wood, and also showing the way to temper all sorts of springs, or some hints?—Tool Worker.

[56765.]—**Polish for Walnut Table.**—Would some reader kindly advise me how I am to restore the French polishing on a walnut table, which has been rendered quite rough and dull by having eau-de-Cologne spilled on it?—A. R.

[56766.]—**Building.**—Would someone tell me what is the difference in price of building now, compared with 20 years ago? I am told that to build a cottage that could be built 20 years ago for £100, would now cost £130, as bricks and labour are dearer; but I should have thought that timber being cheaper and competition keener, it would have compensated for increase in wages and bricks.—M.

[56767.]—**Parrots.**—Would someone who understands different species of parrots advise me on the following? I sent to a bird dealer for a young ring-neck parrakeet, but had an adult bird sent me. He has never once made the least kind of noise, not even in his natural tone, but continually climbs round the cage trying to get out; at other times he will sit quite still sometimes for an hour, I should like to know whether there is any chance of making it talk—I have had it a fortnight.—Y. M.

[56768.]—**Ancient Lights.**—Would someone tell me how close I am allowed, by law, to build near a window overlooking, and if there is any difference between a clear window light used as a dwelling, and a semi-transparent window of a chapel?—X. Y. Z.

[56769.]—**Legal.**—A. engages B., in the presence of C., to give a course of twelve lessons to a pupil of A.'s on a fixed day, one lesson to be given in each week for a certain sum. After seven lessons B. requests A. to change the day, but this will not suit A.'s pupil. A. then writes B. a polite note to say change of day is impossible, upon which B. replies that he will not finish the remaining five lessons and incloses his account for seven. A. feels morally bound to pay B. for these seven lessons, but is B. legally entitled to anything?—W. H. S. M.

[56770.]—**Putty.**—Will one of my fellow readers who goes in for glaziering tell me how putty is made properly? I can make a feeble imitation by mixing up whiting and linseed oil, which are, I believe, the ingredients used; but the genuine article I cannot make a bit, and what I do make does not stick properly. Ought one to mix it up in one's hands? I wouldn't be a glazier if they get their hands in the mess I get mine in when I do it.—R. A. R. Bennett.

[56771.]—**Calico Dyeing.**—How can I make stannate of soda liquor and powder suitable for calico piece dyers, as it is wanted different for pieces from hanks?—H. Holmes.

[56772.]—**Varnish for Wall Papers.**—Any information for preparing the varnish used by paper-hanging manufacturers to coat their paper to make it waterproof? It does not stain the paper as ordinary varnish and is quite flexible when dry.—A. W. G.

[56773.]—**Glucose in Leather.**—To Mr. Allen.—The practice of weighting leather with glucose is now largely carried on. I have used the following process for its estimation, and should feel thankful to Mr. Allen if he would point out its defects or indicate a shorter course. 5grm. of leather shavings were taken: these were shaved from the edge of the belt by means of a razor, placed in a Soxleth's fat extractor with ether to dissolve out fat and to free from gallo-tannic acid. Afterwards the shavings were boiled in a test tube with distilled water on the water bath three separate times, and the three extracts mixed and made up to 200cc. with distilled water. A portion of this was filtered and a burette filled with it. I found that 5·2cc. of this extract reduced 50cc. of Pavy's solution (see "Commercial Organic Analysis," Vol. II. page 290). I calculate that this gives 19 per cent. of glucose.—Weaving Manager.

[56774.]—**Tests for 5in. O.G.'s.**—To Mr. Sadler or "F.R.A.S."—Would either of these observers kindly give me a few tests for a good o. g. of 5in. aperture and inform me if there is any reliable formula for ascertaining the light-grasping power of such an o. g., and if so, to whose magnitude scale does it apply? I suppose all the objects in the late Mr. Webb's book are given in Smyth's scale.—H. A.

[56775.]—**Small Gas-Engines.**—To "Invicta."—I think it would materially improve your proposition with reference to amateurs making their own gas engines, if you included all subscribers to the "E. M." (whether they be amateurs or not) who can prove they have been such for, say, twelve months, or for any length of time that you might think fit? I think we should all of us, both subscribers and publishers, reap a benefit thereby, and thereby increase the circulation of the "E. M." I have been a subscriber to the "E. M." for several years, mostly for the purpose of gleaning something about gas-engines; and ever since those papers appeared on gas-engines some time since in the "E. M.," I have been anxiously looking for the promised instructions how to make one; and as I do a little work at the lathe during my spare time, and the only available power at my disposal has to come out of my own muscles, I should take it as a great boon if either you, "J.H.", or any other subscriber could furnish us the required information. I think myself that a small power gas-engine might be made without infringing on anybody's patent right, because for my own use, if I could run an engine, say ½-h.p., at 4d. per hour for an hour or two occasionally, I should be very thankful, and should not grumble at the expense; and 4d. per hour for a ½-h.p. gas-engine is far in excess of the cost of some gas-engines, the patents of which have already expired.—Theo.

[56776.]—**Electro-Motor.**—To Mr. Bottone.—Thanks for sketch and description of laminated armature. I propose to make one 3in. diameter, and 5in. long. Will you kindly say how many pounds and what size wire I shall put on armature, and how many pounds of what size wire I shall put on fields to get best results? Fields will be of the ordinary flat form of core. Core of fields will be about 4in. wide—what length should they be where wire goes on? What h.p. should above motor give with 4 to 6 large-sized plunging bichromate cells? What do you think about making the laminations of malleable iron?—Electric Motor.

[56777.]—**Paste Blacking.**—Would any of your numerous readers favour with receipt for making really first-class paste blacking, and describe the mode of manufacture and packing?—X. X.

[56778.]—**Circle.**—A. and B. run round a circle in the following manner:—When starting, they run in contrary directions round the circle till they meet, A. then instantly reverses his direction, running the same way as B., the latter's speed being slowest, he is overtaken by A. at the starting point, each speed being uniform. Required the relative speed of A. and B.—Amicus Veritatus.

[56779.]—**Problem.**—Two straight lines of equal lengths, crossing each other at right angles, and intersecting at their centres, are traversed to and fro, the one by A., and the other by B., always keeping the same distance from each other, that is, half the length of the traverse; C. interposes half-way, and in a line between A. and B., and takes a certain route, still keeping an equal distance from A. and B., while preserving a straight line of A. C. and B. Required the nature of C.'s path.—Amicus Veritatus.

[56780.]—**Camping Stoves.**—Can any reader of the "E. M.," tell me which is the best stove for boating and camping, coal, charcoal, and wood being very dirty and cumbersome. I have found two small oil stoves answer better than the above. Would two methylated spirit stoves be better still, as I want to take up as little room, and be as light and least trouble possible, as there is not too much room in a boat; also which is the best and handiest lamp or lantern?—W. P.

[56781.]—**Telegram Codes.**—Are any such published?—and if so, where? I have heard of one by Dr. Algar. Is it a good one, and how procurable?—M. N.

[56782.]—**Marking Bone or Ivory.**—How are the names of manufacturers so neatly stamped on articles, such as toothbrush handles, &c.? What sort of punches are used? How applied—hot or cold? and how and with what are letters then filled? I am often asked to mark initials on such articles, but fear to crack them with ordinary steel punches.—M. N.

[56783.]—**Steam Brake for Locomotives.**—On the Continent, where the inclines are severe, it appears reverse working has been employed as a steam brake; but as the temperature of the gases in the smokebox is about 600° F., they would dry up the lubrication of the cylinder and rubbing surfaces. This difficulty, however, has been overcome, by first sending into the exhaust pipe a jet of water; the energy of the moving mass is thereby stored up in the boiler, instead of being uselessly expended in grinding the rails and destroying the tires of the wheels. I should feel obliged if anyone would give a short account of how this system has answered, and also the reasons why it has not been universally adopted on our railways?—David Stephen.

[56784.]—**Bicycle.**—The front-wheel bearings of my bicycle are so worn as to cause some vibration. They consist of balls running in two parallel grooves, corresponding grooves being cut in the spindle. They are adjustable vertically by two screws in each, the cranks are not detachable. Will any reader tell me how to remedy this?—Amateur Mechanic.

[56785.]—**Kites and Kite-Carriages.**—Can any reader give me any information as to (1) the best shape, proportion, and material for kites for drawing and guiding (*i.e.* tacking) a boat or carriage? (2) A correct method of obtaing best position and angle of belly-band? (3) Reason of undue oscillation of kite, and means of preventing same? (4) The successful use of kite-carriage being an accomplished fact, a reference to any account of the method employed, or any work obtainable containing articles on the practical and scientific principles of kite construction. N.B. I have examined works in a public library, under several likely headings, without success.—J. H. T.

[56786.]—**Mechanics.**—Will any of the readers please inform me how to solve this problem?—Draw a square A B C D, and suppose it to represent a cube of stone weighing 1,000lb., and resting on a stone floor (A B produced); through D suppose a forceP to act, tending to make the body slide in the direction B to A. Find the magnitude and direction of P, when it is the smallest force that will make the body slide?—Dumbuck.

[56787.]—**Drilling Rough Plate-Glass.**—Will someone give a description of a drill for rough plate-glass slabs?—Juno.

[56788.]—**Agglomerate Battery.**—I have several agglomerate cells, and after putting new zincs and re-charging with sal-ammoniac I get scarcely any current. Can one of "ours" tell me if I can do anything with the blocks or carbon to get a good result? The blocks have been in use three years, and have had two new zincs during that time. I want them for electric bell and indicator.—A. A

[56789.]—**Klinkerfues' Barometer.**—While repairing the case of one of these instruments or "avertisseurs" as they are called by the makers, the index has become disarranged, and as it does not fit on a square or furnished with any indicator of its proper position on the axis of the instrument, I shall be pleased if some of "ours" would kindly inform me how to re-adjust it. At present I see no way but placing it alongside of another similar apparatus of known accuracy and setting with it; and with this object shall be glad to have access to one in the vicinity of Liverpool or Manchester.—Klinkerfues.

[56790.]—**Limited Liability Company.**—What are the customary and legitimate duties of a managing director and manager?—Klinkerfues.

[56791.]—**Telephone.**—It would be a great boon to many readers of "ours" if some able expert would summarise the leading features claimed by the various patentees as protected. Can Bell claim the exclusive use of an iron diaphragm with any and every form of electro-magnet actuated by battery current or permanent magnet?—or does an alteration in the nature of the diaphragm (though necessarily armed with iron armature in centre) or different form of electro-magnet, free it from royalty? Do Gower, Ochorowicz, &c., pay a royalty?—Klinkerfues.

[56792.]—**Coal.**—Will some obliging and experienced electrician say if coal and anthracite are conductors of voltaic electricity, and to what extent?—Klinkerfues.

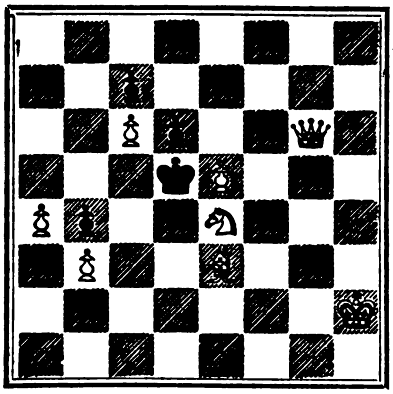
[56793.]—**Seltzogene, Leaky.**—I have one of Dr. Fevre's veritable seltzogenes for making soda water. Could anyone say what kind of cement the top is fastened on to the glass with? The top is a white metal one—are they screwed and cemented as well?—Seltzogene.

## CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

### PROBLEM DCCCCXLII.—An Easy Shave.

*Black.*



*White.* [8+4

White to play and mate in three moves.

### Solution to 940.

| *White.* | *Black.* |
|---|---|
| 1. K-Kt 8 | 1. K-K 2 or Q 2 (*a*) |
| 2. Kt takes P (dis ch) | 2. K moves |

| 2. Kt-K 8 (ch) | (*e*) 1. Any other |

### NOTICES TO CORRESPONDENTS.

Correct solutions to 939 by V. S. Pochin (easy on account of no scope for white: plan prettily intended though full of duals), G. T. Stringfellow, Brum (pretty fair for a two mover), T. L. Robins.

To 940 by R. A. Bennett, J. E. Piper, A. W. Orr (very difficult, rich, and sound), Rev. W. Anderson (Old Romney), and A. S. Olver.

To 941 by H. Culmer, F. A. Vincent, E. S., and A. S. Olver.

Streetgate.—In 941, if 1. $\frac{\qquad}{\text{R takes Kt-P}}$ 2. B covers.

Game received from F. A. Vincent.

## ANSWERS TO CORRESPONDENTS

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

### BACK NUMBERS.

We receive so many queries asking for directions how to make many instruments and appliances which have been fully described in back volumes that we have compiled a list, which we shall insert in this column at intervals, of those most frequently sent, and as the numbers are still in stock, new subscribers should consult the list before sending their questions.

Batteries: Nos. 741.
Bookbinding: Nos. 613.
Copying processes: Nos. 750, 753.
Electric machines: Nos. 628, 759, 840.
Electro-magnets: Nos. 756, 772.
Lacquers: No. 866.
Pattern Making: Nos, 938, 941, 943, 945, 948, 950, 952, 954, 955, 956, 958, 959, 962, 963, 965, 969, 973, 974, 978, 981, 986, 989, 993, 995, 998, 1,000, 1,001, 1,003 1,004, 1,008, 1,009, 1,010.
Silver-plating: No. 830.
Telephones: Nos. 695, 747, 865.
Varnishes: 478, 619, 675, 691, 723, 775.

The following are the initials, &c., of letters to hand up to Wednesday evening, June 3rd, and unacknowledged elsewhere:—

Tolley and Ticehurst.—T. Fenwick, jun.—Ellis and Co.—A. Jones.—H. Thorpe.—J. Tildesley.—British Horological Institute.—W. H. Harling.—E. P. Alexander.—C. S. Stock.—F. M. Rogers.—Dr. Edmunds.—E. A. Tindall.—Keeling and Rigley.—A. Plucknett.—B. J. Hopkins.—An Old Subscriber, Walsall.—Backwoodsman.—A. Hearn.—S. Arlidge.—Hadah.—W. B.—S. Beeching.—Ascalon.—A. H. G.—Vandusra.—G. H. Hepworth.

C. A. (Yes. Mr. Ellis Lever, of Bowdon, Cheshire, made the offer. We believe the management of the competition rests with Mr. Burt, M.P.)—E. H. (You should use a pocket battery such as that described on p. 119, No. 1,019. For directions for constructing small accumulators, see p. 28, No. 1,016.)—Undergrad. (Heat to a red; when cool, fill with sand and stop each end tightly; then bend round suitable forms. Use a wooden hammer, if necessary. We do not know of a book on that subject.)—J. S. (They can, if they like, bring an action against you; and if they have a good case, very likely will. If you have a good case, you can stop their threats by bringing an action against them; but before doing anything of that kind, consult a solicitor. If you had a partner with money, you would probably hear nothing of the threats.)—C. H. Thompson. (There are practical difficulties which, so far as we can see, it is impossible to overcome. Why not submit your ideas to a firm of engineers? If presented in a comprehensible shape, they would, no doubt, receive attention. The advantage of utilising nearly the whole of the available heat of the fuel is unquestionable; but at present you have not explained how that is to be done.)—J. Thompson. (Celluloid is, we believe, used. See the indices, however, for much information on the subject.)—Nimnim. (Try the common shellac cement, or if that won't do, marine glue.)—Onus Probandi. (What connection has your letter with the subject? Pinchbeck is an alloy of copper and zinc; but the metal referred to in the query contained gold, silver, copper, and palladium. Information about that was asked for. If you can supply it, by all means send it on.)—W. E. S. (It is specially-prepared paint, and it is frequently rubbed down with glass-paper and pumice-stone until a perfectly smooth surface is obtained. For your purpose, filter the paint through canvas, and put on in very thin coats with good brushes, letting each coat dry thoroughly hard before rubbing down. Work of the kind is usually finished with stoving copal and, so to speak, japanned in an oven.)—A Sufferer. (Frequent bathing in the hottest water that can be borne has been recommended. Some suggest the addition of bran or hay to the water.)—J. W. (Perhaps he does not intend to publish it.)—John Bayley. (The question has been frequently answered. You must fill the holes with oil—force it in, in fact. See p. 262.)—An Inquirer. (The simplest is ice and salt—two parts of pounded ice to one part of salt. If ice cannot be obtained, a cheap mixture is sulphate of soda 8 parts, hydrochloric acid 5 parts.)—M. C. Z. (Put such a question to Mr. D. Nutt, bookseller, Strand, W.C. There is not much demand for books of the kind.)—Dale. (Absolutely worthless.)—J. W. Elphic. (Probably copies; but, as you were told by the directors of the National Gallery, no opinion could be given worth having by one who had not seen them.)—T. R. Allinson. (You cannot do it. The American conscience as to copyright is a bad one. You can only secure your object by arranging with some American publisher for publication on the same day as in England.—P. Le Neve Foster. (Inserted; but Italian stamps are of no use here. Send a Post Office order.)—Edward Harrison. (We are not a sporting prophet.)—Esau. (All depilatories contain lime or arsenic, and are dangerous. Here is as harmless a one as any: Sulphate of arsenic, 1oz.; quicklime, 10oz.; starch, 14oz. Well mix into a stiff paste with water, and allow a little to remain on the skin for a few minutes.)—Leo. (Freckles may be removed by a teaspoonful of hydrochloric acid, and 1 fluid ounce of rectified spirit. Mix with 8 fluid ounces of water.)

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 12s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. James W. Queen and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., and XL., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## CHARGES FOR ADVERTISING.

| | s. d. |
|---|---|
| Thirty Words .. .. .. .. .. .. .. | [illegible] |
| Every additional eight words .. .. .. .. | [illegible] |

Front Page Advertisements Five Shillings for the first [illegible] words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. d. |
|---|---|
| Twenty-four words .. .. .. .. .. .. | [illegible] |
| For every succeeding Eight Words .. .. .. | [illegible] |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. d. |
|---|---|
| Sixteen words .. .. .. .. .. .. .. | [illegible] |
| For every succeeding Eight words .. .. .. | [illegible] |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Epps's Cocoa.**—Grateful and Comforting.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists, London."—Also makers of Epps's Chocolate Essence

**Holloway's Ointment** is not only fitted for healing sores, wounds, and relieving external ailments, but rubbed upon the abdomen it acts as a derivative, and thus displays the utmost salutary influence in stomachic disorders, derangements of the liver, irregularities of the bowels, and other intestine inconveniences which mar man's comfort.

**J. THEOBALD AND CO.'S LATEST SPECIALITY.—THE AMATEUR'S PHOTOGRAPHIC CAMERA,** for Instantaneous Photography.

THE widespread interest created by the excellent exhibits of Photographic Apparatus at the INTERNATIONAL INVENTIONS EXHIBITION, and the ever-increasing demand for something really practical, and yet cheap, has induced us to at last bring out the

**AMATEUR'S CAMERA,**

which is the outcome of nearly two years of study and experiments. It has been easy enough to manufacture Photographic Apparatus, but a far different thing to bring out a really good article, at a price that would meet the wants and pockets of amateurs. We have now succeeded, however, but wish it to be thoroughly understood that nothing short of a sale of some thousands will enable us to make them and sell them at the price. We cannot afford to lose money, which we shall certainly do if only a few dozens are sold. Consequently, we will only undertake to execute orders that reach us within 28 days. This will give us sufficient time to see if the demand will pay, and if it does not, we shall then stop the sale. We, however, believe that the demand will be enormous: otherwise this advertisement would never have appeared. With this Camera persons can photograph their friends, pet animals, houses, scenery, &c. It is often inconvenient for one to have to dress and go to a photographer's at a certain time. All this is now done away with. Whenever you feel inclined to take a person's photograph, or have your own taken, bring out the Camera, and it is done at once. To avoid all misunderstanding, let it be understood this Camera will *really take photographs*, not simply copy them; and all chemicals, &c., are given with it. Do not confound this with other Cameras, which, although advertised at much *higher prices*, yet have no accessories, but after you get the Camera you have to spend a large sum of money for chemicals and other apparatus. This one we sell is *complete*.

The Amateur's Photographic Camera measures 6in. square, and consists of a strong, well-made Camera, powerful Lens, Brass Fittings, Brass Cap, Focussing Tube, Dark Shutter and Slide, Focussing Glass, Packet of Dry Plates, Packet of Sensitised Papers, two Bottles of Developing Solution, Bottle Gold Solution. Box of Fixing Crystals, Cards for Mounting, Printing Frame, Elastic Bands, Glass Roller, and full instructions complete. Carriage free, 15s. This apparatus will really take perfect Photographs indoors or outdoors. For Travellers, Bicyclists who wish to carry away with them views of lovely spots they visit, for Ladies and Gentlemen, for Mechanics for taking Photographs of Models, and for a thousand and one other things, these Cameras are unrivalled. Specimen of Portrait taken, post free, six stamps.

All orders must be sent within 28 days (except from abroad), and customers will oblige by sending the Coupon below with their order.

ENGLISH MECHANIC COUPON.
Entitles holder to 1 Amateur Camera for 15s. if sent within 28 days.
(Signed) J. THEOBALD and CO.

Two will be sent, Carriage free, for 28s.

Novelties and Inventions of every description. Established over fifty years. Telephone 3,218.—J. THEOBALD and CO., 6 and 7, Bath-place, Kensington High-street. Kensington, London, W.

**£200 GIVEN AWAY!**

**A NOVEL COMPETITION!**

**A Simple Bible Question!**

**An Easy Chance for Old and Young!**

We offer Premiums to above amount to the 217 persons correctly answering the following simple question: **WHERE IN THE BIBLE IS THE WORD "MIRTH" FIRST MENTIONED?**

No person will be entitled to participate in our rewards unless answer to above question is accompanied by an order for the GOLDEN ARGOSY, on following terms: One Year, 8s.; Six Months, 4s.; Three Months, 2s. post paid, to your address.

To the first answering correctly, on or before July 1st, we will give £50; if we receive more than one correct answer, we will give to Second, £30; Third, £20; Fourth £15; Fifth, £10; Sixth, £5; and to the next 200, each, a Standard Dictionary, containing over 900 pages, and 80,000 references. If you are not first, you may be second, third, fourth, fifth or sixth, so **YOU STAND A GOOD CHANCE FOR A LARGE PRIZE.**

In order to please all, we offer the following:

**CONSOLATION REWARDS**

1st, £10; 2 to 11, each, Shakespere Complete. The above list of Consolation Awards will be given to the last 11 persons answering our Bible question correctly. We enter every letter in the same order as received, and number the names as recorded in our subscription books. Hence there can be no mistake. If you do not get one of the first, you may get one of the last list of awards. If you don't get anything but our Paper you will still be well satisfied, as it has no equal at the price. In all respects The Golden Argosy is a first-class publication, with large, beautifully printed pages, handsome illustrations, interesting short and serial stories, poetry, sketches, &c. Sample copies post free, Three half-pence, or all news stands. Everything is carried out as promised, as our thousands of subscribers will say. We refer to all of them. Remit by P.O., Stamps, or Registered Letter. Address—

THE GOLDEN ARGOSY,
13A, SALISBURY SQUARE, FLEET ST.,
LONDON, E.C.

**Launch Engines**. large and small, single and double, for sale.—John Middleton, 16, Hope-street, Glasgow.

**Lathes**. screw-cutting, 5in. centres, £16 ; 4in. centres, £14.—John Middleton, 16, Hope-street, Glasgow.

**Dynamo and Arc Lamp**, 2,000 c.-p., both new, 50 volts, 15 to 20 ampères, price £18.—George Tolman, Wolverhampton.

"**English Mechanic**."—Any back number, 3d. Indexes, 6d. Vols., 2s. 6d.—T. Sladen, 33, Cank-street, Leicester.

**Lawn Mower**, 11in., good condition, £2, carriage paid.—W. Harthup, Junior, Hurst-green, Sussex.

**H. Jones and Co.** for Polishes, Varnishes, Stains, Glues, &c., &c., &c. Virgin Cork, 16s. 6d. per cwt., any quantity. Methylated Spirit, 3s. 1d. gallon.

**Stylographic Pens**, 2s. 1d. free ; usual price, 5s. ; warranted.—H. Jones and Co., Viaduct-street, London, E.

First-class 3in. centre screw-cutting **Lathe**, cheap.—Particulars of A. Halls, Howard-street, Yarmouth.

Two new **Vice Pins** and solid boxes, suit 5in. vices, 10s. each.—Halls, Howard-street, Yarmouth.

**Piles**.—Worst cases cured first application. Indian Ointment, sent ten stamps.—Thomas Palmer, St. Helen's, Auckland, Durham.

**Devonshire Cream** (delicious) by improved centrifugal process. ½lb., free, 1s. 6d.—G. Bull, Manor Farm, Martock, Somerset.

**Fresh Butter** of superior quality from the cream, as above. 2½lb., free, 3s. 6d.

Genuine **Syrup Recipe**.—Coughs, Colds, Consumptive tendencies, 18 stamps ; poor person, 7.—Beta, Y. M. C. A., Bradford, Yorkshire.

**Telegraphy**.—Learners' sets, sounder, and key, and battery, P.O. Pattern 30s.—Sledge, Wyatt, and Co., Clapham.

**Telegraphy**.—Learners' Sets. S.N. instrument and Battery, 30s., free on receipt of cash.—S. W. and Co.

**Telegraphy**. — Sounder and key, full size (P.O. pattern), on mahogany boards, 30s. set.—S. W. and Co.

**Telegraphy**.—Telegraphic Clerks should purchase a set for home practice.—Sledge, Wyatt, and Co., Clapham.

**Telegraphy**.—SLEDGE, WYATT, and CO. (late of L. Clark, Muirhead, and Co., of Westminster), 95, Wirtemburg-street, Clapham.

**Sixpenny Telegrams**.—Before entering the Telegraph service have home practice with your own instruments.

**Telegraphy**.—Every set warranted complete, and sent free on receipt of P.O.—Sledge, Wyatt, and Co., Clapham.

**Sledge, Wyatt and Co.**, Electrical Engineers, are making these sets expressly for students of telegraphy.

**Incandescent Lamps**.—A few Woodhouse and Rawson, 50 volt, never used, at 2s. each.—Sledge, Wyatt, and Co.

**Quotations** forwarded to Amateurs for all electric work.—Sledge, Wyatt, and Co., 95, Wirtemburg-street, Clapham.

Vols. VI., VII., "**English Mechanic**," monthly parts, good. Highest offer.—G. Wessley, Waterloo-road, Aldershot.

**Mica Cut** for all purposes.—G. C. JOHNSON, 87, New Oxford-street, W.C.

An **Altazimuth** for sale.—For description and price apply, W., Bradninch Vicarage, Cullompton.

**Vermilion**, best, 2s. 4d. lb.—PINNELL BROTHERS, 214, Whitechapel-road, London, E.

**Pyrotechny**.—Complete and valuable plant, the property of the well known author "Practicus," offered at very moderate cost.—Apply to J. Bacon, Coldash, Newbury.

**Medical Coil**, large size, by Dale, new, owner has no use for it, bargain, 25s.—Apply, G. Martin, 100, Russell-road, Wimbledon, Surrey.

50in. Coventry Machinist "**Roadster**," good condition, new suspension saddle, 75s.—A. Pledger, Ely.

**Assay Balance**, Oertling, short beam, new, cheap.—As below.

Dollond **Telescope**, 3in., three eyepieces, new.

**Lathe**, 3in., screw-cutting, slide-rest, cheap.

**Microscope**, Bulloch's Biological, two eyepieces, condenser, swinging substage.—H. P., East Howle, Ferry-hill.

**Mystery Gold**.—Warranted equal in appearance and wear to nine-carat gold. See opinions of press.

**Mystery Gold** is causing a great revolution in the jewellery trade. See articles in daily newspapers.

**Mystery Gold**.—I am now supplying heavy Alberts (ladies' or gents') at 3s. 6d. each, post free.

**Mystery Gold**.—Notice.—I do not sell these Alberts as gold, but a most wonderful imitation.

**Mystery Gold**.—For Albert, send Postal Order to W. E. Russell, 10, Judd-street, London, W.C.

Green's Patent **Lawn Mower**, 20-inch cut, throw-out gear, as new, £4.—East, Market Rasen.

**Ward's Division Plate**, new series, registered, 7 rows, for bicycle makers.—Olga Villa, Hurlingham-lane, Fulham.

**No more Bad Work**.—Possessors of Lathes should have one above wonderfully cheap tool, free, 13 stamps.

**100ft. Glass**, cut to size, 12s. 6d. Pamphlet on Polariscope, three stamps.—Holmes, 149, Essex-road.

**Burmese Gong**, brought from the Naga Hills, Upper Assam.—W. Griffiths, 22, Annandale-road, Greenwich, S.E.

**Conjuring**.—Rare chance for buyers. Clearing out stock ; also fit-up. Write for list.—Postmaster, Emsworth, Hants.

**Mesmerism**.—Full manuscript instructions, 2s. Raphael's Manuscript. Private instructions for students. Thirty pages, 4s.—Postmaster, Emsworth.

**Ventriloquism**.—Rare Bargains.—Two new knee figures, 15s. Two second-hand ditto larger, 20s.—Postmaster, Emsworth.

**Ventriloquism**.—Four new figures, splendid movements.—Judge, Man, Woman, Policeman. Cost £5, sacrifice 70s. —Postmaster, Emsworth.

**Ventriloquism**.—Little Girl sits or stands, 16s. Nigger throws back head when laughing, 16s.—Postmaster, Emsworth.

**Chiromancy**.—Character read at a glance. Chart, with explanation, 7d.—H. Dyke, 21, North-street, Taunton.

A handsome **Aquarium**, 20 by 12 by 13 deep, with slate bottom, outlet pipe, decorated gold and black, perfectly watertight, 20s.—Smith, 72, Halliwell-road, Bolton.

Amateurs' second-hand **Photographic Apparatus** bought, exchanged, or sold.—Kemp and Co., Infirmary-street, Edinburgh.

Second-hand **Cameras**, Lenses, Stands, and complete photographic outfits. Send for special list.—Kemp, see above.

Induction and **Shocking Coils**, Cells. Amateurs supplied with parts for making bell sets, 12s. 6d.—See above.

**Chemical**. Physical, and Electrical Outfits for Schools and Science teachers ; Static Apparatus greatly reduced. —See above.

If you want cheap and good **Scientific Apparatus** send to Kemp and Co. stating your requirements.

Splendid double-action **Slide-Valve Cylinders** (brass), with steel screws and valve regulating adjustment, inch stroke, 6s.

These **Cylinders** are of highest quality only, and best metal ; others at considerately lower prices.

**Parts Fitted up** at cheap rates. Castings, with all parts turned, from 8s.—J. Spencer, Modeller, 1, Whittaker-street, Burnley.

5 by 4 bellows **Camera and view lens**, 25s. ; quarter-plate portrait lens, Horne Thornthwaite, 21s.—99, City-road.

Also **Model Yacht** ("May Fly"), mahogany built, 4ft. long, 40s. Small Slide Valve Marine Engine, 17s. 6d.

**Lathe Tool Holders**, 3s. ; Tools, 4d. : much handier than solid tools.—S. Brechin, Mareham-le-Fen, Boston.

**Bicycle**, 54in., superior make, Æolus balls throughout, Harrington's Enamel, and plated ; splendid machine.—Jno. Alcock, 66, High-street, Northwich, Cheshire.

**Uranotype Paper**, 6d. sheet. Cyanotype Paper 4d. sheet ; list free.—Humphreys, 44, Cornwallis-road, Holloway, London.

Order your **Photographic Apparatus** of the maker ; Drawings worked to, and ideas worked out.—Cusworth.

**Amateurs Assisted** in Photographic Apparatus, parts supplied ; write for Quotations.—Cusworth, 38, Ellington-street, Barnsbury, London.

**Wrought Iron Coils**, any shape and length. Stocks and Dies, Whitworth or Gas ; Weather Vane, new patent, shows direction of wind indoors ; Wheels, Machine Moulded, Spur, Bevel, Mortise, or Helical, in iron or steel.—F. M. Rogers, 21, Finsbury-pavement.

Small **Arc Lamps**, work with small dynamo, 100 c.p., carriage free, 6s.—Habgood.

**Wheatstone's Bridges**, accurate, 3s. 6d., carriage free.—W. Habgood, Hazlebrook, Buccleuch-road, West Dulwich, London, S.E.

**Engine and Boiler**, 2½ H.-P. horizontal, tubular upright, in thorough condition ; price £30.—G. H., 36, Hayle's-street, St. George's-road, S.E.

**Lathe**, 5in. screw-cutting gap bed, foot or steam, overhead motion, complete, price £18.—G. H., 36, Hayle's-street, St. George's-road, S.E.

**Universal Trade** and Amateur Supply.—Lecture requisites ; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—Caplatzi.

**Model Engines**, Boats, Boilers, Gauges, Cylinders Screws, and Bolts ; Fittings, new, second-hand ; cheapness unequalled ; ¼ to 2h.p.

**Fairs, Public Shows**.—Electric and Weighing Machines, Camera Obscuras, Polyramas, Lung Testers, large Telescopes, Mechanical Models ; great attractions.

**Photography**.—Large quantities of Wet and Dry Plate Apparatus, Lenses, Instantographs, Copying Cameras, Tents, Stands, Focussing Glasses, Printing Materials ; cheapest in London.

Catalogue, 2d. **Caplatzi**, Science Depot, Hire and Exchange, Chenies-street, Tottenham-court-road. See 15 years' advertisements.

**Lenses**, to form Negative Astro. Eyepieces of power, ¼ inch, 4s. Ditto Pancratic Astro., 2s. 6d.—Wm. Nicholl, Roslea, Clones.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, JUNE* 12, 1885.

## TOOLS AND CUTTER BARS.—III.

OF cutter bars a great number have appeared, each claiming some superiority over its compeers. Some are made to hold special tools, as, for instance, gouges and chisels for wood, and Holtzapffel brought out an effective one for this purpose many years ago which answered perfectly, but had the one drawback of some loose parts liable to get lost. It is, perhaps, impossible without such loose pieces to make one bar take variously-sized gouges or chisels, nor is it difficult, on the other hand, to design such a bar if these loose parts are not objected to. I have one, the maker of which I do not now recollect, but I have a vague notion it was by Booth, of Dublin, which is so similar to Haydon's that I think it probably suggested to him the form which he ultimately adopted. I have drawn it in Fig. 28, A B. In this there is a loose piece to render it serviceable for the cutters of square section for metal work, and without this piece it will hold a gouge, but not very well unless it is of one special curvature. Round or square bar cutters are equally securely held in the rectangular nick on bar and its loose inner piece. The apparent drawback for which probably it was rejected by "D. H. G." is the projection of the sling, owing in a great measure to the intermediate loose part. Unless the tool is thrust up so as to stand above the level of the shank of the bar the sling will come against the work. Even this, however, depends on the distance between the line of centres and top of slide-rest, and I have myself used the bar with the same cutters that fit one of Haydon's. I have chiefly found the sling in the way during the process of grinding.

It was probably supposed that the sling alone would not hold the cutters with sufficient firmness, and therefore the loose tail piece was added to extend the length of the nick in which the cutter lies. Haydon's bar, however, proves that this piece is not necessary, as the cutters do not slip or yield in the least if the bar is properly made.

The Smith and Coventry bar (Fig. 29) already spoken of, is made right and left, and in pointing as I have done to the faulty construction of the round tool, which, when ground, presents a plan elliptical in shape, with edge varying in sharpness, it would be very absurd of me to condemn a bar which is every day doing its appointed work in the large and important shops of the inventor, and in many others. But in writing on the theory of edge tools and on the practical application of such theory, it is impossible to avoid speaking of a defect even when it may not appear of very great importance. Because a razor with nearly flat sides will do to shave with, it does not follow that it is to be recommended if one with hollow sides is to be had. In a paper, moreover, like the present, I have no interest in commending one bar and finding fault with another; the only object being to give the reader a few hints about the why and wherefore of their struction. If, then, anyone should prefer an elliptic tool to one with distinct double edges, or a Tangye bar to a Haydon, I see no reason why he should not gratify his taste. If I were to recommend anything it would be the purchase of two or three bars by different makers, each of which would, in all probability, be used as occasion might require. Fig. 30 represents another bar of Smith and Coventry's, in which the tool of a special section of steel is secured in a slot in the bolt by which it is held, aided by a notch in the washer above it. A single nut secures the cutter in exact position. The tool swivels round so as to form a right and left or a straightforward one. This, again, is no doubt a good bar, and very useful for all sorts of work, but it is plain that the upper face is at a determinate angle, which is calculated as the best average for general purposes. Perfect accuracy is, therefore, unattainable, and if in any case a different angle would be preferable, it cannot be obtained. The only possible alteration, therefore, that can be made in the cutting edges must be got by altering the amount of clearance, and this, for reasons already stated, is very limited indeed.

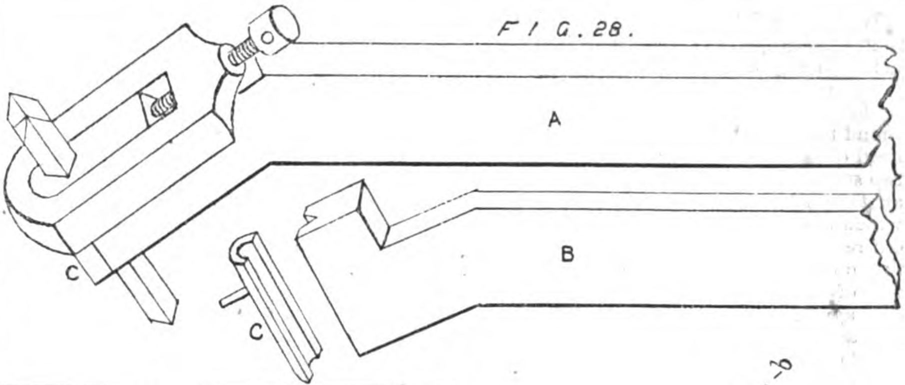

FIG. 28.

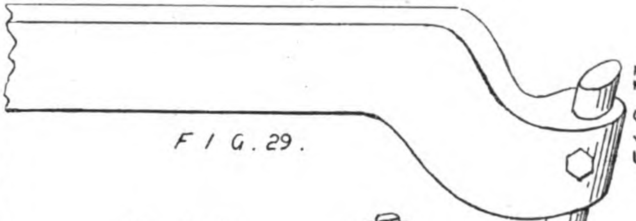

FIG. 29.

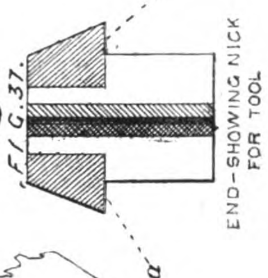

FIG. 37.

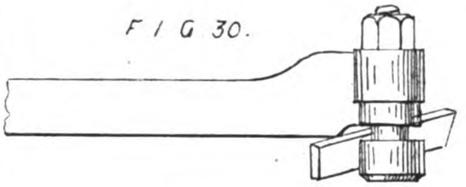

FIG. 30.

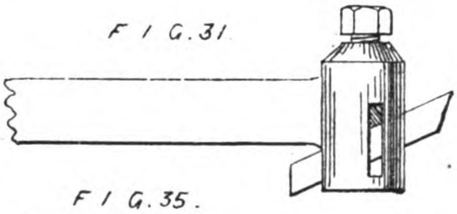

FIG. 31.

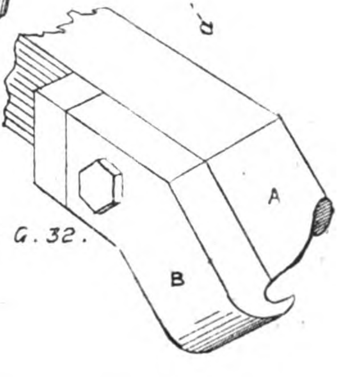

FIG. 32.

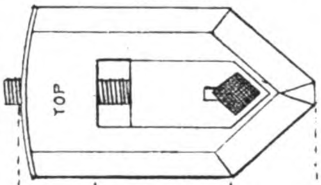

FIG. 35.

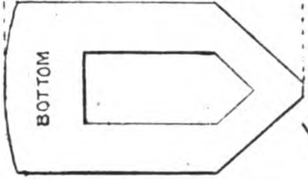

FIG. 36.

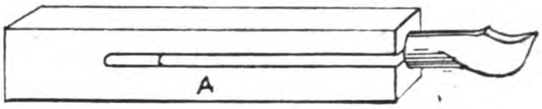

FIG. 33.

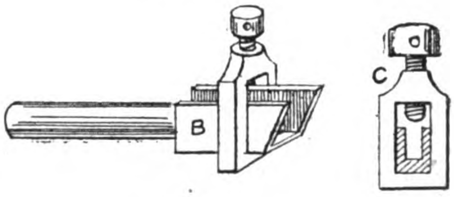

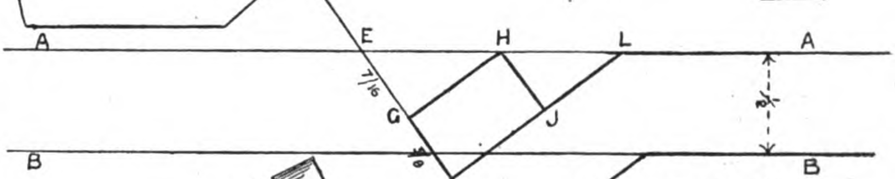

FIG. 34.

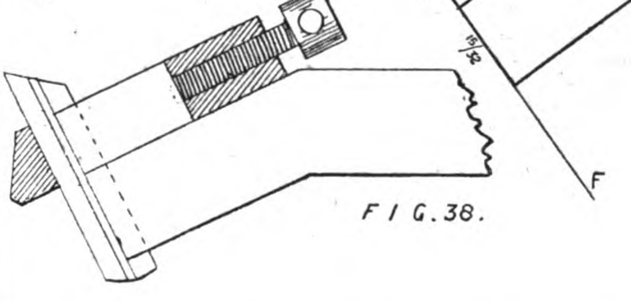

FIG. 38.

In one of Tangye's bars, derived apparently from the last, the tool is similarly held (see Fig. 31), and is, therefore, subject to the same defect. In this case, instead of a loose bolt allowing the tool to swivel round to right or left, there are slots in the head of the bar, and a pinching screw on the top secures the cutter. Here there is added another limit to the horizontal angle at which the tool can be placed; but as the entire bar can be laid in any desired position on the table of the rest, this limit is not of much practical importance. This bar, again, has the advantage of few parts, and no loose one liable to get lost. The front or clearance angle of this and the previous one can be easily ground while the tool is in the bar, as will be described in speaking of Haydon's.

My good friend "J. K. P." has sent me a bar the like of which I had not hitherto set eyes on. It appears made solely to hold a large gouge of given curvature. It is a massive affair, weighing exactly 2lb., and the tool is secured by a side clamping piece, attached by a guide pin and set screw. It must hold the gouge at a considerable rake, and, at a guess, I should imagine it to turn Elizabethan twist balusters in a large self-acting lathe — only revolving cutters would do it better. Here it is, at any rate, Fig. 32 A. B.*

Mere straight holders for round or square bar hardly come under the technical name of cutter bars; but I give a sketch of one designed by W. S. Brown, of Halesworth, because it may happen to supply a hint which may prove of value in this direction (Fig. 33.) This is a bar of steel drilled and then sawn lengthwise. The round shank of the tool slides spring-tight into this hole, and is clamped securely as soon as the pressure of the screws in the tool holder of the slide rest acts upon it. In addition to the tools with round shanks there is a little separate holder B, with its small sling for clamping short cutters. The tool receptacle is represented too large; it should be more like C to take the small cutters used in the ornamental slide-rest. The advantage of such a tool bar is not great. The tools have to be filed and shaped much as solid ones are formed, and there is little gained by being able to revolve them upon their axes, the effect of which is merely to give more or less side rake. The split bar is better as the nucleus of an inside cutter bar, and has indeed been so used, as will presently be explained when we have done with those for external work.

What is now well known as the Haydon bar remains to be described, and for simplicity of detail and undeniable correctness in principle it has not, so far as I know, been surpassed. Some supposed copies were, however, at one time sold, which, from their inaccuracy, tended to bring this bar into disrepute. Mr. Haydon, on first offering it to the notice of mechanics and amateurs, stated plainly that it was a modification of another, and was intended simply to carry out in practice the theory of cutting tools published by Prof. Willis in the first volume of Holtzapffel's valuable work. The professor had himself devised a holder similar to that for the slide-rest; but not suitable for the purpose except as an experimental one. Having thoroughly studied the subject of tool edges and the special requirements of a bar which would present cutters at a proper angle to the work, and enable them to be rigidly held, Mr. Haydon eventually adopted the bent bar and sling, modifying it so far as appeared necessary, and not forgetting that it should be within the powers of an amateur or any workman of moderate skill to construct. In this work there is really no difficulty whatever, as the rough forging can be made by any blacksmith, from a wooden pattern and zinc template; and a little care in the use of a file—if a planer is not available—will soon bring the job to a successful termination. The great thing is to go to work methodically, and not at haphazard, nor by rule of thumb, and the way thereto is as follows:—Measure the height of the lathe centres above the top plate of the slide-rest on which the bar is to lie when in use, because upon this will depend certain measurements, and it varies in different lathes. In small lathes it will probably be from ½in. to ⅝in., and in larger lathes from ⅝in. to ⅞in., or even more. Draw a line A B, Fig. 34, to represent the height of lathe centres, and a second parallel to it to represent that of the tool-plate, at the distance from the first, thus ascertained. These lines will give the thickness of the shank of the bar, and the upper one will also represent the limit of height at which the point of the cutter will stand.

The next measurements have for their object the regulation of the height of the tool-point above the sling, and also the thickness of the same, as well as the angular position of the tool. The latter consideration comes first in order, as it does in importance. The tool is to stand at 55° from the horizontal. Draw, therefore E J at that angle, cutting the two lines previously drawn. Then set off upon it the following dimensions, which vary according to the thickness of the bar, or rather according to the distance measured between the centre line and top of rest—in other words, the distance between the two parallel lines.

I give these dimensions from Mr. Haydon's own notes, but I see that in a drawing, also I believe by him, they vary somewhat. "If," says the writer, "the distance in question does not exceed ½in., set off E G $\frac{7}{16}$, and square off G H to represent the top of the sling and head (on which it lies). Then make G K ⅜ for depth of head and sling, and square off to L, to give the top of the cranked part. Draw H J at right angles to G H. Next measure from K $\frac{15}{32}$, and square off to bottom line of bar. These dimensions will allow the cutter to stand up ¼in. to ⅜in. above the top of sling and head." The measurement $\frac{15}{32}$ is evidently within a very small fraction the ½in. thickness of the bar, and is so in the rough; but after filing on the top of the bend the bed on which the sling is to rest, it will reduce the thickness probably $\frac{1}{32}$, leaving the finished bar of the dimensions given.

When the distance between the height of centre and top of slide-rest exceeds ½in., say $\frac{9}{16}$ to $\frac{11}{16}$, make the first set-off ½in., giving an elevation of ⅝ from level of sling to point of cutter, enabling a suitable tool to part an inch bar right through, and meeting most of the requirements of ordinary work. For an inch bar (where the aforesaid distance is of that amount) the measurements given are $\frac{11}{16}$, ¾, and 1in. This is a very large strong bar, suitable for lathes with steam power. A bar may be propped up by *parallel* strips of iron under the shank for occasional use on a lathe with higher centres, or for the purpose of lowering the tool in the sling to make it less liable to hitch in. The point of the tool, observe, must still be on the level of centres; but, the bar having been raised, the point will be below the top of such bar and below the point of flexure, and will give if a hitch occurs.

If a tool point is above what is called the point of flexure of a bar (or solid tool), and there should chance to be a hitch, the edge will draw in and get broken, or perhaps bend and spoil the work. But if it is below this point it will bend the tool or bar and clear itself. Hence it is always advantageous to keep the point low as regards the shank of the tool or cutter bar. In fine work I have frequently put a slip of iron under the shank and lowered the tool in its sling to the same extent. I am not myself mathematician enough to determine the point of flexure in a Haydon bar; but I apprehend that it is at some spot below its upper surface, and the tool point ought, I think, as a rule, to stand just below this. It is, however, better to lay such block or strip below the shank than to alter the bar, which is so easy to plan on the simple rule given, and specially devised by Mr. Haydon. He, however, foresaw a certain amount of difficulty in making bars for sale, owing to the variety of lathes manufactured, no standard apparently being accepted by makers as to the proper height of the tool slide in reference to the centre line. By means of parallel slips, however, either to be attached under the bar by a couple of screws, or merely laid upon the table of the rest, this difficulty may be overcome and stock bars manufactured and kept for sale. American lathes have in many cases available means for raising the tool plate of the slide rest, and in this case no packing is needed.

We now come to the sling which must not be like that of Fig. 28—round on the end. Made thus, it will not go into corners. Its form will be readily gathered from Figs. 35, 36, 37, and from the sections of it, *in situ* in Fig. 38. The bottom, Fig. 36, is to be filed quite flat, and then the edges are to be bevelled upwards (see also Fig. 37, which shews the shoulders filed on each side of the head on which the sling rests). In the bar (Fig. 28) these do not exist, and the sling is far less steady. The steel for the head—this being preferable to iron—should, says Mr. Haydon, be shear steel, faggoted on a suitable mandrel. There should be no unnecessary length in the slot where it fits the bar. The angle in the bar and sling (for reception of the cutter) should be got out quite square, and that in the bar further sawn or filed down for about $\frac{1}{16}$, as seen in Fig. 35, to insure the firm bedding of the cutter. If the angle in the sling is less than a right angle, the cutter acting as a wedge may burst it open. The end of the clamping screw should not be pointed nor the bar recessed. It should be turned quite flat to set squarely and truly against the head. The front of the sling is to be filed off at such angle as to allow it to go into a square corner when in place on its bar. If $\frac{1}{16}$, or even $\frac{1}{32}$, is left on the upper face on each side of the slot, it will suffice; because the bottom will be of full width and strength, and will bear any strain likely to come upon it, unless the angle is filed out to a degree less than a right angle.

(*To be continued.*)

## THE INTERNATIONAL INVENTIONS EXHIBITION.—VI.

### Manufacture of Textile Fabrics.

ALTHOUGH the manufacture of textile fabrics has been developed to its present high state of perfection in this country, and has contributed enormously to the commerce and wealth of the United Kingdom, it is well known that not one of the many branches into which it is divided is indigenous to these islands. The chief fibres which form the raw materials of the textile industries are cotton, flax, wool, mohair, alpaca, and silk; but from present appearances it would seem that another must be added in the shape of asbestos, a material which, known and utilised by the ancients, has latterly made enormous strides, and is steadily forcing its way into use for a variety of purposes. India was probably the home of the cotton industry, as China unquestionably was the first country in which silk was utilised in the production of a textile fabric. Flax and its uses were certainly known to the ancient Egyptians, and they were probably also highly skilled in the manipulation of wool, for while the poorer classes were invariably clothed in woollen garments, such as they were, the rich employed both cotton and wool, and the priests wore linen, woollen materials being deemed unclean, as they were liable to the attacks of insects. The dead, too, were wrapped in linen cloth, and its indestructibility by time or the ravages of the moth has left indubitable evidence that the ancient Egyptians must have been very skilful weavers. Sheep's wool, goat and camel hair, silk, and fibres of the pinna, flax, hemp, cotton, together with asbestos, and threads or wires of gold and silver, were all utilised by the ancient weavers; but the oldest known remains are those found in the Swiss Lake dwellings, supposed to belong to the Stone Age, which clearly prove that at so early a time the inhabitants of the earth had learned how to twist fibres into cords and to plait them into cloth. Weaving was certainly carried on by the ancient Greeks and Romans as a branch of trade, and from them the art gradually spread throughout Europe. Matthew Paris mentions that the ribs of people throughout the world were kept warm by the fleeces of English wool; and Edward III., observing the wealth which his neighbours were gaining by their encouragement of weavers, invited a number of Flemings and Frenchmen to come and settle in this country, which they did, and there and then established industries that have steadily progressed for five centuries. The Crusaders, too, brought back with them a knowledge of some of the Eastern arts, amongst which was probably that of damask-weaving, and before long a number of skilled craftsmen were settled in different parts, for weaving had been carried on in a coarse fashion by the natives, and they were not slow in comprehending the processes of the more skilful workers from the Netherlands. These artisans employed looms which were little more than developments of those used by the Egyptians, and it was not until the power of the steam-engine began to be recognised that the modern machines had a chance of being invented, for the simple reason that there were no tools to make them. The principles underlying the construction of cotton machinery were, however, thoroughly understood before Watt demonstrated the importance of the improvements he had made in the steam-engine, for in 1738 John Kay had invented the fly-shuttle, Robert Kay the drop box in 1760, Arkwright the water frame, and Hargreaves the spinning jenny in 1770, while Crompton combined those last-named inventions and produced the "mule" spinning frame in 1779. The machines were mostly driven by water power; but in 1785 the first steam-engine for working a cotton mill was erected by Boulton and Watt for Messrs. Robinsons, of Popplewick, Notts. From that time progress was comparatively rapid; tools were produced to the demand of the machine makers, and at the Great Exhibition of 1851 the United Kingdom astonished the world by the perfection of her machinery for manufacturing textile fabrics. No great changes in principle have been introduced since then; but there have been many improvements in details, which, combined with superior materials and workmanship, have given greater production with increased life of the machines. Although looms are much the same as they were a quarter of a century ago, so far as principle and general construction are concerned, they are being continually improved in details, the competition amongst makers materially helping in the progress. In the present exhibition Group IX. is a very inadequate representation of the manufacture of textile fabrics; but it will afford the general public an opportunity of seeing some of the wonderful machines which are now employed in the industry, though none of the branches is shown in anything like completeness, except it be asbestos weaving. A good exhibit of cotton working machines is to be found at the stand of Mr. S. Brooks, of West Gorton, Manchester; but even in his case it is not exactly feasible, or, perhaps, we should say, economical, to work some of the machines, e.g., an improved drawing frame. However, there is a ring spinning frame for twist yarn, and another for weft, a wet doubling frame, and a dry ditto, which represent the latest improvements in these important items of a cotton mill plant. A winding frame (Hill and Brown's patent) is a valuable improvement, as it dispenses with bobbins and winds the yarns on paper tubes up to any desired dimension, from ¼in. to 2in. thick (or wide) up to as much as 18in. in diameter. A very ingenious invention in this exhibit is the "Ferguslie" balling machine, which winds 190 yards of crochet cotton on each of twelve balls simultaneously, and when driven at its normal speed does the work at the rate of 250 yards per minute. Here it would be as well to mention that the machines in this group are driven at a lower speed than usual, and that several are shown operating on "endless" fabrics, whereas in real work the fabric would, of course, be wound on receiving rollers. Where so many apparatus of diverse kinds are driven by one engine, it is impossible to impart to each its normal working speed, and a mean has to be selected suitable for purposes of exhibition. One of the most interesting stands in the group, at the north end of the West Gallery, is the collection of machines illustrating in a practical manner the art of spinning asbestos as practised by Bell and Son, of Southwark-street, S.E. The machines are of the type well known in connection with cotton manufacture, but modified to suit the peculiar material. They consist of a carder, a slubbing frame, a throstle frame, a doubler, and a loom, with specimens of the raw material from different sources, and examples showing its condition after passing through the various preliminary processes. The visitor will experience one great advantage at this stand, for at all reasonable hours one of the members of the firm is in attendance ready to explain anything that may be desired in connection with this comparatively new manufacture, for until 1879 asbestos was generally mixed with cotton to form it into a sliver for spinning. In that year, however, Bell and Son discovered a means of spinning asbestos without the addition of any other fibre, and now a wide field of usefulness is opening for their products. A rough classification divides the asbestos manufacture into textile fabrics, paper and millboard, paint and cement, the first-named class comprising a great variety of useful products. Asbestos cloth, for instance, is found invaluable in Maignen's Filtre Rapide, while a sort of asbestos paper or felt will be found an excellent substitute for paper underneath carpets. Asbestos cordage and yarn, engine packing (especially the new combinations of asbestos with indiarubber and wires of soft metal), washers, and paint, are all notable introductions of the last six years or less, while asbestos lubricants, particularly "asbestoline," a combination of fine asbestos with other lubricating substances, are rapidly winning their way into favour amongst engineers, from their economy and perfect action. The United Asbestos Company, Limited, also exhibit at their stand the process of making "packing" by means of a braiding machine, a noisy, albeit ingenious, contrivance, which might have been omitted with advantage from this exhibition, especially as it is shown at several stands, Treloar and Sons, for instance, having one making coir plait, which is afterwards worked up into the familiar mats in view of the visitors. Other noisy machines are the looms, specimens of which are shown by G. Hodgson, of Bradford, working Bradford stuffs; by H. Livesey, Blackburn, weaving shirtings; and by some other exhibitors, notably Hacking and Co., of Bury, Lancashire, who exhibit their looms with four-shuttle motion for weaving checks, and an improved loom weaving trouserings. The McNary Machines Co., Lombard-street, E.C., show a straight and a circular weaving machine for the manufacture of various fabrics in wool, cotton, hemp, jute, &c. The circular machine is especially deserving of notice, as it works up hats, caps, and bags without seams. An Irish handloom is shown at work by Howell and James, of Regent-street, W., with samples of damask table linen in several stages of manufacture, and Mr. J. Etchells, of Macclesfield, exhibits a Davenport and Crossley's cross border Jacquard weaving silk handkerchiefs, &c., which requires no changing of cards, the latter being folded down as they pass through the machine in readiness to be taken up again when their turn comes. W. T. Glover and Co. exhibit at their stand James's patent doubling machine for cord and banding, which puts a twist into two, three, four, or any number of folds, either slack or tight, and deals with different sizes at the same time. The machine, for instance, has three heads, each with four spindles or bobbin holders, which are removable if a two-strand cord is required. If an end breaks, a weight inside the spindle at once stops the machine, so that one attendant can look after a large number of machines. Each head works independently, and can be altered in a moment to left or right hand twist. Several useful inventions are shown at this stand which have no special connection with the manufacture of textile fabrics—*e.g.*, Riley's piston ring, which is cut first and turned afterwards, thus securing a perfect circle,—Bell's patent rope pulley friction brake, &c. Close by is a novel device by Prof. Hele-Shaw, of the University College, Bristol, which has certainly nothing to do with textile fabrics, but which will attract much attention from mechanics and engineers. It is a sphere and roller mechanism for transmitting power, and is undoubtedly ingenious. A heavy sphere of iron is so placed between two solid pulleys and supported by others that it transmits the motion by rubbing friction in any desired direction, or in several directions at the same time, for every pulley or roller which is brought into contact with it may have its shaft at a different angle. Carding machines and card-grinding machines are shown at several stands, and Gauntlett and Co., of Trowbridge, exhibit their special machines for opening and carding hair by passing it between two revolving cylinders carrying spikes. Dickinson and Sons, of Blackburn, have at their stand a slasher sizing machine with beam press motion; and Mr. J. King, of Manchester, shows his improvements in doubling or twisting yarn in the shape of a machine which puts two twists in the thread for each revolution of the spindle. J. Farmer and Sons, of Salford, have an important exhibit, in which is a four-bowl calender, which gives as desired a chasing, glazing, or swizzing finish, an embossing finish by substituting an engraved roller for the friction bowl, and also the moiré finish. The bottom bowl is of cast iron with wrought centre, the next of paper or cotton, the third of chilled iron fitted for heating by steam or gas, and the top of paper or cotton. The machine shown is driven direct by two inclined cylinders attached to the A frame. Farmer and Lalanco's patent bleaching, washing, chloring, soaping, &c., machine is exhibited in the shape of a three-cistern size having six rollers. These hollow rollers are of copper, perforated and corrugated over their whole surface, and are connected in couples to rotary pumps, which draw the water or liquor through the cloth and cleanse it thoroughly from starch or matter used in the printing processes. When albuminous matter has been used beaters are employed, which make from six to eight blows per inch on the cloth, and effectually loosen the most glutinous particles. This principle of drawing the liquor through the cloth is found to work well with the thickest cloths, and the routine will be understood when we mention that for a print works a five-cistern machine would be used—the first being for fixing, the second for washing, the third and fourth for soaping, and the fifth for washing. In connection with this stand we notice a large-size model of Farmer's plant for treating sewage and town refuse, the most important feature in which is the patent twin cylinder apparatus for drying excrementitious matter. Five of these are, we understand, already at work in Birmingham, and it is intended to erect four others, and so deal with the whole refuse of that town by this certainly sanitary and, we believe, economical method, for the manure is valuable, and the ashes and ground clinker are utilised for making mortar and cement. Mather and Platt, of Salford, exhibit a continuous bleaching machine for use in the Thompson process. In this apparatus the cloth dips into a solution of bleaching powder of 1° Twaddle, and passes between squeezing rollers into a chamber containing carbonic acid. Here it is compelled to make a comparatively long stay, as it passes from the bottom to the top over a number of rollers. Emerging between rubber lips (to prevent diffusion of gases as much as possible) it is washed in a beater, and is pressed between two rollers, one nickel plated, the other covered with rubber. The rationale of the process is that the carbonic acid combines with the lime of the bleaching powder, and oxygen is given off in a state to effect the decolouration of the fibre. A gauge in the shape of a hollow glass ball floating in a beaker shows the workman at a glance whether he has sufficient carbonic acid in the closed chamber, as the sphere is adjusted to float on carbonic acid gas but to sink in air. The machine will bleach from 50 to 100 yards per minute. Mather and Platt also exhibit their open soaping and washing machine, in which the cloth passes over perforated copper cylinders, and is beaten by flaps of india-rubber attached to revolving cylinders. The object is to drive the water through the fabric, and so discharge the thickening materials used in printing it without any rubbing action. Another machine shown by Mather and Platt is a sampling machine for calico printers, to enable them to form a rapid judgment of the effect of various colours. The engraved copper rollers are readily adjusted with sufficient accuracy in a few seconds. and the requisite colour ink-troughs having been put into the machine, the pattern can be obtained printed in different colours in pieces about the size of a handkerchief in a very few minutes. Many of these patterns, it will be remembered, require five or six different rollers to complete them, and there is consequently a wide range of effects to be produced by the employment of various colours for different parts. The labour of setting the ordinary machines is practically prohibitive of much exhaustive experiment, but the ease and rapidity with which the sampling machine works render it a boon to calico printers. There are a variety of textile products exhibited which will attract the attention of many visitors; but even in this comparatively small group there is much to interest and instruct those who will examine what is set before them.

## ON THE COLOUR-CORRECTION OF ACHROMATIC TELESCOPES.[*]

By Wm. Harkness.

ALTHOUGH much has been written on the theory of the achromatic telescope, I am not aware that any attempt has been hitherto made to treat the colour-correction rigorously as a function of the wave-length of the light; and on that account, much obscurity, and some positive error, has crept into the textbooks on the subject.

The theory given in the following pages is based upon fundamental equations, which neglect the thickness of the lenses, as has always been done heretofore, and which suffice to give the refractive indexes to scarcely more than four places of decimals. All the subsequent operations on these equations are rigorously accurate; and it would have been useless to attempt greater precision in the refractive indexes while the thickness of the lenses is neglected. As achromatic telescopic objectives are usually composed of two lenses, rarely of three, and hardly ever of a greater number, it has been thought sufficient to write the equations in the form applicable to triple objectives; but no difficulty will be experienced in extending them to a greater number of lenses when necessary.

Our fundamental equations are—

$$\frac{1}{f} = (\mu - 1)\left\{\frac{1}{r} + \frac{1}{\rho}\right\} \quad \ldots\ldots\ldots\ldots(1)$$

$$\mu = a + b\gamma^2 + c\gamma^4 \quad \ldots\ldots\ldots\ldots(2)$$

in which—

$f$ = the principal focal distance of any lens.
$\mu$ = the refractive index of the lens.
$r$ = the radius of curvature of the first surface of the lens.
$\rho$ = the radius of curvature of the second surface of the lens.
$\lambda$ = the wave-length of the light.
$\gamma = 1 \div \lambda$.
$a\,b\,c$ = certain coefficients, determined from not less than three properly situated values of $\mu$.

Equation (2) is Cauchy's dispersion formula. Now put—

$$\frac{1}{r} + \frac{1}{\rho} = A \quad \ldots\ldots\ldots\ldots(3)$$

and suppose a series of lenses, such that—

$$\frac{1}{f_1} = (\mu_1 - 1)A_1;\ \frac{1}{f_2} = (\mu_2 - 1)A_2;\ \frac{1}{f_3} = (\mu_3 - 1)A_3 \quad \ldots\ldots\ldots\ldots(4)$$

These lenses being very thin, let them be placed in contact with each other; and let the equivalent focal distance of the whole combination be $f$. Then by a well-known optical theorem—

$$\frac{1}{f} = (\mu_1 - 1)A_1 + (\mu_2 - 1)A_2 + (\mu_3 - 1)A_3 \ldots(5)$$

Substituting the values of $\mu_1$, $\mu_2$, $\mu_3$, from equation (2), putting

$$\left.\begin{aligned} C &= A_1(a_1 - 1) + A_2(a_2 - 1) + A_3(a_3 - 1) \\ D &= A_1 b_1 + A_2 b_2 + A_3 b_3 \\ E &= A_1 c_1 + A_2 c_2 + A_3 c_3 \end{aligned}\right\} \ldots(6)$$

and arranging the terms according to the powers of $\gamma$, we have

$$f = \frac{1}{C + D\gamma^2 + E\gamma^4} \quad \ldots\ldots\ldots\ldots(7)$$

This equation expresses the relation between the focal distance of the combination and the wave-length of the light. It shows that when white light enters an objective, there will generally be an infinite number of foci situated one behind the other, and all contained between the two values of $f$, which correspond to the limiting values of $\gamma$.

For our purpose, however, it will be more convenient to consider $f$ as the ordinate, and $\gamma$ as the abscissa of a curve which we will designate as the focal curve. To investigate its properties we differentiate with respect to $f$ and $\gamma$, and obtain—

$$\frac{df}{d\gamma} = -2\gamma f^2(D + 2E\gamma^2) \quad \ldots\ldots\ldots\ldots(8)$$

Putting the left hand member of this expression equal to zero, we find—

$$\gamma^2 = -\frac{D}{2E} \quad \ldots\ldots\ldots\ldots(9)$$

Differentiating (8) a second time—

$$\frac{d^2f}{d\gamma^2} = 2f^3\gamma^2(2D + 4E\gamma^2)^2 - f^2(2D + 12E\gamma^2) \ldots\ldots\ldots\ldots(10)$$

Substituting the value of $\gamma^2$ from (9), this becomes—

$$\frac{d^2f}{d\gamma^2} = 4Df^2 \quad \ldots\ldots\ldots\ldots(11)$$

which shows that so long as D remains positive, the curve is convex towards the objective, and the value of $\gamma$ given by eqn. (9) corresponds to the minimum focal distance.

An achromatic objective, or more accurately and with greater precision, a corrected objective, is one in which all rays of the kind for which the correction is made are brought to as nearly as possible the same focus. For example, if an objective is corrected for visual purposes, then the rays which produce the greatest effect upon the human eye must all be brought as nearly as possible to the same focus; or, if the objective is corrected for photographic purposes, then the rays which act most energetically upon silver bromo-iodide must all be brought as nearly as possible to the same focus. This condition will evidently be fulfilled when the rays in question have the minimum focal distance; or, in other words, when they satisfy eqn. (9). Thus it appears that this equation determines the correction of the objective, and for that reason it will be called the achromatic equation, and the particular value of $\gamma$ which satisfies it will be designated as $\gamma_0$.

To find the relative values of $A_1$, $A_2$, $A_3$, in a corrected objective, we substitute in (9) the values of D and E from (6). The resulting expression for the middle lens is—

$$-A_2 = A_1\frac{(b_1 + 2c_1\gamma_0^2) + A_3(b_3 + 2c_3\gamma_0^2)}{(b_2 + 2c_2\gamma_0^2)} \ldots(12)$$

which shows that this lens must be of the opposite kind from the other two—that is, if the first and third lenses are convex, the middle one must be concave, or *vice versâ*.

To find the equivalent focal distance of the whole combination for the ray $\lambda_0$, (9) gives—

$$D = -2E\gamma_0^2 \quad \ldots\ldots\ldots\ldots(13)$$

Substituting this in (7)

$$f_0 = \frac{1}{C - E\gamma_0^4} \ldots\ldots\ldots\ldots(14)$$

Replacing C and E by their values from (6)

$$f_0 = \frac{1}{A_1(a_1 - c_1\gamma_0^4 - 1) + A_2(a_2 - c_2\gamma_0^4 - 1) + A_3(a_3 - c_3\gamma_0^4 - 1)} \ldots\ldots(15)$$

Substituting the value of $A_2$ from (12), and putting

$$\left.\begin{aligned} n &= \frac{A_3}{A_1} \\ L &= (a_1 - 1)(b_2 + 2c_2\gamma_0^2) - (a_2 - 1)(b_1 + 2c_1\gamma_0^2) + \gamma_0^4(b_1c_2 - b_2c_1) \\ M &= (a_3 - 1)(b_2 + 2c_2\gamma_0^2) - (a_2 - 1)(b_3 + 2c_3\gamma_0^2) + \gamma_0^4(b_3c_2 - b_2c_3) \end{aligned}\right\} \ldots(16)$$

We obtain finally

$$f = \frac{b_2 + 2c_2\gamma_0^2}{A_1(L + nM)} \ldots\ldots\ldots\ldots(17)$$

The ordinate of the focal curve for the ray $\lambda_1$ is the difference between the focal lengths of the objective for the rays $\lambda_0$ and $\lambda_1$. To find it we have—

$$\frac{1}{f_0} - \frac{1}{f_1} = (C + D\gamma_0^2 + E\gamma_0^4) - (C + D\gamma_1^2 + E\gamma_1^4) = D(\gamma_0^2 - \gamma_1^2) + E(\gamma_0^4 - \gamma_1^4) \ldots\ (18)$$

But—

$$\frac{1}{f_0} - \frac{1}{f_1} = \frac{f_1 - f_0}{f_0 f_1} \ldots\ldots\ldots\ldots(19)$$

and putting $f_1 - f_0 = \triangle f_1$, this becomes

$$\triangle f_1 = f_0 f_1\left\{\frac{1}{f_0} - \frac{1}{f_1}\right\} \ldots\ldots\ldots\ldots(20)$$

Substituting for the quantity within the brackets, its value from (18), and replacing D and E by their equivalents from (6)—

$$\triangle f_1 = f_0 f_1\left[(A_1b_1 + A_2b_2 + A_3b_3)(\gamma_0^2 - \gamma_1^2) + (A_1c_1 + A_2c_2 + A_3c_3)(\gamma_0^4 - \gamma_1^4)\right] \ldots(21)$$

Substituting the values of $A_2$ and $A_3 \div A_1$ from (12) and (16), and putting

$$\left.\begin{aligned} N &= b_1c_2 - b_2c_1 \\ P &= b_3c_2 - b_2c_3 \end{aligned}\right\} \ldots\ldots\ldots\ldots(22)$$

we obtain the important expression—

$$\triangle f_1 = A_1 f_0 f_1(\gamma_0^2 - \gamma_1^2)^2\frac{N + nP}{b_2 + 2c_2\gamma_0^2} \ldots(23)$$

If a star is viewed through a carefully-focussed achromatic telescope, and if the surface in the focus of the eyepiece is designated as the focal plane, then of the infinite number of images which eqn. (7) shows will be formed; some will be situated before, and some behind, the focal plane, but only one will coincide exactly with it. The cones of rays which form the images situated before and behind the focal plane will necessarily have a sensible diameter at their intersection with that plane, and their combined effects will be to produce a fringe of coloured light around the image of the star, as seen through the eyepiece. This fringe is the secondary spectrum, and its magnitude for light of any given wave-length will evidently depend upon the value of $\triangle f_1$. Hence, to destroy the secondary spectrum, $\triangle f_1$ must be made equal to zero.

Eqn. (23) shows that this will be the case for a triple objective when—

$$N + nP = 0 \ldots\ldots\ldots\ldots(24)$$

or, for a double objective, when—

$$N = 0 \ldots\ldots\ldots\ldots(25)$$

As yet no materials have been discovered whose physical properties are such as to satisfy these conditions. We therefore proceed to investigate what form an objective constructed of any given materials must have in order to render the secondary spectrum a minimum.

Substituting in (23) the value of $A_1$ from (17), we find—

$$\triangle f_1 = f_1(\gamma_0^2 - \gamma_1^2)^2\frac{(N + nP)}{(L + nM)} \ldots\ldots\ldots\ldots(26)$$

In the right-hand member of this equation, $n$ is the only quantity which depends upon the form of the objective. Considering it as variable, and differentiating, we obtain—

$$\frac{d(\triangle f_1)}{dn} = f_1(\gamma_0^2 - \gamma_1^2)^2\frac{PL - MN}{(L + nM)^2} \ldots(27)$$

To make $\triangle f_1$ a minimum, such a value must be attributed to $n$ as will reduce the right-hand member of (27) to zero. This condition gives at once $n = \infty$; which will be the case when $r$ and $\rho$ are both infinite, as is evident from equations (16) and (3). The objective is then reduced to two lenses and a piece of very thin plano-parallel glass. As the latter cannot appreciably affect the colour correction, it may be dismissed from further consideration; and thus it appears that from any three pieces of glass suitable for making an objective, but not fulfilling the conditions necessary for the complete destruction of the secondary spectrum, it will always be possible to select two pieces from which a double objective can be made that will be superior to any triple objective made from all three of the pieces.

The focal curve being tangent to the focal plane at the point corresponding to the wave-length $\lambda_0$, if we assume the spherical aberration to be perfectly corrected for light of all degrees of refrangibility, then the image of a star formed upon the focal plane by light of wave-length $\lambda_1$ will be a point, and the linear semidiameter of the image of the same star formed by light of wave-light $\lambda_1$, will be the semidiameter of the cone of rays of the wave-length at the point where it cuts the focal plane. Therefore, we have—

---

[*] From the *American Journal of Science*. Art. XXX., No. 105, September, 1879.

$$f_1 : a :: \triangle f_1 : s_0^{ii} \quad \text{.................} \quad (28)$$

in which $a$ is the semi-aperture of the objective, and $s_0^{ii}$ is the required semidiameter of the cone of rays of wave-length $\lambda_1$. Combining (28) with (26), we find—

$$s_0^{ii} = a\,(\gamma_0^2 - \gamma_1^2)^2\,\frac{N + nP}{L + nM} \quad \text{........} \quad (29)$$

This is the expression for a triple objective. In the case of a double one, $n$ becomes zero, and (29) reduces to

$$S_0^{ii} = a\,(\gamma_0^2 - \gamma_1^2)^2 \cdot \frac{N}{L} \quad \text{..........} \quad (30)$$

which shows that in a double objective properly connected for any given purpose the linear semidiameter of the secondary spectrum is absolutely independent both of the focal length of the combination and of the curves of its lenses; and depends solely upon the aperture of the combination and the physical properties of the materials composing it.

If a telescope armed with an achromatic eyepiece is carefully focussed upon a star, and then the image of the star is viewed through a prism held before the eyepiece, it will be seen that the eye does not adjust the focal plane tangent to the focal curve; but places it somewhat further from the objective in such wise that the plane cuts the curve in two points, which we will designate as $\gamma_m$ and $\gamma_n$. For these points we must have—

$$\frac{1}{C + D\,\gamma_m^2 + E\,\gamma_m^4} = \frac{1}{C + D\,\gamma_n^2 + E\,\gamma_n^4} \quad \text{..} \quad (31)$$

which gives

$$-\frac{D}{E} = \gamma_m^2 + \gamma_n^2 \quad \text{............} \quad (32)$$

But by (9) we have—

$$\gamma_0^2 = -\frac{D}{2E} \quad \text{............} \quad (33)$$

Combining this with (32), we find—

$$\gamma_0^2 = \tfrac{1}{2}(\gamma_m^2 + \gamma_n^2) \quad \text{........} \quad (34)$$

which gives the relation between $\gamma_0$ and any pair of points at which the focal plane may cut the focal curve.

We have next to consider how the value of $\gamma_m$ can be found, and for that purpose a method partly arithmetical and partly graphical seems most convenient. The data required are the values of $\triangle f$ for a number of different values of $\gamma$, and the relative intensity of the light at each of these values of $\gamma$. The values of $\triangle f$ must be computed by equation (26), and the relative intensity of the light may either be determined experimentally, or taken from published tables. For visual intensity, the table given by Fraunhofer may be employed; and for photographic intensity the curves published by Captain Abney contain all that is required. For the sake of definiteness, let us suppose that the valve of $\gamma_m$ is to be determined for an objective corrected for visual purposes. We begin by laying down an axis of abscissas and graduating it into a scale of wave-lengths. Here, however, it must be observed that the brightness of any part of a spectrum depends not only upon the inherent brightness of the light at that point, but also upon the degree of dispersion employed. As Fraunhofer's determinations of the relative brightness of different parts of the spectrum were made with a flint glass prism having a refractive index of 1·63 for the ray D; and as such an instrument produces much greater dispersion at the violet end of the spectrum than at the red end, it follows that our scale of wave-lengths must be not a scale of equal parts, but such a scale as existed in the spectrum employed by Fraunhofer. The wave-length of the brightest ray is approximately 5,688, and through that point in the scale and at right angles to the axis of abscissas, the axis of ordinates must be drawn. Then from the computed values of $\triangle f$ a sufficient number of points must be laid down to determine the focal curve, and that curve must be drawn. At the points whose wave-lengths correspond to the principal Fraunhofer's lines, lines must be drawn through the focal curve, parallel to the axis of ordinates, the length of each line being proportional to the relative brightness of the spectrum at the point where it is situated, and the centre of each line coinciding accurately with the focal curve. Through the extremities of these lines a closed curve must be drawn. The figure thus obtained will be termed the illumination diagram, because it exhibits the amount and distribution of the light at the focus of the objective. The eye will necessarily place the focal plane in the position where this light will produce the greatest effect on the retina, which is equivalent to saying that the focal plane must pass through the centre of gravity of the diagram. Hence, to find the position of the focal plane, we have only to cut out the diagram (which should be drawn upon rather stiff paper) and balance it upon a knife edge, held parallel to the axis of abscissas. The reciprocals of the wave-lengths of the points of intersection of the knife-edge with the focal curve will then be the values of $\gamma_m$ and $\gamma_n$.

The method just explained may be employed to determine the difference between the positions of the principal focus of the same telescope when used for different purposes. For example, if it were required to find the interval between the visual and photographic foci of a telescope, two illumination diagrams would be drawn—one for the visual, and the other for the photographic rays—and the difference between the positions of the foci plane in the two diagrams would be the required difference of foci.

As the magnitude of the secondary spectrum of a star is measured by the semi-diameter (at the point where it intersects the focal plane) of the cone of rays having the maximum focal distance, it follows that in an objective corrected for visual purposes, the secondary spectrum is diminished by the fact that the eye places the focal plane somewhat further from the objective than the apex of the focal curve. To find the amount of this diminution we remark that for light of wave-lengths corresponding to the points where the focal plane cuts the focal curve, the semi-diameter of the cone of rays is zero, while for light of any other wave-length, the semi-diameter of the cone of rays at the point where it intersects the focal plane, is proportional to the distance between that plane and the point of the focal curve corresponding to the wave-length of the light. Hence the effect of moving the focal plane into a position further from the objective than the apex of the focal curve will be to diminish $s_0^{ii}$ by a constant which is numerically equal to the value of $s_0^{ii}$ for light whose wave-length is that of the point at which the focal plane intersects the focal curve. Modifying equation (30) in accordance with these principles, it becomes—

$$s_m^{ii} = a\,[(\gamma_0^2 - \gamma_1^2)^2 - (\gamma_0^2 - \gamma_m^2)^2]\,\frac{N}{L} \quad \text{....} \quad (35)$$

in which $\gamma_m$ is the reciprocal of the wave-length corresponding to either of the two points in which the focal plane cuts the focal curve; and $s_m^{ii}$ is the semi-diameter at the point where it cuts the focal plane of the cone of rays whose wave-length is $\lambda_1$.

The exact nature of the colour correction of a telescope can be determined by placing the focal plane in a number of different positions, and observing the corresponding values of $\gamma_m$ and $\gamma_n$. These values being substituted in equation (34), several independent values of $\gamma_0$ can be deduced, the mean of which will probably be very near the truth. The conclusions reached in the preceding pages may be summed up as follows:—

1st. From any three pieces of glass suitable for making a corrected objective, but not fulfilling the conditions necessary for the complete destruction of the secondary spectrum, it will always be possible to select two pieces, from which a double objective can be made that will be superior to any triple objective made from all three of the pieces.

2nd. The colour correction of an objective is completely defined by stating the wave-length of the light for which it gives the minimum focal distance.

3rd. An objective is properly corrected for any given purpose when its minimum focal distance corresponds to rays of the wave-length, which is most efficient for that purpose. For example, in an objective corrected for visual purposes, the rays which seem brightest to the human eye should have the minimum focal distance, while in an objective intended for photographic purposes the rays which act most intensely upon silver bromo-iodide should have the minimum focal distance.

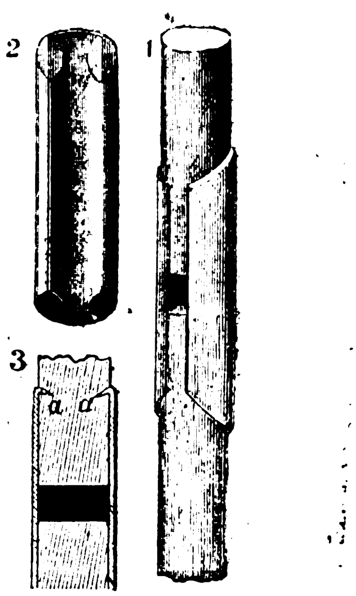
4th. In double achromatic objectives the secondary spectrum (or, in other words, the diameter at its intersection with the focal plane of the cone of rays having the maximum focal distance), is absolutely independent both of the focal length of the combination and of the curves of its lenses, and depends solely upon the aperture of the combination and the physical properties of the materials composing it.

5th. When the focal curve of an objective is known and the relative intensity for the purpose for which the objective is corrected of light of every wave-length is also known, then the exact position which the focal plane should occupy can readily be calculated.

6th. It may be remarked incidentally that in an objective corrected for photographic purposes, the interval between the maximum and minimum focal distances is less than in one corrected for visual purposes. Hence a photographic objective has less secondary spectrum, and is better adapted to spectroscopic work than a visual objective.

## LATHE BELT FASTENER.

THE invention herewith illustrated, lately patented in the United States by Mr. Lewis W. Herrick, of Edmore, Mich., belongs to that class of belt fasteners formed of a piece of sheet metal having inwardly projecting teeth on its ends, which are forced into the ends of the belt by dies. The fastening clip, Fig. 2, is made in tubular form, with one side left open to allow of the insertion of the belt. The ends of the clip are inclined from the closed side toward the open side, and the edges of these portions are bent toward the centre of the clip to form penetrating projections, *a*. The purpose of rounding the edges is to allow the ends of the belt while being inserted or withdrawn to slightly spring the projections apart, to allow of the easy entrance or withdrawal of the belt ends without the use of tools of any kind. When the end of the belt is being inserted, it will first bear against the outer rounded part of the projections, then ride up the incline until it strikes against the closed side of the clip. It will be seen that both ends are so secured that any strain put on the belt will only tend to force the ends of the belt further up the inclined projections. There will be no tendency of the belt ends to come out of the open side of the clip, and the strain will not tend to force the sides of the clip apart.—*Scientific American.*



## ELECTROLYSIS IN THE GRAPHIC ARTS.[*]

### Heliogravure.

OF all the modern methods of producing printable plates, heliogravure stands undoubtedly pre-eminent. It has many advantages over copperplate engraving, and none of its disadvantages. For heliographic reproductions the original must be extremely sharp, either a carefully-executed drawing in India ink, or a good black and otherwise perfect print of any other device. A reversed photographic negative upon glass four-fifths or three-fourths of the original size is first made. The reduction renders the lines still sharper and more delicate than in the original. A gelatine solution, to which is added sugar, lampblack, alcohol, ammonia, and creosote is then prepared, and with it a sheet of photographic paper is coated, and laid upon a plate glass carefully levelled. As soon as the gelatine mixture has set, the coated sheets are hung upon cords, and after drying, are kept in a perfectly dry room. The quantity of the pigment is proportional to the character of the original to be reproduced, one-tenth of it being the maximum, one-fortieth the minimum, the former for fine and delicate drawings in line manner, the latter for other work. The prepared pigment paper is sensitised in a bichromate of potash bath, 1—15, and laid face down upon a carefully-cleaned plate-glass, and dried in a strong current of air. Immediately before using it the paper is detached from the glass. The exposure under the reversed glass negative is made in an ordinary printing frame, the time adjudged by a Vogel photometer. After printing, the pigment paper is taken to the dark room, and in a cold-water bath transferred to a silvered copper-plate, picture side down. Removed from that bath, the paper is squeezed and dried with blotting paper. After five minutes another cold-water bath is used to wash the bichromate from the non-exposed parts. In half-an-hour it is taken up, well rinsed, and subjected to a warm water bath of 30° to 35° C. to dissolve the gelatine not acted upon, that is to develop the gelatine relief upon the silvered copper plate. After a short time the water penetrates the pores of the paper, dissolved black gelatine oozes from the film indicating the beginning of the development; in about 30 minutes the paper is detached, floats upon the surface of the bath, or can be lifted up with ease. The rest of the gelatine is dissolved in a few minutes, and the relief, a copy of the original, appears gradually upon the copper-plate. The development is continued in another bath of warm distilled water, till all remaining fog or dirt is totally removed from the interstices of the relief, and the picture stands out clear and distinct upon the plate. Finally, it is well rinsed with water and dried spontaneously.

---

[*] By Major Volkner, in *Correspondenz* (from the *Photographic Times*).

To make this relief plate conductive, powdered graphite is spread over it with tampon and a soft brush; afterwards it is placed on the kathode of a Deniell trough apparatus, and a zinc anode used to accelerate the precipitation of copper. In an hour or less the heliographic relief plate is sufficiently covered, the plate is taken up, cleaned and rinsed, and again placed in the trough. To promote the force of chemical action, caused by the electric current, an iron anode is inserted. After twenty to twenty-four days the plate will be of the desired thickness, and is, therefore, then taken from the trough, rinsed with water, and dried; the edges are filed off, and the patrix removed from the matrix. Both plates are well washed. Adhering parts of the gelatine relief are carefully removed.

If the plane of the gelatine relief has been perfectly clean, and free from any tone, the intaglio plate is also smooth, lustrous, and printable. Matt spots are wiped off with oiled flannel and rottenstone; tone and impurities are scraped and burnished; other defects, which but rarely occur, are retouched with needle and graver.

The first impressions made from heliogravure plates are always rough, and retouching them should not be undertaken till a number of prints have been made. They are in every way equal to engraved copper-plates, and with them there is a great, almost incredible, saving of time. Heliogravure plates, maps of the Austrian Empire, made in fifteen years, would have taken generations to engrave. Before large editions are printed galvanoplastic reliefs are taken from the intaglio plate. From them new copies can be made, in case the original should suffer in course of time.

### Steel-facing.

An important substitute for multiplying copperplates by galvanoplasty is to face them with steel. It is used for plates like objects of art, which never require correction. When a copper-plate is placed on the cathode, suspended in a solution of sesquichloride of iron, and subjected to the action of the galvanic current, it will in a short time be covered with a delicate and lustrous cuticle of iron, hard as steel. There is no difference seen in the prints taken from plain copper or steel-faced plates. The iron gives the plate an extraordinary durability, and many thousands of prints can be made from it. In case the steel cuticle has been unsound, it can be easily taken off and renewed. The plate is laid in sulphuric acid, diluted so much that it will not attack copper; but it loosens the steel, which blisters and comes off in scales. The plate is again washed before another steel-facing. The process is carried on in a peculiar dark trough, with a three-cell zinc-carbon battery; the electrodes are placed vertically. The suitable iron solution is made by the current. One part of chloride of ammonium is dissolved in ten parts of water, and in it are placed iron plates, as kathode and anode. When the circuit is closed a chemical action takes place, the chlorine of the chloride of ammonium unites with the iron of the anode, forming sesquichloride, which remains dissolved in the bath. Within one or two days the bath assumes a greenish colour, its surface turns red, owing to the formation of hydrate of oxide of iron from contact with air, and metallic mirror appears on the kathode. The bath is then sufficiently saturated, and in place of the iron kathode the copper plate to be steeled is inserted. The plate must, of course, be absolutely clean, and is therefore washed in caustic potash, rinsed, and any possibly adhering alkali neutralised with sulphuric acid, washed again and dried. Scamoni, of St. Petersburg, makes very durable plates by first precipitating nickel upon the silvered relief, and then allowing the copper to build up till the desired thickness is reached. His bath is: 45 parts water; 5 sulphate of nickel; and 1 to 1½ of chloride of ammonium.

### Photo-Chemigraphy.

A plate of zinc or any other metal is coated with a mixture of gum arabic, water, grape sugar, bichromate of potassium, and a few drops of ammonia, and exposed to light under a glass positive. After exposure the plate is removed to the dark room, and etched with a strong solution of perchloride of iron. Strong lines are attacked first and etched deeply, the thin and delicate parts afterwards. The process lasts but five minutes, and after cleaning it may be printed from at once. To give the plate more durability it is copper-plated and eventually steel-faced. The copper-plating of zinc cannot be done by electrotypes of the sulphate of copper: the free sulphuric acid will attack the zinc. Instead of it sub-cyanide of copper CuCy (Kupfercyamur) is used. When cyanide of potassium is added in excess to sulphate of copper, the copper electrotype Cu Cy is formed $CuSo_4 + 2KCy = CuCy + K_2SO_4 + Cy$. Sulphite of sodium added previously to the cyanide of potassium changes the cyanide into prussic acid, the sulphite of sodium into sulphate: $Cy_2 + Na_2SO_3 + H_2O = 2HCy + Na_2SO_4$. Ammonia added to the solution forms, with the prussic acid, cyanide of ammonium $NH_4Cy$. Two solutions are made, (1) 140 p. sulphate of copper, 840 p. water; (2) 140 to 200 p. cyanide of potassium, 1,000 p. of water, with the addition of sulphite of sodium and ammonia. The solutions are then mixed. The zinc plate to be copper-faced is placed on the kathode. The current is generated by two zinc-carbon elements.

### Galvano-caustics.

The electro-negative substance of the electrotype f.i., the acid of salt, or the chlorine of a chloride unites chemically with the anode, forming a soluble combination which etches the electrode. Chrom-gelatine paper is exposed under a transparency, inked with roller, and developed; the negative picture is transferred upon a copper-plate, which makes the picture metallic-lustrous. The covered parts resist etching. The sulphuric acid liberated by electrotypes combines with the copper; it etches the plate.

### In Galvanography and Stilography

the plate is coated with the fatty matter coloured with ochre or lamp-black. A drawing is made upon it with the graving tool, the plates are made conductive by graphite, and by placing them in the trough apparatus a relief is made from that on intaglio plate.

### Nature-Printing.

Natural objects like parts of plants, or laces and other open fabrics, are pressed in guttapercha or lead, and galvano-plastic matrices made from them. If f.i. lace be the object to be reproduced, it is pasted with gum upon a steel plate, a sheet of lead placed upon it, and subjected to a high pressure. Relief or intaglio plates are made this way; the former answering well for typographic printing.

### Type-Printing.

Stereotypes are now substituted by galvano-plastic copper precipitates. The form is impressed in guttapercha, the copy graphited, and, moistened with alcohol, laid in the galvano-plastic apparatus. When the copper is sufficiently thick, the plate is taken up, the reversed side and edges planed off, and backed with ordinary type-metal. Woodcuts similarly treated give galvano-plastic copies from which 70,000 to 80,000 prints can be made.

### Plain Copper-plates.

At the time when copper engravings were used exclusively in the Institute, the plates were made by the galvano.plastic process. with the aid of a twelve-cell, zinc-silver battery (system Smee). Now such plates are only made for the patrices in heliogravure. (The last daguerreotype plates in the American market were also galvanoplastic.)—TRANS.

### Magneto-electric and Dynamo-electric Machines.

Improvements introduced in the mechanical arts in modern times have also been introduced for the generation of the electric current in electrolytic operations. Magneto-electric and dynamo-electric machines have been substituted for the hydro-electric cell, by which the liberation of injurious gases and interruption of the work is entirely avoided, and more uniform and accurate work obtained. Machines for continuous currents are preferred with wire twists of considerable diameter, and wire of but little resistance, so as to generate a current great in quantity but of little intensity.

Whatever has been accomplished in the graphic arts by electrolysis justifies the prediction that there is a great future for this process. With the aid of the electric current the genius of man will continue to modify and to improve even those wonderful productions of our own times.

## THE THEORY OF THE INDICATOR: ERRORS IN INDICATOR DIAGRAMS.

AT a recent meeting of the Institution of Civil Engineers Prof. O. Reynolds, F.R.S., read a paper on "The Theory of the Indicator, and the Errors in Indicator Diagrams." The object of this paper was to define the causes and extent of the disturbances in indicator diagrams. The theory, as given, had been taught for several years in Owens College; but the publication had been deferred to enable an extensive series of experiments to be made. These experiments had now been carried out by Mr. A. W. Brightmore, Stud. Inst. C.E., late Berkeley Fellow in Owens College. In the first place it was shown that there were five principal causes of disturbance—namely, the inertia of the piston of the indicator and its attached weights; the friction of the pencil on the paper, and its attached mechanism; varying action of the spring; inertia of the drum; friction of the drum. The effect of the inertia of the pencil and its attached mechanism presented a mathematical problem, by the solution of which it was shown that there were two disturbances from this cause; one, a general enlargement of the mean indicated pressure, depending on the weight of the moving parts of the indicator, the stiffness of the spring, and the square of the speed. The other disturbance was a vibration of the pencil. Every indicator piston vibrated when disturbed, so that the period of vibration depended on the stiffness of the spring. The error which these oscillations caused in the area of the diagram depended on their magnitude, and, to a greater extent, on the smallness of the number in a revolution. But the evil of these oscillations was not so much an effect on the area as in the disfigurement and the confusion they produced in the diagram. So long as there were 30 of these oscillations in a cycle, the necessary fluid friction of the indicator piston would so far reduce them as to render a fair diagram possible, but when the number was as low as ten it was all the pencil could do to prevent them upsetting the diagram. The friction arising from the pressure of the pencil always acted to oppose the motion of the pencil, and therefore rendered it too large during expansion and exhaust, and too small during compression and admission, and thus the general effect was to increase the size of the diagram. This friction consisted of that of the pencil on the paper; and that of the mechanism, caused by sustaining the pressure of the pencil. The effect of the friction of the pencil was greatly reduced by the motion of the paper. The magnitude of these effects taken together on the area of the diagram depended on the construction of the instrument and on pencil-pressure. From numerous experiments it would appear possible to make a difference of as much as 5 per cent. in a locomotive in mid-gear by pencil-friction. The conclusions, as regarded the motion of the pencil, were that the general effect of inertia and friction were both to increase the size of the diagram; that so long as the speeds were such that the number of vibrations of the pencil during a revolution of the engine was not greater than 15, the effect of inertia was less than 1 per cent., but that if the number was greater than 30 oscillations would show themselves unless the pencil-friction was increased. They might, by this, be kept down till the number of vibrations was equal to 15, but not further, and then the necessary friction would affect the area of the diagram about 5 per cent. For the diagrams to be sensibly accurate and free from oscillation the speeds must not be greater than would make the number of vibrations equal to 30. These speeds were given in the paper for Richards' indicators. The effect of the inertia of the drum with an elastic cord was shown to be a nearly uniform elongation of the diagram. The result of the varying stiffness of the drum spring was a nearly uniform contraction. With Richards' indicator these two latter disturbances neutralised each other at a speed of 150 revolutions per minute. At other speeds the effects were apparent in the length of the diagram; but except when the expansion was great and the connecting rod short, they did not affect the indicated pressure. The friction of the drum with an elastic cord caused the cord to be longer during the forward stroke than during the backward stroke, so that the diagram was distorted and shortened, the drum being uniformly behind its proper position during the forward stroke, and before its position during the backward stroke. This distortion diminished the area of the diagram according to the rate of expansion and the length and elasticity of the cord used. This was definitely expressed by a formula. This disturbance, the influence of which was very great in cases of high expansion, large engines, and ordinary cords, appeared to have been unnoticed. The circumstances on which it depended were the elasticity of the cord and the friction of the drum, and the question was how far these existed in the ordinary indicators. It might be said that the diagrams which led to the discovery of this effect were taken with an indicator which had been in constant use for several years. It was in apparently perfect condition, and the diagrams did not differ essentially from those which had been previously taken. The cord was one which had been supplied by the maker. The manner of the discovery was described: For years the author had pursued in the class the method of testing the vibrations of the indicator pencil by projecting them on to the crank-circle, and he had noticed that the first oscillation fell short, and shorter in the back diagram than in the front. The cause of this was not obvious, and it was partly with a view to determine this cause that Mr. Brightmore's investigation was commenced. A slight error in the reducing rod, which had a fixed centre and a slot in which a stud in the slide-block worked, was altered. This, however, did not get rid of the effect. A new cord was substituted for the old one, and the effect was found to be much enhanced, the new cord being more elastic than the old one. This reduced it to the stretching of the cord, but it was only after carefully working out the effect of the inertia of the drum, and it was seen this was to lengthen the first oscillation at the back end, that the friction was examined. The indicator was taken to pieces, cleaned, and oiled: then the effect was much reduced. Several new wires and cords were used, and eventually steel wire was adopted as the best. The test supplied by the oscillations could only be applied to diagrams taken at high speeds, and the test furnished by the influence upon area was vague. What was wanted was an independent means of determining the simultaneous positions of the drum and the engine-piston. As the best method of meeting this it was decided to arrange an electric circuit through the pencil to the drum, with sufficient electromotive force to prick the paper, making the engine-piston close this circuit at eleven definite equidistant points in the motion backwards and forwards. This was successfully carried out, and the stretching of the cord during the backward and forward strokes was definitely ascertained. Taking the smallest results obtained with a cord, it appeared from these experiments that the least difference of stretching was to make this difference in inches 5 per cent. of the length of the cord in feet. Examples of this effect in diminishing the mean indicated pressure were given. Thus, in a locomotive cutting off at one-quarter it was 8 per cent.; in a condensing engine having 3·5ft. stroke, cutting off at one-tenth, 20 per cent.; and the same compounded, 10 per cent. These would seem to be the smallest results that could have occurred in ordinary practice. The conclusion, however, that hitherto the normal indicated power from engines had been from 10 to 20 per cent. too small must wait for verification. Yet there were not wanting independent evidences of such an effect. In diagrams taken from engines at high speeds the admission line would not but for this effect be vertical. It would show a certain amount of detail, and the first oscillation would not have a sharp top. Moreover, it was commonly found that the expansion line, allowing for clearance, was above the true expansion line for the steam. This apparent rise in the curve of expansion was exactly what would result if the apparent cut-off was too early, and this was the result of the effect that had been considered. The author had tried several diagrams, and found that after correction the expansion line came out very close to the true curve. In making these comparisons the explanation of another feature of diagrams became apparent. When the two diagrams were traced on the same card there was sometimes a want of symmetry about them, and in this case the cut-off was shorter on the back than on the front diagram. This the author attributed to the friction of the drum when the cord for the back diagram was longer than that for the front. When this was the case the relative lengths of the cord were about 1 to 1·8. These observations were illustrated in a diagram from "Richards' Indicator." To test this diagram, a tracing was taken, and reversed so that the front diagram was superimposed on the back. It was observed that the diagrams were of different lengths, and the difference was about the same as the difference in cut-off; that notwithstanding the apparent cut-off in the back diagram was to that in the front in the ratio of 2 and 3, the expansion line of the back diagram was the same shape as that in the front; and that if the diagrams were restored, supposing the lengths of the cords used to have been 5ft. and 9ft., the diagrams became exactly similar, and, allowing 2 per cent. clearance, the expansion line came to be the true expansion line for that cut-off. The mean pressure was 14 per cent. larger than from the original diagram. Such instances as these seemed to sufficiently establish a case against the blind faith which appeared to be at present placed in the accuracy of the indicator diagrams. But, in conclusion, the author stated that he should be very disappointed if anything in this investigation should have the effect of diminishing reliance on the indicator itself. He would have the instrument treated fairly, and instead of being the object of unthinking worship he would have it the object of careful study and experimental investigation, so that the limits of its wonderful perfection might be known exactly, and that reliance placed on it which sprang from knowledge.

## THE GREENWICH VISITATION.

On Saturday last the members of the Board of Visitors and others assembled at the Royal Observatory, Greenwich, to receive the report of the Astronomer-Royal for the past year. Despite the inclemency of the weather no fewer than 200 gentlemen were present, among them being Professor Huxley, President of the Royal Society; Sir G. Airy, Lord Rayleigh, Mr. E. Dunkin, President of the Royal Astronomical Society, and Colonel Hozier. It appears from the report that the dome for the Lassell reflector has been completed during the year; so, too, has the instrument used during the eclipse of the moon on October 4. It being suspected that some personal equation might exist dependent on the apparent direction of motion of the object observed, a reversion prism has been adapted to the collimators and the transit-circle, so that the apparent movement might be reversed—i.e., instead of the object always passing through the field from right to left it passes from left to right. The observations of the collimators show no evidence of personal equation depending on the direction of measurement, but in order to eliminate any such errors should they exist, half the observations are taken with the direction of movement reversed. A comparison of the observations of transits shows a marked difference between the observations taken in the ordinary manner and with the direction of motion reversed; but as this is only the case for some observers, the Astronomer-Royal thinks it probable that they have not yet become accustomed to the reversion. In order the better to investigate this difference of personal equation the Astronomer-Royal, in concert with Mr. Simms, has arranged an instrument by which various details can be satisfactorily entered into in a manner otherwise impossible. On the publication of Professor Pickering's "Harvard Photometry" all stars which he had noted as brighter than the sixth magnitude and which had not been recently observed at Greenwich were inserted in the working catalogue, in order that the next Greenwich catalogue might contain all stars down to the sixth magnitude which have not been observed at Greenwich since 1860. The annual catalogue for 1884 contains about 1,370 stars, or 166 less than that for 1883. Notwithstanding the gradual increase in the number of observations the reductions are kept in an advanced state. The sidereal standard clock—the real time-keeper of the country—goes very satisfactorily. The public clock at the Observatory entrance and the other mean-time clocks were put forward 12 hours on January 1, so as to show Greenwich civil time, starting at midnight and reckoning from 0h. to 24h., which would correspond with the universal time recommended by the Washington Conference. The change from astronomical to civil reckoning has also been made in all the internal work of the Observatory, and has been carried out without any difficulty. Greenwich civil time is found to be more convenient on the whole for the purposes of this Observatory, but its introduction into the printed astronomical observations has been deferred to allow time for a general agreement among astronomers to be arrived at. It is proposed, however, to adopt the civil day without further delay in the printed magnetical results, thus reverting to the practice previous to 1848, and making the time-reckoning harmonise with that used in the meteorological results, the reckoning from 0h. to 24h. being for the future adopted in both cases.

In regard to the equatoreals, all are, and have been, in perfect working order, with the exception of the Lassell reflector, which has required a number of repairs and alterations, and even now difficulty is experienced from want of stability of the optical axis of the large mirror, which requires continuous readjustment as the telescope is moved. With the various equatoreals, 30 occultations (16 during the lunar eclipse of October 4th) and 57 phenomena of Jupiter's satellites have been observed. Comet (c) 1884 was observed on four nights, and some measures of double stars and of the satellites of Saturn have been made. The observations for determining the rate of approach or recession of stars are considerably in excess of the numbers in former years, no fewer than 641 measures having been made. During the year photographs have been taken on 173 days, the sun's disc being free from spots on only two days. The magnetic registers give evidence of five days of great magnetic disturbance, and 20 days of lesser disturbance, for which tracings of the registers will be published. Pressure of work has retarded the trial of the new photographic apparatus mentioned in the last report; but the apparatus has now been erected provisionally, in order to obtain a series of records to compare with those of the apparatus now in use before the latter is discontinued. The Thames temperature observations are taken regularly at the Deptford Cattle Market, and printed with the Greenwich meteorological observations in the Registrar-General's weekly report. The mean temperature for 1884 was 50·7°—i.e., 1·4 above the average of the last 43 years. The maximum temperature was 94·1° on August 11th; the minimum 24·5° on November 25th. The greatest, mean, and least daily motion of the air were 891, 286, and 78 miles—the first on January 23rd, the last on February 8th. The greatest pressure of the wind on a square foot was 22·7lb. on January 23, there being no other case in which the pressure exceeded 20lb. The rainfall was 18·0in. per square foot—i.e., about 7in. below the average of the last 40 years. The number of hours of bright sunshine recorded by Campbell's instrument was 1,115, or about 100 below the average of the last seven years. In connection with the establishment of hourly time-signals at the Start or Lizard, which was long advocated by Sir G. B. Airy, the Committee of Lloyd's have informed the Astronomer Royal that they would undertake the maintenance of hourly time signals at any of their signal stations provided the Government would supply the necessary apparatus. After consultation with Captain Wharton, it has been thought better that, before taking further steps, some preliminary trials should be made of a collapsible cone as an hourly time-signal, facilities for doing which exist at Devonport. There seems a probability of this long-advocated project being at last carried out. The errors of the Westminster clock have been under 1sec. on 50 per cent. of the days of observation, and over 4sec. on only 4 per cent. The Astronomer Royal points out that there has been an extension in the work of the various departments during the year, and relies on the record of work done as the best testimony to the zealous spirit with which his subordinates have laboured to sustain the credit of the establishment.

The report concludes by pointing out the necessity for a larger telescope; and it is mentioned that over 20 observatories and even persons have larger telescopes than the 12¾in. at Greenwich. For such an instrument as the Astronomer Royal suggests—viz., a 28in.—about £3,500, it is believed, would be required.

## MIND AND MOTION.

The Rede Lecture delivered last week in the Senate House, at Cambridge, by Mr. G. J. Romanes, M.A., F.R.S., was entitled "Mind and Motion." After giving some account of the teaching of Hobbes, who laid it down, on the one hand, that all our knowledge of the external world is but a knowledge of motion, and, on the other, that all our acquisitions of knowledge and other acts of mind imply some kind of "motion, agitation, or alteration, which worketh in the brain," Mr. Romanes pointed out, as regards the internal world, that physiology has proved that molecular movements of nervous matter are concerned in all the processes of reflex action, sensation, perception, instinct, emotion, thought, and volition. The lecturer detailed the discoveries which of late years have been made by physiology concerning the rate at which these movements travel along nerves, the period of molecular vibrations in nerve centres, the time required for processes of thought, and the quantitative relations between brain-action and mind-action. When physiological instruments fail to take cognisance of these relations, we gain much additional insight touching the movements of nervous matter by attending to the thoughts and feelings of our own minds, for these are so many indices of what is going on in our brains. Proceeding to contemplate the mind, considered thus as a physiological instrument of the greatest delicacy, he argued that the association of ideas is but an obverse expression of the fact that when once a wave of molecular disturbance passes through any line of nerve structure, it leaves behind it a change in the structure, such that it is afterwards more easy for a similar wave when started from the same point to pursue the same course. Such being the intimate relation between brain-action and mind-action, it has become the scientifically orthodox teaching that the two stand to one another in the relation of cause to effect. He pointed out that the doctrine of conscious automatism is logically the only possible outcome of the theory that nervous changes are the causes of bodily changes, and, therefore, it cannot be fought on grounds of physiology. If we persist in regarding the relation between brain and thought exclusively from a physiological point of view, we must of necessity be materialists. But it does not follow from this that the theory of materialism is true; and other considerations of an extra-physiological kind conclusively prove that the theory is false. We have, first, the general fact that all our knowledge of motion, and so of matter, is merely a knowledge of the modifications of mind. Therefore, so far as we are concerned, mind is necessarily prior to everything else. Thus the theory of materialism assumes that one thing is produced by another thing, in spite of an obvious demonstration that the alleged effect is necessarily prior to its cause. But further, "motion produceth nothing but motion," says Hebbes, and yet he immediately proceeds to assume that in the case of the brain it produces, not only motion, but mind. Materialism has to meet the unanswerable question—How is it that in the machinery of the brain motion produces this something which is not motion? Science has now definitely proved the correlation of all the forces, and this means that if any kind of motion could produce anything else that is not motion, it would be producing what science would be bound to regard as in the strictest sense of the word a miracle; causation from brain to mind is in the strictest sense of the word a physical impossibility. *Mutatis mutandis* the theory of spiritualism—which supposes causation to proceed from mind to body—is, he held, but little less unphilosophical than the opposite theory of materialism. For just as it follows from the conservation of energy that motion can produce nothing but motion, so it equally follows that motion can be produced by nothing but motion. Is there, then, any third hypothesis in which we may hope to find intellectual rest? If we unite the elements both of spiritualism and of materialism, we obtain a product which satisfies every fact of feeling on the one hand, and of observation on the other. We have only to suppose that the antithesis between mind and motion, subject and object, is itself phenomenal or apparent, not absolute or real; that the seeming quality is relative to our modes of apprehension; and, therefore, that any change taking place in the mind and any corresponding change taking place in the brain are not really two changes, but one change. There is thus supposed to be only one stream of causation in which both motion and mind are simultaneously concerned; motion is supposed to be producing nothing but motion, mind-changes nothing but mind-changes. Both producing both simultaneously, neither could be what it is without the other, because without the other neither could be the cause which in fact it is. The use of mind to animals is thus explained, for intelligent volition is shown to be a true cause of bodily movement, seeing that the cerebration which it involves would not otherwise be possible. This monistic theory thus serves to terminate the otherwise interminable controversy on the freedom of the will; for the theory shows it to be merely a matter of terminology whether we speak of the mind or of the brain as the cause of bodily movement. That particular kind of physical activity which takes place in the brain could not take place without the occurrence of volition, and *vice versâ*. All the requirements alike of the determinist and of the free-will hypotheses are thus satisfied by a synthesis which comprises them both in one. Mr. Romanes afterwards reviewed the opinions of the late Professor Clifford upon this subject, and concluded by observing that if it were true that the voice of science must of necessity speak the language of agnosticism, at least let them see to it that the language was pure; let them not tolerate any barbarisms introduced from the side of aggressive dogma. So would they find that this new grammar of thought did not admit of any constructions radically opposed to more venerable ways of thinking, and that the often-quoted words of its earliest formulator applied with special force to its latest dialects—that if a little knowledge of physiology and a little knowledge of psychology incline men to atheism, a deeper knowledge of both, and still more a deeper thought upon their relations to one another, could only lead men back to some form of religion, which, if it be more vague, will also be more worthy than that of earlier days.

## THE NEW TELESCOPE OF THE PARIS OBSERVATORY FOR STELLAR PHOTOGRAPHY.[*]

THIS new instrument is composed of two telescopes inclosed together in a single metallic tube, in form of a parallelopiped, and separated in their entire length by a thin partition.

One of the object-glasses, 9½in. aperture, and 11ft. 9⅝in. focal length, is used for visual observation, and serves as finder; the other o.g., 13⅜in. aperture, corrected for the actinic focus, is used for the photography: the optical axes of these two telescopes being parallel, the centres of their fields coincide. The instrument is mounted equatorially, and has clockwork movement going for three hours without being rewound, and has very fine independent back movements.

The photo. o.g. is the largest that has been yet made, and is of a simple achromatic system; though it is of a relatively short focus, it can cover with neatness, and without the use of a stop, the large field of 3° diam.

Although the instrument is not yet quite finished, the Messrs. Henry have obtained a proof on the 23rd April last, with an exposure of one hour, representing a surface of the sky of 5° square, and one can count in the photo. 2,790 stars ranging from the 5th mag. to the 14th mag.; those on the edges of the plate being quite as clearly defined as those in the centre of it. Traces of stars of even the 15th mag. may be found on the plate, but too feeble for reproduction on the sensitive paper; they would certainly be obtained by a longer exposure.

The stars of the 14th mag. present themselves on the plate with a diam. of $\frac{1}{20}$ of a millimètre. The construction of such a chart obtained in one hour would, by the ordinary methods, require at least several months of close work.

The following are the necessary *minimum* exposures, but to obtain plates for good paper prints triple the time is required.

It can be seen by this table that the difference of exposure varies between the first and last mag. from 1 to 1,000,000; between two consecutive magnitudes the relation is 2·512.

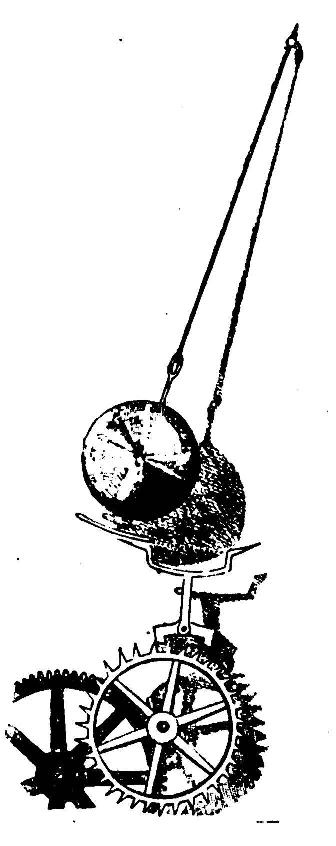
The plates used were the gelatino-bromide of Monckoven, prepared by M. Bernaert of Ghent. The construction of the mechanical portion of the instrument was intrusted to M. Gautier, and the o.g. was made by MM. Paul and Prosper Henry themselves.

---

[*] Translation from Report by MM. PAUL AND PROSPER HENRY, Astronomes-Adjoints de l'Observatoire de Paris.

## HART'S PENDULUM ESCAPEMENT.

A RATHER novel form of pendulum escapement has been recently patented by Mr. Hart, of Kirksville, Missouri, and is shown in the annexed engraving. The improvement claimed consists simply in applying power through a lever escapement to a pendulum. The pendulum, being detached, meets with less resistance after receiving an impulse, and hence is more accurate for time. The power being applied at or below the ball instead of so far above and so near its place of suspension, much less power is required to keep it in motion, or to run the clock. Less power being required, there is, naturally, less wear; and a reduction in springs, weights, and material may be made throughout. Weaker or thinner springs being sufficient, there is less liability of their breaking. The dial of the clock is brought down where it can be easily seen, and no ladder is required in winding. In tower clocks the pendulum may be made of any desired length, and run up into the steeple out of the way. An accurate compensation may be had by extending a rod from the bottom of the ball up, for the support of the pendulum.



# SCIENTIFIC SOCIETIES.

## WESTERN MICROSCOPICAL CLUB.

THE members of the Western Microscopical Club met last week at the house of Dr. Foulerton, F.G.S., 44, Pembridge-villas, Bayswater. The subject for the evening was "A Demonstration in Micro-Photography." The host, who acted as demonstrator, called attention to the great progress which had recently been made in photography, with special reference to the gelatino-bromide dry plates. The essential constituent of these is a bromide of silver, on the molecules of which, themselves no doubt in a continual state of rhythmical movement, certain of the waves of light, synchronous in their action, produce a chemical change, probably the formation of a sub-bromide; but this change, which takes place during the exposure of the plate in the camera, is wholly invisible until acted on by a developer. The composition and action of developers, whether pyrogallic acid with an alkali and a bromide, or the ferrous oxalate, were then dwelt upon. They were oxidisers, which began by attacking the very small amount of sub-bromide produced on the film by the action of light, and resulted in the deposition of silver along with other changes. Whilst this was taking place more bromide was being changed into sub-bromide, with a further deposition of silver, and this was continued until, in the opinion of the operator, a sufficient amount of silver had been deposited to produce a picture in which the lights and shadows were of course reversed, most silver being deposited where the action of the light in the camera had been strongest, corresponding to those parts of the object which were most transparent. After the full effect of the developer had been obtained there still remained on the film a quantity of bromide of silver which had not been acted upon, and which, if allowed to remain, would, on exposure to light, completely destroy the picture, and which had therefore to be removed by hyposulphite of soda, an operation which is called "fixing." The image on the ground glass of the camera of the object on the stage of the microscope produced by the lenses was then dwelt upon. The time required for exposure of the sensitive film according to the degree of enlargement; the distance behind the objective on which the image should be formed; the advantages of artificial light over daylight, and other questions of a practical nature were then alluded to, particularly the best kind of non-actinic light to enable the operator to carry on his manipulations without injury to the most sensitive plates. It was shown that no light which was practically of any use to see by was absolutely non-actinic for any length of time, but that, with reasonable care, a very considerable amount of light, practically harmless, could be got by using a candle surrounded by two or three folds of "Golden Fabric." No light, however, was to be trusted without first testing it, and the method of doing so was pointed out. The lecturer then proceeded to give a practical demonstration of the observations he had made by taking a microphotograph of a rock section with an inch objective (without an eyepiece). A paraffin lamp and condenser were used for illumination. The image was formed at about 2ft. behind the object. An exposure of two minutes was given; development was effected by pyrogallic acid, ammonia, and bromide of potassium, and the image fixed with hyposulphite of soda. The operation lasted about ten minutes, was completely satisfactory, and was watched with much interest by the members present, more particularly the gradual development of the image from a faint beginning till it was fully and clearly out. Then followed its seemingly wanton destruction and obscuration by fog, which is necessary in order to secure sufficient density after the subsequent operation of fixing, in which the image again becomes clear and distinct. The process of obtaining a lantern transparency was then explained and practically demonstrated. Numerous lantern transparencies, both of microscopical objects and of landscapes, were exhibited by the lecturer, with some Dallastype specimens, in which the photos.

are transferred to a block and printed with the letterpress. Mr. J. Harris Leall, F.G.S., and Messrs. How sent a fine collection of photos. of rock sections and crystals for a lantern display. Dr. T. S. Cobbold contributed some photos. of special interest. Some specimens of human liver, kidneys, &c., were sent to him from Alexandria by Dr. Kartulis. These sections were crowded with the eggs of the dreaded fluke, the *Bilharzia hæmatobia*. Very successful photographs of these were prepared by Mr. Charters White, M.R.C.S. Photos. of diatoms, fungi, test-scales, &c., taken by Mr. Herbert Jackson, with powers as high as the twenty-fifth of an inch, elicited much interest. Microscopes were contributed by Dr. H. Snow and Dr. J. Chippendale, the latter exhibiting an interesting section of fœtal lung. Mr. G. Karop showed a beautiful section of the iris of the human eye. Mr. A. W. Stokes, F.C.S. (Public Analyst to Paddington, &c.), was unanimously re-elected hon. secretary, from whom any information as to the new session to commence in October next may be obtained.

ROYAL MICROSCOPICAL SOCIETY.— ERRATA.—In the report of this Society, page 299, last paragraph but one, for "fishplates," read testplates; for "size. of the arc," read sine of the arc; and for "the bottom could be," read the latter could be.

# SCIENTIFIC NEWS.

IN his report for 1884 Admiral Mouchez, Director of the Paris Observatory, refers to the bad situation of that establishment for doing high-class astronomical work, and sketches a scheme for removing the principal instruments to a site where greater steadiness in their mounting can be obtained, and where they will be free from the inconveniences of the present surroundings. M. Bigourdan has carried on his work in connection with double stars, small planets, comets, and nebulæ, determining with greater exactitude the positions of several and discovering no fewer than fifteen new nebulæ. The great Eastern equatorial has been utilised by MM. Henry in observing the satellites of the large planets and the ring of Saturn. M. Loewy and M. Périgaud have been using the equatorial coudé in observing comets and the newer small planets, and M. Obrecht has obtained a number of photometric observations of the satellites of Jupiter with the same instrument. We have previously referred to the photographic star charting of MM. Henry, and an article in another column gives further particulars. The great telescope of 29in. is still unmounted, and the council of the Paris Observatory do not appear to be inclined to accept the suggestion to mount it at the observatory of Algiers—an exceptionally favourable position.

It seems that the dome of the Bischoffsheim observatory, Nice, is the largest thing of the kind. It is a revolving dome, it should be remembered, and is said to weigh nearly 94 tons; but it is easily moved by turning a small wheel, and can be completely revolved in four minutes. As mentioned on p. 275, the dome is to float in a trough rim, and it has, we believe, been determined to try a solution of chloride of magnesium as the liquid, as that does not freeze until the temperature falls many degrees below zero. The telescope will have an object-glass of 30in.

The small planet discovered by M. Borrelly on March 6, No. 246, has been named Asporina.

The conversazione of the Institution of Civil Engineers was held on Friday evening last at the International Inventions Exhibition. The attendants at the stands had an evening's respite, and the public were not admitted after six.

The annual general meeting of the Marine Biological Association will be held to-day, June 12, at five o'clock, in the rooms of the Linnean Society, Burlington House. Prof. Huxley will preside. The sum now subscribed for the Plymouth laboratory amounts to nearly £8,000; of this sum £2,000 was recently contributed to the association by the Fishmongers' Company. The Earl of Derby has recently joined the association and subscribed £100. The Clothworkers' and the Mercers' Companies have contributed handsomely to the association, and it is to be hoped that other companies will follow the example of the Clothworkers, and contribute to this national enterprise.

Prof. Huxley has promised to retain his office as president of the Royal Society at least until St. Andrew's Day, when, owing to the state of his health, he will resign, and indulge in what is called complete rest.

The Swiney Lectures on Geology will be delivered in the Natural History Museum, South Kensington, on Mondays, Wednesdays, and Fridays, at 4 p.m., commencing next Monday, June 15. The course consists of twelve lectures, and Dr. R. H. Traquair, F.R.S., F.G.S., will take for his subject "Birds and Mammals" especially in relation to their fossil forms. Admission to the course is free.

Mr. Nicholas Whitley communicates to the *Journal* of the Royal Institute of Cornwall for May a paper entitled "Traces of a Great Flood in Cornwall," in which he arrives at the conclusion that the flood which deposited the stream-tin in the valley was post-glacial.

Mr. C. V. Boys, demonstrator in the Physical Laboratory at South Kensington, sends us a copy of the syllabus of the course of practical instruction in physics at the Normal School of Science, South Kensington. This syllabus contains clear and concise directions for making a variety of simple apparatus for experiments in physical science. The tools needed are few and inexpensive, and a lathe is not required. The price of the syllabus is 3d. It is sold at South Kensington Museum, and by Chapman and Hall, the agents to the department.

The Council of the Society of Arts have awarded the Albert Medal to Henry Doulton, in recognition of the impulse given by him to the production of artistic pottery in this country.

The coversazione of the Society of Arts will be held at the International Inventions Exhibition, on Friday, July 3rd.

Prof. Verneuil is the President-elect of the French Association for the Advancement of Science for the meeting which will be held this year at Grenoble on the 13th of August.

Mr. F. A. Gower, the inventor of the Gower telephone, is making a series of experiments in aërial navigation or ballooning under the "cognisance" of the Government. He has made Hythe the centre of his operations, whence he recently started a pilot balloon containing about 2,300ft. of gas, with automatic arrangements for giving out ballast and gas. This balloon made a descent near Dieppe, having made a rapid passage of 72 miles in a straight direction. On Monday last week another pilot balloon, with a capacity of 4,300ft., was started, and immediately followed by Mr. Gower in a larger balloon, containing 23,000ft. of gas. His object was to watch the action of the pilot; but the smaller machine made such rapid progress that it got out of his observation and came down in the vicinity of Paris. Meanwhile Mr. Gower, who ascended about noon, made the French coast at Boulogne at 2.15, and then taking a northerly curve travelled overland to Calais, where he made a smooth descent at 4 p.m. On Wednesday Mr. Gower made an ascent with Captain Lane and Mr. Dale; but owing to the wind drifting them to the North Sea they were compelled to descend, and landed in the Isle of Sheppey. Experiments will be made on all favourable opportunities.

Dr. Hickson, who has been studying animal morphology for nearly four years at Oxford, under Prof. Moseley, has started on a voyage of biological exploration in the island of Celebes. His special object is to study the development and life-history of the Alcyonarian corals; but he hopes also to explore the interior of the island, the fauna of which is at present almost entirely unknown.

The Stokes-Watson spark apparatus for showing the combustion of metals under the microscope by the passage of the electric spark through them, made by Messrs. Watson and Sons, of High Holborn, from the design suggested by Professor Stokes, was exhibited by Messrs. Watson at the conversazione of the Royal Society, Burlington House, on the 6th May, and again by them on Friday, the 5th June, at the Royal Institution. It is a most interesting apparatus, the different metals in combustion showing most beautiful colours, and as the apparatus can be added to any ordinary microscope, no doubt it will become very popular.

Senor Ugaz calls attention in the Lima *Cronica Médica* to the vesicating property of the inner bark of the walnut tree. He soaks it in vinegar for fifteen minutes or so, and applies it to the part on which a blister is required. He has found it useful as a remedy for lupus, but he dusted the blister with calomel.

The size of the Atlantic waves has been carefully measured for the Washington Hydrographic Bureau. In height the waves usually average about 30ft., but in rough weather they attain from 40 to 48ft. During storms they are often from 500 to 600ft. long, and last ten or eleven seconds, while the longest yet known measured half a mile, and did not spend itself for 23 seconds.

The Royal Dublin Society have resolved to hold an International Exhibition of Arts and Industries at Ballsbridge in 1887.

An exhibition of domestic gas appliances has been opened at the Parkes Museum, the apparatus being supplied by Mr. Fletcher, of Warrington. The exhibition will be open until the 27th inst., from 10 a.m. to 7 p.m., and on Mondays, Wednesdays, and Saturdays until 9 p.m.

Mr. Walker (Walker, Parker, and Co., Bagillt) having read the lecture on "Dust" delivered by Prof. Oliver J. Lodge at the Montreal meeting of the British Association, was struck with the results of the experimental passage of electric sparks through dust and smoke-laden atmospheres, and conceived the idea of applying the principle to the condensation of lead "fume" at the smelting works. Experimental trials gave results so satisfactory, that two large Wimshurst machines, with discs 5ft. in diameter, are to be employed for dealing with the "fume" at the Bagillt works.

A memorial statue of Charles Darwin, designed by Mr. Boehm, R.A., was unveiled on the 9th inst. by Prof. Huxley, in the great hall of the Natural History Museum, in the presence of the Prince of Wales and a large assembly, including many of the most prominent scientific men of the day. The Prince of Wales received the statue on behalf of the trustees of the Museum.

# USEFUL AND SCIENTIFIC NOTES.

**New Expanding Mandrel.**—Messrs. H. B. Barlow and Co., of Manchester, have introduced a new mandrel, in which they have worked out several improvements upon the Harrison expanding mandrel manufactured by this firm for some years past. In the new mandrel, pulleys or heavy wheels can be turned upon it without any back centring, and one great advantage is that it brings the work very much closer up to the face-place than in the old mandrel. The body of the mandrel consists of a steel forging, flanged with a taper nose, bored up, in which a bolt works. The split dies, which are bevelled at each end, work upon the taper nose, and the mandrel is expanded by simply turning an ordinary hexagon-headed bolt and released by turning this bolt in the opposite direction.

THE Great Northern Railway are lighting one of their trains with E.P.S. accumulators, placed in each coach. The cells are charged by a dynamo driven from the axles, and an E.P.S. magnetic switch closes the circuit when the electro-motive force of dynamo rises above that of the cells. The Electrical Power Storage Company have lately supplied accumulators for use on the Lancashire and Yorkshire Railway, as well as the Great Eastern Railway.

FIRST-CLASS carriages are not much required on some German lines. The statistics have always shown that they are little used. On one of the State Railway systems in the year to March 31st, 1883, only three passengers in a thousand travelled first-class, so that most of the trains must have no first-class passengers at all.

THE *Allgemeine Brauer-und-Hopfen Zeitung* gives the following as being the most recent statistics with regard to the tax upon spirits in Europe:—The tax yields a revenue of £18,725,850 in Russia, of £15,581,290 in Great Britain, of £14,508,000 in the United States, of £10,603,660 in France, of £2,334,640 in North Germany, of £1,890,450 in Holland, of £1,062,400 in Austria-Hungary, and of £681,200 in Belgium. This is equivalent to 9s. per head of the population in Holland, 8s. 6d. in Great Britain, 6s. in the United States, 5s. 6d. in France, 4s. 6d. in Russia, 2s. 4d. in Belgium, 1s. 3d. in North Germany, and 7d. in Austria-Hungary; while the consumption per head of alcohol is given as 2½ gallons in Denmark, 2 gallons in North Germany, 1½ gallon in Russia, rather less than 1½ gallon in Austria-Hungary, 1¼ gallon in Belgium, 1⅛ gallon in France and Holland, 1 gallon in Sweden, two-thirds of a gallon in Great Britain, and rather less than two-thirds of a gallon in the United States.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. Passmore Edwards.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

## THE SUSPECTED VARIABLE STARS HEIS 121 PERSEI—π′ ORIONIS—B. 147 MONOCEROTIS — 60 LEONIS — SOME FINE RED STARS—TWO PROBABLY VARIABLE STARS.

[24339.]—Heis 121 Persei.—This star is No. 106 in Gore's Catalogue of Suspected Variable Stars, and in the Harvard Photometric *Observations*, No. 729. The star has been suspected of variation, from the fact that Peirce found its magnitude 5·8, and Heis 6·0, while the D. M. makes it 7·7. There is a most important note in the second part of Vol. XIV. Harvard College *Observations* on this star. It would seem that both Heis and Peirce really observed D. M. 49° 1155, which is a bright 6·0.

π′ Orionis.—The following note appears in the same vol. of Harvard College *Observations*: "W. H. Gage thinks the period is 28 ± days," and the reference *Observatory* VII. 132. I have not been able to verify the reference, but it is probably an account of the seventh meeting of the session 1883—84 of the Liverpool Astronomical Society. Mr. Gage then stated that "observation could alone determine whether 28 days, or a semi-period of 26·5, is the better of the two." He there finally deduces—

P. 54·73 weighted.
Mean period 54·50.

The star is undoubtedly variable, but the observations are perplexing. Probably the comparison stars are variable. Mr. W. E. Jackson, of Constantinople—a most careful observer—has furnished me with the following observations. Comparison star $\pi^3$ = 3·90.

| Date. | h. m. | $\pi^1$ | $\pi^5$ |
|---|---|---|---|
| 1884. Nov. 25, | 9 20 | 3·57 | 4·04 |
| 26, | 7 37 | 3·71 | 4·03 |
| 28, | 7 30 | 3·83 | 4·12 |
| 29, | 9 20 | 3·90 | 4·19 |
| Dec. 7, | 6 15 | 3·60 | 4·20 |
| 7, | 7 40 | 3·82 | 4·0 |
| 8, | 7 35 | 3·64 | 3·78 |
| | 9 5 | 3·57 | 3·79 |
| 9, | 7 44 | 3·45 | 3·79 |
| | 8 33 | 3 69 | 3·76 |
| 10, | 4 12 | 3·84 | 4·04 |
| 11, | 6 20 | 3·63 | 3·81 |
| | 9 0 | 3·64 | 3·80 |
| 12, | 6 28 | 3·76 | 3·90 |
| | 9 14 | 3·79 | 3·90 |
| 14, | 5 55 | 3 90 | 3·90 |
| | 8 5 | 3·89 | 3 89 |
| 15, | 7 19 | 3·41 | 3·90 |
| | 8 3 | 3.79 | 3·90 |
| 16, | 8 23 | 3 56 | 3·90 |
| 17, | 5 53 | 3·63 | 4·14 |
| | 7 58 | 3·63 | 3·90 |
| 23, | 9 33 | 3·57 | 3·90 |
| 27, | 10 3 | 3·8 | 3 80 |
| 1885. Jan. 5, | 7 54 | 3·74 | 3·90 |
| | 9 58 | 4·01 | 3 99 |
| 6, | 8 49 | 3·76 | 3·86 |
| 12, | 7 47 | 3·63 | 3 96 |
| | 9 51 | 3·63 | 4·01 |
| 15, | 8 58 | 3·75 | 4·05 |
| 16, | 6 16 | 3·62 | 3·81 |
| Feb. 18, | 8 54 | 3·66 | |
| 20, | 7 9 | 3·70 | |
| | 8 31 | 3·64 | |
| 21, | 7 54 | 3·85 | |
| March 8, | 7 49 | 3·81 | |
| 9, | 6 44 | 3·90 | |
| 10, | 6 39 | 3 60 | |

The observations range
From 3·76 to 4·20 for $\pi^5$ and
From 3 41 to 4·01 for $\pi^1$,
or for $\pi^5$ they vary 0·44 and for $\pi^1$ 0 60.

B. 147 Monocerotis—Gore 186.—Pickering points out that Birmingham has confused this star with a bright star H. P. 1189. The difference between the two in R. A. is 10 minutes, which seems unaccountable. On Feb. 27, 1855, while reobserving Birmingham's objects, I found B. 147, 6½ reddish, and discovered another red star, ± 1m. 26s. *f.* and 7′ ± south, of the same colour. The magnitude of this star was 8½. The following observations of B. 147 were made at the Dunsink Observatory:—

| | | | | |
|---|---|---|---|---|
| 1876. | Feb. | 5 | 6·5 | deep yellow |
| | | 19 | 7·0 | deep yellow |
| 1879. | Jan. | 3 | 7·2 | orange |
| | | 16 | 7·5 | orange |

60 Leonis.—This star has not, as far as I am aware, ever been suspected of variation. It must, however, be variable in colour, unless the observation of Schmidt, mentioned by Birmingham, be really of some other star. The reference is *Astr. Nach.* 1902, and the colour red. Franks found it greenish. During the re-observation of Birmingham's red stars with the 9in. equatorial reflector I found it yellowish white 1885, March 6, and pure white May 7. It seems probable that there must be a mistake somewhere. It is a little curious that 61 Leonis is a fine orange star. The places of the two stars as taken from the Havard Photometry are

61 10 55·7 − 1·50
60 10 55·9 + 20·49.

But it seems almost impossible that so great an error as 21° could have been made.

Since February last more than 100 of Birmingham's red stars have been reobserved. It may be well to give the finest of those observed up to the present time.

h. m. s.
B. 135 6 3 26 + 26·2 1885, Feb. 5, 8·0, very fine red.
B. 148 6 28 18 + 38·32 1885, Feb. 5, Feb. 9, Feb. 20, very fine red, 6·0 mag.
B. 165 7 1 7 − 7·22 1885, Feb. 27, 8½, remarkably fine red.
B. 166 7 2 27 − 11·44 1885, Feb. 27, 8·0, very fine red.
B. 209 8 46 30 + 19 46 1885, Feb. 17, 9·0, remarkably fine red.
B. 248 10 45 47 − 20·36 1885, March 6, 7½, blood red, certainly the finest I have seen.
B. 250 10 54 39 − 17·40 1885, March 6, crimson, but not deep.
B. 277 12 19 7 + 1·26 1885, March 6, magnificent red, 8·7, May 12, 8·8, magnificent red.
B. 328 14 18 47 + 26·15 1885, May 1, 8½, very fine red; mag. 12, 8·3, very fine red.
B. 448 18 28 9 + 36·50 1885, May 1, crimson, very fine, 8·0; May 12, magnificent red.
B. 458 18 38 40 + 36·50 1885, May 1, crimson, 8 0; mag. 12, fine red.

The star B. 448 is one of the finest in the heavens. It can be easily found by sweeping 22 minutes preceding δ Lyræ, and 10′ to the north. To see it to perfection it should be observed on a perfectly dark night.

Probably the star B. 431 is variable. Its place is 18h. 7m. 50 + 22 48. This star, which is 7·5 in the D. M., was observed by Birmingham as 8·0, pale red, Oct. 12, 1876. It was swept up independently last night, June 2, with the 9in., and was noted 6½ mag. reddish.

Search was made last night for the red star B. 437, 18 16 33 + 25·0. This star was observed by Secchi as "bellisima stella, rossa." It was not observed by Birmingham. It is identified with LL 33896, mag. 6·5, Bessel 435, 8 mag.

No red star was found in the place by me. The star D.M. 24·3395°, which Birmingham believes to be the same as Secchi's star, was observed as 7½, and white. The following are the Dunsink observations:—1875, Aug. 3, 8·0, yellowish white. 1879, June 19, 7·7, no colour. 1880, June 14, 7 5, no colour.

The date of Secchi's observation is July 16, 1868, and the description "most beautiful red star 7 mag. with columnar spectrum." Birmingham points out that the place, according to Secchi, would be for 1880.

18 15 5 + 25·2° ±.

This seems to suggest that the star LL 33896 is not identical with Secchi's star. If Secchi's place be correct, the star must have disappeared.

**T. E. Espin.**

Liverpool Astronomical Society's Observatory, West Kirby, June 2.

## PARTIALLY GRAPHIC METHOD OF COMPUTING OCCULTATIONS OF STARS BY THE MOON.

[24340.]—The mode of computation which I have recently advocated in your columns is capable of being facilitated by one or two abbrevations to which I should be glad to call the attention of amateurs. They have been suggested to me by Mr. Charles L. Woodside, of Boston, U.S.A.

And, first, the American nautical ephemeris confers a benefit on amateurs who will use the partially-graphic method, by inserting in the "elements of occultations," which correspond to those which occupy from pp. 402—434 in the *Nautical Almanac*, a column which shows the *Greenwich hour angle at the mean time of conjunction in R.A. of the moon and star.* This enables us to exhibit in *three* lines of figures what otherwise requires eight—i.e., when the *Nautical Almanac* alone is available.

Secondly, tables are being constructed and about to be published, wherein the values of $\frac{100}{P \rho \cos. l}$ and $P \rho \sin. l$ are shown for all values of the moon's parallax, and each semi-degree of *geocentric* latitude. These will reduce almost to a minimum the mathematical part of the process.

Thirdly, by inserting the local meantime of conjunction in the diagram at the point where the meridian crosses the centre of ellipse of projection of the star's declination, and then ranging the intervals of hours and minutes along the ellipse, and the moon's path as before, the times of beginning and ending are exhibited at once. This, however, seems to possess less advantage in point of accuracy than the plan I first suggested.

**James Pearson, M.A., F.R.A.S.**

Fleetwood, June 5.

## THE ORIGIN OF COMETS.

[24341.]—I quite agree with the substance of the remarks made in your columns by "W. C. E." and Mr. Denning (letters 24274 and 24313 respectively) upon the origin of comets. In the ordinary way, no doubt, the particles of any mass, however closely packed, would, for reasons stated by these two gentlemen, eventually resolve themselves into an elliptic ring encircling the sun. But, nevertheless, although this statement may be generally true, although it is probable—nay, certain, that an ellipse of particles would be ultimately assumed, a ring, such as some of the meteoric rings with which we are acquainted, could not be formed. This was my meaning when I stated before the Liverpool Astronomical Society that a ring could not be formed by planetary eruption. I did not mean to infer that a *ring-shaped* formation could not be generated, but simply that a ring like the November meteor-system is, to all intents and purposes, an impossibility.

In the first place, it is to be observed (granting, for the present, the hypothesis of planetary eruption) that the original mass would have to be ejected from the parent planet on the instant. Allow only an hour to pass while a mass sufficiently large is being cast forth, and we find that not only has the planet advanced some thousands of miles along its orbit, but its rotation will have carried the point of eruption perhaps some 30° or 40° from its former position with respect to its own centre. Now, how in this case could a ring result? I look upon it as impossible that a quantity of matter sufficient to form, say, the November meteor-system could have been ejected in one hour only; but I also look upon it as impossible that it could have taken anything like that time; for, given an hour as the time occupied, it is clear that instead of a ring, properly so-called, the particles would spread out here in perihelion to something more nearly resembling a portion of a disc.

But even if we strain a point for the sake of making the case as favourable as possible for the eruption theory, and assume that the mass *was* cast forth instantly, how far have we advanced? One thing is certain, and that is that the particles on the side nearest the sun would get round him first. Hence the influence necessary for the formation of a regularly-shaped ring structure is assured; but there are certain perturbations to be considered, and everyone of these would assuredly make a difference in perihelion distance. Whether the particles were retarded or accelerated they would diverge from their paths and spread out over the plane of the ecliptic; and this effect, in the case of the November meteors, would have its maximum result just at the point where we are best situated for observing it —viz., where it crosses the earth's orbit. And I fancy that before the mass could lengthen out to some 3,000,000,000 of miles and more the breadth would cover a rather wider space than it now covers. There is also a further difficulty (which, however, I cannot pause to discuss, as it is rather complex), that a body cast forth from any of the planets will combine its own velocity with that of the generating body.

On the other hand, none of these difficulties appear in the views I have been led to maintain. We have, according to my views, a mass of particles, or nebulous matter, drawn into the sun's domain by his attraction; therefore, granting the mass to be sufficiently large, it will so lengthen out as it nears the sun that it may have a length of millions of miles, and in this case we should have a much more conveniently-shaped mass than before upon which to apply the considerations so ably brought forward by "W. C. E." and Mr. Denning. All that is required is that the chaotic matter near the sun should have been much more dense in former ages than at present, and I take it that this is a matter which admits of no question. The considerations upon which I take my stand are these: In the early ages of the solar system the sun must have been surrounded by a dense nebulous envelope, extending outwards, perhaps, for millions of miles. Any body, therefore, travelling towards him would experience some resistance in consequence, and if this resistance were sufficient to transform its orbit from a parabola, or hyperbola, into a closed curve, the captured body would belong to the sun's family thenceforward for ever.

I think I can claim for my theory that, besides being of greater simplicity, it enables us to look upon the comets as relations, and not as vagabonds; their present subordinate position being due to the circumstance that the planets are older, and must have already been possessed of some considerable influence in the solar system when the comets were captured.

With regard to "W. C. E.'s" opinion that we cannot absolutely negative the eruption theory, I can only say that there are many things astronomical which I should not care to try to negative, but of whose absurdity astronomers are pretty well assured. The grand old theory, for example, that the moon is made of green cheese is absolutely unassailable by direct proof; nevertheless, I do not suppose that most people would have much difficulty in making out that the probabilities are the other way. If we cannot meet the eruption theory with a direct negative, it is quite and equally certain that Mr. Proctor cannot support it with a direct affirmative. The question is solely one of probability, as, indeed, are most scientific theories; and I consider my own ideas on the origin of comets as slightly more natural than those of Mr. Proctor, albeit I hold them so lightly that I am prepared to cast them aside directly their insufficiency is shown.

Nor can I quite accept Mr. Denning's opinion that we ought to collect more material before we attempt to theorise. It seems to me that theory and observation ought to go together, for both must receive an impetus by the companionship. Wherever they have gone together hitherto the results have been of the best, and I am sure that Mr. Denning will agree with me when I say that of all the greatest theories yet made the principal evidence came after those theories were propounded; as, for instance, in the systems of Copernicus, Newton, and Herschel. I opine that if the last-named astronomer had waited for more materials before commencing to put together what he had we should know very little more about the structure of the sidereal system now than people knew then.

**J. R. Sutton.**

## ASTRONOMICAL.

[24342.]—In my last letter (No. 24224) of the "E. M.," line 9, for "diminished," read "increase"; line 11 from bottom, for "130°," read "103°."

I feel much indebted to Mr. Sadler for giving correct measures of positions and distances in his letter 24270. His surprise at my not seeing some comparatively easy *comites* while I could see others far more difficult, was no less a puzzle for me after having read his letter.

Looking over the whole matter, I came to the conclusion that there must be some defect in the adjustment of the mirrors. To make sure of it, I dismounted the telescope, placed the mirrors in again, and adjusted by daylight. At night I perfected the adjustment on Arcturus, using a power of 550, until the expanded disc was reduced regularly to an intensely brilliant spot. I then focussed it exactly on a 6th-mag. star. I must say here, that I have long ago given up the rack-focussing system, and replaced it by a fine movement, analogous to the one given to the best class of microscopes. I can, therefore, focus my telescope with great exactness. I then looked at 25 Can. Ven., and at once I saw the *comes* under the ring, and recorded its position-angle about 150°. I then turned on 42 Com. Ber., but there was no longer that slight elongation towards 140° I had seen so often during this season. It was, therefore, evident that a flare had deceived me, and covered the *comes* of 25 Can. Ven. I promised myself to watch more carefully over the adjustment of the mirrors, especially as my telescope must be taken in and out at every observation. The liability of getting easily out of order is the only complaint I can make against my telescope. If a permanent adjustment could be obtained for reflectors it would be a great boon. The measures of B 1880 appended to 64 Pegasi, belong to 72 Pegasi. For 64, read "Just seen at intervals." In an observation of May 9, 1884, of B. A. C. 3992, I see inserted the measures of B, which show that I must have seen the *comes* about that place; otherwise I would have recorded my own at position, according to my habit of doing so. Would Mr. Sadler kindly look over the following stars?—May 27, 1875, Gled. 430, P = 260° ±, wide with 600. There seems to be a greater difference between the mag. of the components, xiih. 58m. + 21° 50′, P = 230°; 0·3″ at 7, 8, ashy, suspected double, $\gamma$ Coro. Bor., P = 140° ±, power 735, and also with power 370. In looking over my previous observations I read the following under the date of June 28, 1882:—"I feel almost certain of an elongation of $\gamma$ Cor. between 110° and 120°." Can any one say whether the *comes* was near that place at that time, and its distance? May 28, B 612. This is the N. of two stars in finder. There seems to be a very slight elongation about 15°. Power 550. B. gives 54·4°; 0·19″; 6·6, 1878·438, and calls it very difficult. I know such stars are theoretically far beyond my means, still I find them a very good exercise for training the eye. B 619, seen at once, 350° ±. It is very close $\mu^2$ Boötis, 115° ± easy, May 30, Gled. 465, 30° ±. It is excessively close. De. 0·34″, Gled. 466, with power 370, an elongation towards 25° ±; but it is excessively close, closer than preceding one, De. oblong, not observed since 1865·33. Gled. 467, 260° ± $\xi$ Boötis, 275 ± Gled. 469, 310° ± 0·64″, Gled. 470, 205° ± easy. May 30, Gled. 494, AB, 170° ±. Very close. Elongation very slight. Power 550.

I tender also my thanks to Mr. K. T. Tarrant for giving the calculated position of 42 Com. Ber. If it is not too much trouble, may I ask him what are the elements of that star for this year, and the way he obtains his results?

**C. M. G.**

## INTRODUCTORY — ANOTHER HOME-MADE TELESCOPE—GRINDING AND POLISHING FLATS — SILVERING SPECULA—GLASS DISCS—AUSTRALIAN SCIENTIFIC AND MECHANICAL ASSOCIATION.

[24343.]—Having been a subscriber to "Ours" since 1876, and having largely profited by the information on various subjects interesting to me, so generously given by your many correspondents, I think it is only right that I should join their number, if only to thank those who have thus given valuable assistance, each in his own special subject, so fully and so freely to all. Large as is the circulation of the English Mechanic (as evidenced by the many and distant places from which its contributors write), it well deserves to be even larger still, for the benefits conferred on and derived by its numerous readers grow in a still larger ratio than even the increase in its circulation. It supplies a want in the scientific and mechanical world that no other paper could meet so well. And first, let me specially thank Mr. Wassell for his valuable and exhaustive series of articles (still in progress) on "Grinding and Polishing Glass Specula." If those articles prove of the same service to others as they have to me, great will be the increase in the number of first-class specula, and I hope of first-class amateur astronomers too. Mr. Wassell's method of figuring and testing is certain in its results, and his explanation of that method, as detailed in your pages, is beyond all praise. I began by building his machine strictly according to his plan (except that I made it to fit on the bed of my lathe, and drove it by a cord from a pulley on the crank shaft, thereby making easy the driving of the machine, and leaving both hands free). I made the grinding tool and testing aparatus exactly as described by him, and by carefully following his instructions (so far as they were then published), I succeeded in making a thoroughly good 6½in. mirror—without rings—good to the edge, and sharp and clear in definition. True, I have expended exactly 150 hours in grinding and polishing the face of that mirror (apart from the various subsidiary processes), but much of this time was spent in gaining experience and acquiring that manual dexterity which would now be instinctive; and, besides, I would not be satisfied with the figure until it was fairly correct according to Mr. Wassell's method of testing and measuring at the centre of curvature. I have mounted it on a simple equatorial stand, and so far (as tried on the moon and Jupiter) the result is very gratifying; but the weather has not been good enough for critical testing. Mr. Brashear's letters, too, were of great assistance. My second attempt at grinding flats was fairly successful, as judged by the colour test. I did not, however, adopt the method of grinding described by Mr. B. I made no tools, but took three glass discs of best French plate, and ground one against the other (judgmatically, of course) with 30-minute emery, until the inequalities disappeared; then took a fourth disc, the same size; covered it with hard pitch, grooved it, and flattened it alternately with two of the ground discs. The third—that is, the one for the time being about to be polished—must not be used to figure the pitch on which it is to be worked. As the polishing proceeds the discs may be tested in regular order, one against the other, and the error in figure judged by the colour test, and corrected accordingly. I believe that by this method good work may be produced, and it is very convenient for the amateur. I used Mr. Brashear's method of silvering, as given in No. 794; result, a bright film, but will not adhere firmly to the glass. When the reserve silver is added, I fail to get the "clear yellowish brown liquid." The addition of the reserve silver causes the liquid to become turbid, and if still more be added (as directed) a thick flocculent precipitate is formed. The deposit in this case will be a greyish mud instead of silver, so I stop adding silver when the precipitate begins to form, with the result first mentioned. Will Mr. Brashear kindly advise?

I am so pleased with the 6½in. speculum that I intend to make a larger one so soon as I can get the glass, which will have to be ordered from England. Will any correspondent oblige by saying where glass discs, varying in size from 6in. up to 12in., may be obtained, and at what price one or more of each size can be packed and delivered by, say, "Orient Parcels Post?" I know that the reply to this may be called an "answer to advertisements"; but in support of my request, I would point, for instance, to Mr. Haren's letter (23812). He there tells us where, and at what price, diffraction gratings may be obtained—very valuable information to the amateur astronomer—and of which I shall gladly avail myself so soon as I can successfully finish a mirror worthy of such an adjunct. Similarly, the information above sought for would be very useful to many on this side of the world besides myself.

And now I would ask leave to address more especially my fellow readers of "Ours" in these Colonies. I am very anxious to see established an Australian Scientific and Mechanical Association, to be composed of all Australian readers, who are engaged in the study and practice of the sciences and arts treated of in these pages. In this city alone, containing over a quarter of a million of inhabitants (not to speak of any other), there must be at least the nucleus of such a society, which, when formed, might in many ways be made of great advantage to its individual members, and I would be very glad to meet with, or hear from, any one willing to assist in its formation. There are many subjects on which I would like to write, but my letter is growing too long.

I will only now add that if there be any information which I can give, or attain for your readers, I will do so willingly, if they communicate their wishes through our pages.

**Robert W. Wigmore.**

36, Collins-street West, Melbourne, Victoria.

## EYEPIECES.

[24344.]—I see on page 300 a statement that in the Galilean telescope "the only effect of that eyepiece is to render them more nearly parallel; or, perhaps, it would be more rigidly correct to say, less convergent."

I don't object to the statement taken in conjunction with the context, which is written for a purpose, and, perhaps, shows that more clearly as it stands; but for the sake of beginners who might be misled, I want to state that the function of every eyepiece, or combination of lenses next the eyes, is to render the rays *divergent* when they strike the eye—divergent from a point, say, 5in. to 15in. from that eye—and that, no matter what telescope, microscope, or simple magnifier we use, this *must* be the final state of things.

In the Galilean eyepiece the concave not only renders the rays "less convergent," but so much less that the convergence left is negative—that is divergence. In the ordinary astro-eyepiece or magnifying glass the lens, lessens not convergence but divergence, till it reaches the proper amount.

So few works on optics draw decent diagrams for beginners, that, perhaps, the above may help them; or, if you think worth while, I will draw out a few clearly for the commoner instruments with sufficient letterpress to explain the examples.

**Bow.**

## GEOCENTRIC CO-ORDINATES OF A PLACE, AND PEARSON'S PARTIALLY GRAPHIC METHOD OF COMPUTING OCCULTATIONS AND ECLIPSES.—THE NEW TIME.

[24345.]—In all calculations involving the geocentric co-ordinates of a place, it is a matter of considerable embarrassment to amateurs to find them, unless supplied with tables for that purpose, which are generally published only in costly works, and, therefore, not, perhaps, within the reach of all.

Believing Mr. Pearson's partially graphic method to be practical, accurate, and expeditious, and easily understood by any person of ordinary intelligence, I think all my brother amateurs should avail themselves of its use, and in order that those not having tables may not be prevented from adopting it. I have calculated a table by which the co-ordinates $\rho$ cos. $l$ and $\rho$ sin. $l$ may be easily found. A single example will suffice to show its application:—To find the co-ordinates for Boston, Mass., geographical latitude, 42° 21′ 28″ North—

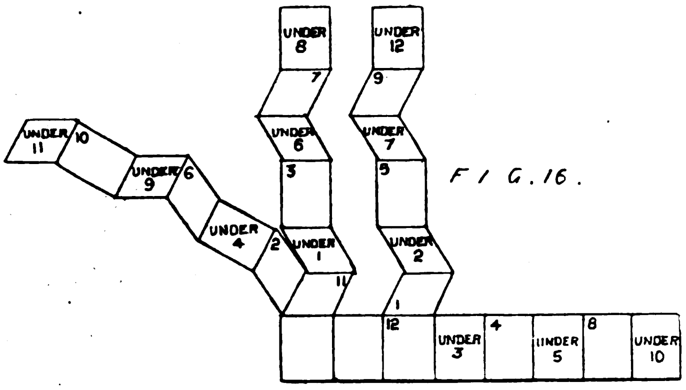
Log. cosine .................... = 9·86861
Log. A .......................... = 0·00066

$\rho$ cos. $l$ ...................... = 9·86927

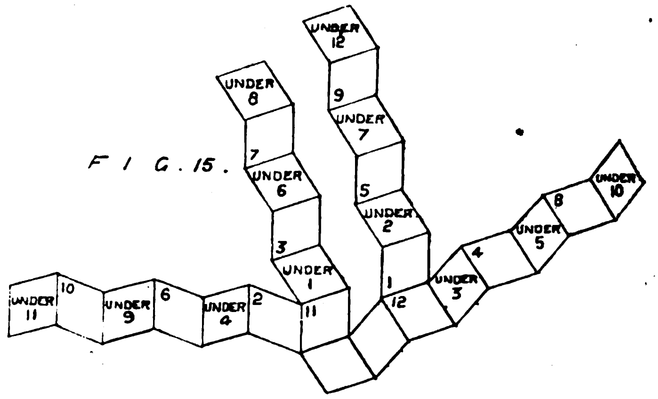
Log. sine ...................... = 9·82851
Log. B .......................... = 0·00225

$\rho$ sin. $l$ ....................... = 9·82626

This is an old method, but it may be new to



F I G. 16.



F I G. 15.

many, and the table will certainly be useful to all. It is calculated for every degree of geographical latitude, the figures carried out five places only, as that will insure all needed accuracy.

Table for Computing the Geocentric Coordinates of a Place.

| Geographical Latitude. | Log. A. Add to cosine. | Log. B. Deduct from sine. | Geographical Latitude. | Log. A. Add to cosine. | Log. B. Deduct from sine. |

We have had miserable observing weather here lately, with only an occasional fine night, during which, however, I have had some excellent views of Jupiter and a little time for comet-seeking.

In regard to striking the hours of the new time, why not strike *one* at the first, seventh, thirteenth, and nineteenth hours, *two* at the second, eighth, fourteenth, and twentieth hours, &c., up to six? I have fixed a clock to strike that way with the most satisfactory results. It is easily understood, and one is not at all likely to mistake the proper hour. **Chas. L. Woodside.**

Boston, Mass., May 26.

## A NEW METHOD OF FORMING CRYSTAL MODELS BY PLAITING.

[24346.] — Finding I am trespassing too much on your valuable space, I inclose, as my last letter on this subject, the analytical table of plaits requiring four fillets and two illustrations—Fig. 15, the rhombic dodecahedrom; and Fig. 16, the hexagonal prism.

It will be seen from the table that there are a variety of hexagonal prisms; each of them, however, is different from the rest. I should have liked, had space permitted, to say a little about this table, for I fear that its meaning is not very self-evident. However, perhaps some readers of the "E. M." may make it out, and if so, I hope this subject will interest them. I shall be willing at any time to give further help if it is wanted.

Analytical Table.

| | |
|---|---|
| Cube Composite, each face containing four isosceles triangles of 90°. | Cube. |
| Angles reduced from 90° to 83° 37′ 14″.................. | Tetrakis hexahedron. |
| Isosceles triangles of two kinds, 90° and 70°, united.......... | Right sq. prism, with 4-sided pyramids. |
| Isosceles triangles reduced from 90° to 70° 31′ 44″............. | Rhombic dodecahedron. |
| Rhombic Dodecahedron, lateral planes elongated. | |
| Angles of rhombs reduced from 109° 28′ 16″ to 99° 2′ 12″ .... | Hexagonal prism, with 3-sided, pyramids. |
| Lateral planes becoming 58° 24′ | Hexagonal prism (diaptose). |
| Angles of rhombs enlarged to 120°, lateral planes rect. .... | Hexagonal prism. |
| Each rhomb replaced by 2 isos. triangles .................... | Hexagonal Prism. |
| Lateral planes not elongaged, rhombs creased in long diagonals. | |
| Angles 60° and 120° .......... | Octohedron. |
| Angles 61° 55′ 50″ ............ | Triakis Octohedron. |
| Rhombs replaced by pentagons ........................ | Pentagon dodecahedron. |
| Rhombs resolved into 4 rect. triangles .................... | Composite rhombohedron. |

Park House, Tonbridge. **E. A. Tindall.**

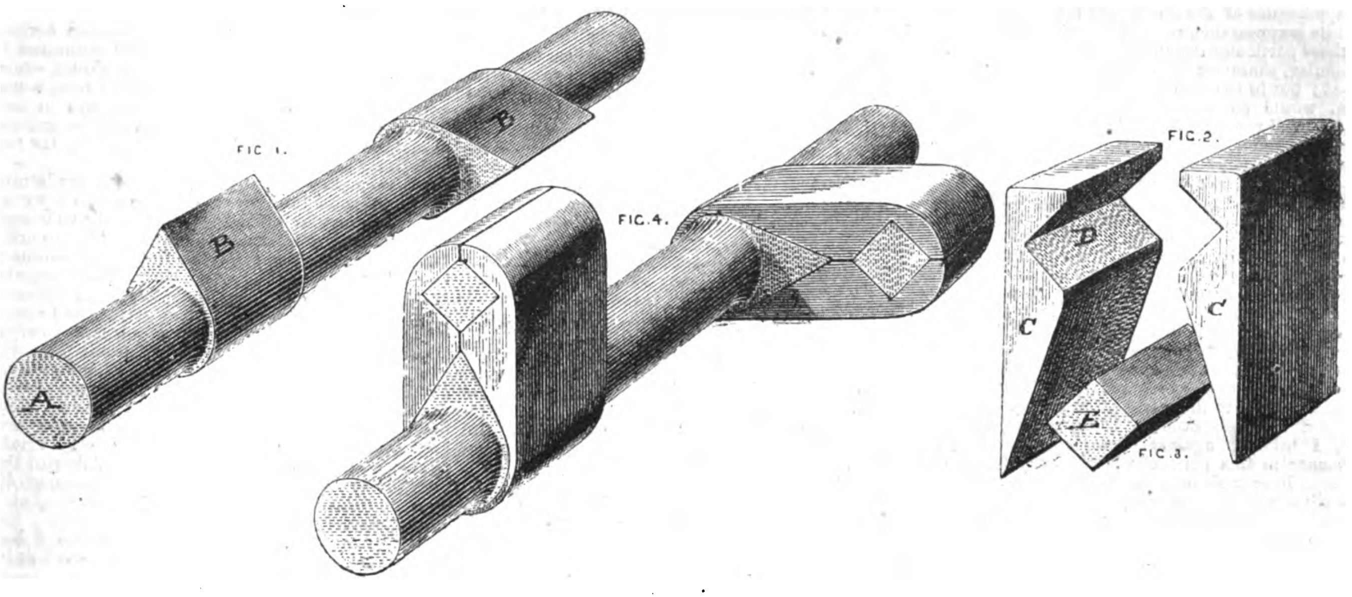
## MOUNTING BACTERIA—COMMA BACILLI.

[24347.]—I trust I shall have no difficulty in setting myself right with so kind a critic as "Medicinæ Doctor," who, after all, seems to believe that consumption is infective. I must acknowledge that I had in my mind not the feelings of the sick or of those who attend them, but the mere and simple position of the person who sits down to mount "bacteria." Such a person has no right to incur the slightest danger, either to himself or to others; he cannot tell whether he is "either owing to a temporary lowering of the system from other causes, or from a constitutional or hereditary tendency, liable to contract tuberculosis." Therefore, he is, I think, in duty bound to take all the care he reasonably can; and the little precautions I mentioned are easy in themselves, and become habitual and instinctive. I believe it is well they should do so; because then, if anything dangerous should come to the fore, and this is very likely to happen, even if only for the reason that a person who tries one kind of bacteria is likely to try another, they stand in the breach, and tend to prevent possibly calamitous consequences. At the same time, I desire clearly to say that I had no intention of conveying any impression that consumption is infectious in the same sense as typhus or measles; but I was keeping to my point, and speaking in the interest simply of the "bacterium" mounter. As to diphtheria sputum and the like, I frankly admit myself to be so cowardly that I would not do it without a solid reason; and if I did it, I would apply bichloride of mercury, wear a respirator with carbolic acid, or both. I may be unreasonable; but, like the navvy in the song, "I valleys my life." Besides, one has others to consider. As to stains, I have not my previous letter before me; but my impression is, that I mentioned not aniline green as the second stain in Heneage Gibbes's method—if I did so it was a slip of the pen—but a saturated watery solution of methylene blue. Heneage Gibbes ("Practical Histology and Pathology," pp. 141-2) says: "Make a saturated solution of methylene blue, methyl green, or iodine green (*i.e.*, iodine aniline green) in water. . . . The above-mentioned stains are the best for diagnostic work; but a watery solution of chrysoidin is the best when the structure of the bacillus has to be studied." Chrysolin, I have little doubt, is chrysoidin under another name. I got some "chrysoidin" from Hopkins and Williams, who supply Heneage Gibbes with his stains, and made a saturated solution with distilled water; but, like "Medicinæ Doctor," I found that it did not work well, the fault being that the stain was too faint. Nor did the iodine green and the methyl green (though beautiful stains for many purposes) work at all well, while the methylene blue has always done so admirably in my hands, producing preparations quite equal to the German ones or to those by Dr. Wallis, all of which are apparently dyed with this stain. It is true that the details of the bacilli do not come out so well when they are on a blue ground; but I think this is because of the intensity of the blue, which shines through, and not because of the blue in any way spoiling the coloration of the bacilli themselves, which are best studied where they are lying separately—in a hole in the blue, as it were. My chrysoidin slides certainly show them better on the whole; but I think this is simply and purely because the brown chrysoidin stain is fainter. As I said a fortnight ago, I can see them better with Gram's double stain than with anything else; and I have to apologise for an error in the description of the Gram, where, in describing the iodine fluid, I seem unaccountably to have left out the iodine. The receipt is: Water, 50 drachms, dissolve in it iodide of potassium 30, or, for single strength, 15 drachms. Then in this solution dissolve iodine 20 grains, or (single strength) 10 grains. The "single strength" sometimes acts sluggishly and imperfectly; and while it is always easy to weaken a strong liquid by merely adding water, it may be tedious to strengthen a weak one. And, finally, *Bacillus tuberculosis* is best seen in cultivations. With respect to comma bacilli, I think, before dismissing them with a verdict of not proven, another correspondent should read Mr. Watson Cheyne's articles in the *British Medical Journal*. However, I have never cultivated them, and cannot speak of their life-history at first hand. But if anyone wants to see bacilli almost like them—and yet not exactly similar in size or contour—he has only to examine, staining with magenta, a little of the sediment in the water with which he rinses out his mouth first thing in the morning. **F. Grant.**

## CRANK AXLES.

[24348.]—In reply to your correspondent "Crank Axle," p. 284, our mode of forging "The Fibrous Crank Axle" is as follows:—We first take a piece of iron and forge or draw it out in the usual way to form the shaft or axle (A, Fig. 1 on the accompanying drawings), leaving sufficient metal at two positions where the cranks are required, which we afterwards draw out, tapering at right angles to each other, thus forging the two portions (B) to receive the layers (C, Fig. 2) which we next forge with the grain or fibre of the iron running in the direction of their length; the layers are forged tapering, and of sufficient length to allow us to belt or clip them round the shaft in the welding up, and in them we form a groove or recess (D) at any required position by means of a V or other suitable tool in order to receive the billet or bar of iron (E, Fig. 3). This billet, which we also forge with the grain running parallel to its length, forms the journal or crank pin in the finished crank axle.

We now heat one of the tapered portions (B) of the shaft, and also the layers (C) and billet (E)



sufficiently to enable us to tack them all together. It is then placed into the furnace, and when of a welding heat it is brought under pressure and the whole formed into a solid mass (Fig. 4). This operation may be effected by the steam hammer, hydraulic, or other pressure. The other crank is next welded up in the same manner. The forging is now ready for slotting out and turning up, and the crank axle finished in the ordinary way.

Although in nearly all cases in which crank axles are made with our method of forging, it will not be necessary to twist the iron in order to obtain the right angles, yet in some incidental cases where the distance between the cranks is very small, it may be impossible to forge them without twisting on account of the difficulty of turning them in a furnace as at present used.

Please note in the above-mentioned drawings the shading lines are all drawn in the direction of the grain or fibre of the iron, thus obtaining the full maximum strength of the metal.

June 2nd. **Linney and Lawson.**

## CRANK AXLES.

[24349.]—I have been much surprised at the statement made by "Original Lockstitch," p. 302, that cranks break most in the crank-pins.

All our readers know where the Penistone crank went—just through the web close up to the crank-pin. That is the common place where they do all go. I only know of very few that went at any other place.

I also have the greatest faith in periodical examinations. I should like to know from "Lockstitch" how many per cent. are discovered on the Midland, because they claim the highest number on the Great Northern. Steel axles have broken on Midland engines 829, 61, 809, 823, 1104, 63, 1, 9, 73. We think it would be of value if "Meteor," "Lockstitch," or any other friend would give the miles run in each case. The new big 1667 class of 19in. cylinder engines have iron crank axles, and they seem better than steel.

The great question, as I take it, is "iron or steel"; but I don't find that "Lockstitch" gets on to this point at all; perhaps he will in his next.

I like iron cranks best, with hoops and four bearings, like the fine old 800's.

I don't agree with "Lockstitch" that forging iron to any extent avoids the fibres in the metal; it may compress them, but it does not remove them, and they ought to be all in the proper direction.

June 5. **Midland Driver.**

## THE BREAKING OF AXLES.

[24350.]—The Board of Trade returns relating to accidents during the three months ending 31st March, 1885, has been published. During that period 100 axles failed; 55 were engine axles—viz., 48 crank or driving, and 7 leading or trailing—3 tender axles, 40 waggon axles, 2 axles of salt-vans; 24 waggons, including the salt-vans, belonged to owners other than the railway companies.

Of the 48 crank or driving axles, 38 were made of iron and 10 of steel. The average mileage of

38 iron axles = 212,754 miles.
10 steel axles = 179,182 miles.

One of the broken waggon axles caused the waggon to be thrown foul of another set of rails at Penistone on the 1st January, 1885, when it was run into by a passenger train, four persons being thereby killed and 47 injured.

**Clement E. Stretton.**

Leicester, 6th June.

## RAILWAY-AXLE LUBRICATION.

[24351.]—In your issue of May 8th there is a communication (No. 24213) *re* above. And as no one has yet come forward to throw light on the subject, I will venture to give what I consider the best means of lubricating railway axles, but, with the writer of the letter referred to, think there is room for great improvement in this section of working.

The first question asked is, Which is the better lubricant—grease or oil? Oil is admittedly the best, but at present there is difficulty standing in the way of its general use—how to apply it continuously and yet economically. Capillary attractors, or wads, as they are called, are often made use of in applying the oil; but they have the great drawback of becoming glazed by friction against the journal, and when that takes place the flow of oil is impeded.

Another mode is to fill the cavity in the top of the axle-box with wadding or waste, and saturate it with oil, depending on gravity and shocks to carry the lubricant out of the sop down to the journal. But this is very unsatisfactory. Up to the present I have seen nothing to beat the arrangement used by the Midland Company for oil. A vessel, having one perforation in the bottom, and inside the vessel a small ball, loose, which, when the coaches are at rest, always takes a position covering the perforation, because of the concave shape given to the vessel's bottom; but when the train is in motion the slight shocks are continually moving the ball a little from side to side, allowing the oil to pass in sufficient quantities. It will be seen there is no feed unless the train is in motion.

With regard to the axle-box, I think a deal might be said, for upon the perfect working at that point depends the success of long-distance runs, in addition to the question of fuel consumption.

In designing boxes the points aimed at are, or ought to be, plenty of space for brass, strength with lightness, plenty of space for the lubricant, so that a good store may be carried, also good length of bearing surface, and care in deciding upon the width of sliding grooves.

As there are so many different kinds of boxes, and each one claiming the most advantages, I shall leave the matter of deciding which is really the best to someone whose experience has been wider than my own. **A. A. L.**

## AN ACCIDENT AT MANCHESTER.—TO "METEOR."

[24352].—The 12 o'clock noon train from St. Pancras, with engine No. 1666, ran into the buffer-stops at the Central Station, Manchester, on 24th April. Could "Meteor" oblige by stating why the accident happened, and what the Board of Trade inspector has reported on the matter?

**Passenger.**

## HEBERLEIN BRAKE.

[24353.]—I understand that a new form of this brake is in use on the Colne Railway. Is this brake the same construction as the Clark-Webb chain brake with automatic tight cord?

**Loco.**

## PARAFFIN LAMPS—GERMAN LATHES—A NEW CLOCK.

[24354.]—I am inclined to think that the heating of oil reservoirs does not cause so many explosions as general folly and ignorance. Petroleum lamps are used throughout this town, and the number of deaths from lamp explosions are very numerous. One of the chief causes of explosion is attempting to refill a lamp while burning, particularly cooking lamps. The lamps are all of the Silber pattern, with glass reservoirs and chimneys, formed at the bottom like the choke of a rocket. With cheap petroleum explosions will often occur when putting out the lamp, however carefully it may be done. Would it not be possible to fill glass reservoirs with sponge, so that if broken a spill would be avoided.

It seems to me strange that there is no plan for reversing hand planers. There is one Eckardt, of Stuttgart, who uses a system of clutches to reverse with; but his motion is patented, and his prices for complete machines do not suit my pocket at all. His machines run very lightly; but make a considerable pumping noise.

I was not aware that Messrs. Seidel and Walz, of Berlin, were leading makers of either England or of Germany. Most German lathes have the mandrel cones and collars dead hard, while the nose is tempered to blueness; but I never heard of their being trued with a diamond. The best makers are to be found in the Rheinland, not at Berlin. The Berlin makers have not the name that the former have.

In old German lathes the chuck-seatings are often 2in. larger than the nose. In one that I know very well there is the combination of cone, cylinder, and flat seating, which brings up the diameter of seating to about $3\frac{1}{2}$in.

About Christmas time I saw a clock similar to that described by "Garrison Gunner," in the shop of a clockmaker who makes paper clocks and such like novelties. The swan moved only every five minutes, and with a jerk.

2nd June. **A. F. Shakespear.**

## THE NEW TIME.

[24355.]—When I wrote my original communication on this subject (p. 36), my object was not to raise a discussion about it, but merely to advise astronomical contributors to this journal not to make use of the "new time" in their published observations without distinctly stating that they had used it; as it not having been generally adopted for astronomical purposes, their so making use of it would only lead to confusion. As, however, a very interesting discussion has been raised, and is now being carried on, I would like to make a few remarks, and having said all that it is, perhaps, necessary for me to say upon its advantages for the purposes of everyday life, for which purpose it must appear to every unprejudiced mind as admirably adapted, I will confine myself to that part of the proposed change which most affects the astronomer, viz., the changing the commencement of the astronomical day from noon to midnight, a point upon which, I think, I may confidently assert there is considerable diversity of opinion among those most interested.

As I remarked in my letter on p. 36, the advantages (?) to be gained by astronomers are of such a nature as to make it extremely doubtful whether the proposed change will be generally adopted for astronomical purposes; and though I have since then carefully read the Protocols of the Washington Conference, I can find no argument therein sufficiently strong to cause me to change that opinion. In the case of the phenomena of Jupiter's satellites there are great inconveniences attending the adoption of the "new time" by astronomers, as pointed out by "Conservative" (letter 24294, p. 282); the same inconvenience would attend the observation of an occultation of a star by the moon, as sometimes the disappearance of the star would take place one day and its reappearance would be observed on another; in these particular instances, and in observations of a similar character, the inconvenience would be great; but in the case of "a star observed at 11.59 p.m. would be different, for reduction, to one at 12.1 a.m.," referred to by "Conservative." I presume the difficulty is not so considerable, as the one star would simply be reduced for one day, and the other for the following.

We should, no doubt, soon get accustomed to changing the date in the midst of our observations; but it would at times be very inconvenient, to say the least, and the advantages, to my mind, are *nil*, excepting that the civil and astronomical day would agree, which, as astronomers are, comparatively speaking, a small body of men, and astronomy being a science, made a special study of by only a few individuals, I do not see that it matters much whether the two days agree or not. What astronomers choose to do as regards this point is a matter of indifference to the world at large, the only class affected by their decision being sailors, and they are, I believe, against changing the *Nautical Almanac* in this particular; at any rate, such of them as have spoken on the subject are agreed that if a change is made, it will have to take place some years hence, so that ample notice may be given, and the change made simultaneously in the various national ephemerides.

It is true, as Prof. Oppolzer says in his interesting paper in the March number of the *Monthly Notices*, that "Changes occur in other branches of science which necessitate more important alterations in the respective books . . . . without the least confusion arising"; but, with all deference to the professor, I may be permitted to point out that those branches of science in which changes are made without causing confusion are but in their infancy: changes are looked for by their respective students; but astronomy is an established science, and what is learnt by the earnest student to-day, has not got to be unlearnt by him to-morrow, as is the case with many branches of modern inquiry.

B. J. Hopkins.

---

## THE NEW TIME.

[24356.]—I see in your journal, of which I am a very old subscriber, a number of readers continually calling attention to the new method of time tables for railway travelling. In reference to the twenty-four-hour system, I feel convinced that it would never be safe to travel under such a system unless all the porters, guards, signalmen, and others connected with the various railways were educated to it. I have travelled upwards of a quarter of a million of miles, consequently know something of travelling. I see a great many suggestions are made of printing time tables—some suggesting a thick line for the a.m. and a thin line for the p.m. This would be entirely useless, as the distinction would not be observed. I now beg to inclose you one of my new patent time tables, by which you will see at a glance the difference between the a.m. and the p.m. I simply print the a.m. time in black ink, that is, from twelve o'clock midnight until twelve o'clock midday; and from twelve o'clock midday until twelve o'clock midnight, which is the p.m., I print in red ink, therefore showing at a glance that the a.m. trains are black ink and the p.m. trains red ink. Should any of your correspondents like a copy I shall have great pleasure in forwarding one.

William Kloen.

Renwood, St. Peter's-road, Handsworth,
Birmingham.

[Capital for small card time tables and the like, but the objection from a printer's point of view in case of book tables is very obvious.—Ed.]

---

## LATHE MATTERS.

[24357.]—This lathe talk seems like to end in nothing, as so many previous discussions have done; and out of the intolerable amount of talk, we shall get not even the miserable halfpennyworth of solid food. Surely in a practical journal we ought to get more definite results. Yet subject after subject passes under review, and there is no Q.E.D. reached to mark a stage in our progress, if indeed we make any.

First, as to screw threads. Has anyone introduced a new system? What is it? Is it growing in public favour as a substitute for *several* others?

Next as to the front slide lathe. What makers are making it? How many have been made since the discussion, and to what patterns? How do the users like them?

Thirdly, the "interchangeable" or "model mandrels." Who are making these as a regular article of trade? How many have been made? How are they liked? What are their exact dimensions? Also, does Evans or Hines send out chucks to gauge, guaranteed to run true, and a perfect fit, without seeing the mandrel, merely knowing its dimensions? If not, when will they advertise to do so?

The above have been talked to death, and as the questions left are workshop details, it seems time for practice to step in and solve it *ambulando*.

Now, in the present discussion, as usual, we wander from point to point, and so have contrived to muddle up three issues in one. Let us separate them.

First, then, can screws be cut with circular cutters? Square threads apparently cannot, V ones can under certain conditions. But the point is, Can the ordinary threads be cut (as well as) or better and more easily in practice with circular cutters than with the chaser or point tool? Well, then, let Mr. Hines, Mr. Evans, or Dr. Edmunds cut an inch bolt, and send it, with [illegible], to some central spot, where all may see it for themselves—say, to some stall at the "Inventions." It would be a good advertisement, and settle the question once for all.

A second part of the same question is the desirability and possibility of cutting and trueing hardened steel taps or screw-threads by laps and diamond dust. Again I ask Mr. Hines what firms do this for their taps, standard or otherwise? Also, has it been done to mandrel-noses, or is it a suggestion at present untried, and possibly unnecessary?

A third part is the trueing of hard steel by the fixed diamond tool. Mr. Wenham has, to some extent, settled this, and we can trust the accuracy of his work; but it would be more satisfactory if someone else could testify to the quality of this steelwork, and if the makers would write a line or two on their mode of working. Personally, I accept Mr. Wenham's statement, and trust his judgment.

And now, before saying anything on the question myself, I would thank those who have kindly answered my questions. I thank Mr. Hines for the offer of a piece of mild centred steel; but I did not want a proof of its quality, or existence, only to know where and how we amateurs could obtain it. This we can all now do. Mr. Wenham and "J. K. P." have been such true friends to us that I am now going to beg again, and let me assure them that my memory is not astonishing, seeing that I and others have so few letters on which we can implicitly rely—I know his by heart. My present want is a good scale drawing of a back-centre mandrel for 3½in. or 4in. general lathes. What are the advantages of a long mandrel, and beyond what limit is the gain not worth the candle? Is there a serious objection to saving cost of *bed* by cranking back the fixed head-slot, as in the "Harmonious Blacksmith's" design? What are reasons for and against the *centre point* being on mandrel Holtzapffel fashion? I see that the back support can be drilled for oil—but what else? What is a good section for bed for general lathe, as regards proportionate depth, breadth, and thickness?

As regards the lathe-nose and circular cutter question, I have nothing much to say. As to centring chucks, the Doctor says I confused two kinds of centring; but I don't think so. He said the screw was everywhere rejected as a centring agent, meaning, it seems, only as regards what he calls "predicable" centring, and I, objecting to the unqualified statement, asked what gave the centring in the Holtzapffel nose, and he answers, the screw; but that he did not mean centring generally, only predicable centring. Just so; that is all I wanted.

Nevertheless, most of what I said will suit "predicable" centring also. In fact, it is only a question of truth and gauge, and has not yet been often attempted; but that it is attainable Mr. Hartley has shown as regards the geometric chuck, and "J. K. P." as regards ordinary high-class work, which is good enough for most of us. But having said this, there seems little doubt truth and gauge may be attained and retained more easily by a cylinder and face than with a screw; but at the expense of simplicity, and, I think, of strength also, as well as of ease in the fitting of chucks. For ordinary work, I feel sure the plain screw will hold its own, and whether the new or old is to be used for ornamental work must be settled by experience.

As to the circular-cutter business, the Doctor is so clear usually in theory, that I am surprised he stated that the height of the cutter above centres makes no difference. Most certainly it would alter the rake, and deform the thread, as others have said. Doubtless it was a slip; but he should have withdrawn the statement. "J. K. P." seems to me to have been, I won't say wrong, but verging on error in one point also; but I see, by to-day's paper, he and the Doctor have settled their differences (or some of them), and that he intends to say no more. Just as I expected, we are to get nothing definite out of the talk. Will he, as our guide, kindly give the results at which he has arrived? Paley says that seeming discrepancies, shown to be really close agreements, are the strongest evidence of the correctness of the statements, proving that even bias could not affect truth. If, then, Dr. Edmunds and "J. K. P." will write a joint set of propositions to which they assent, we humble disciples will have something on which to pin our faith.

Bow.

## CUTTING SCREW-THREADS.

[24358.]—The value of a screw-thread derived from an isosceles triangle of 50° and truncated 7½ per cent. of its base, i.e., an angular thread whose altitude is equal to the length of its base, is one question. The methods by which this or any other screw-thread can best be cut is another question, yet we seem in danger of getting the two questions mixed up.

I have never proposed that ordinary screw-cutting should be done otherwise than by an ordinary angular point-tool fixed in the slide-rest, and tilted to the rake of the thread. But in order to meet cases which cannot be met by the ordinary methods, I have suggested that certain angular threads may be trued up by the revolving cutter or revolving lap-wheel used as a glazer, and armed with a very fine abradant or a polishing powder. The applicability of this method depends upon the various factors which I have already referred to. With a square thread the revolving cutter cannot clear itself, except by deforming the section. With an acute angular thread the revolving cutter cannot clear itself unless the pitch be very small. What we are discussing is the applicability of this method to the truing-up of angular threads of 50° and more, and of such pitch as would be used on a mandrel-nose.

As to the threads of this character which I had cut by this method, "Vulcan" has favoured us by examining them and reporting upon them (page 280 and 281). He writes as follows:—

"Last week I examined specimens of the actual Edmunds thread. The thread is as described—beautiful; its clean, sharp appearance being enhanced by the very slight, almost infinitesimal, concavity of the thread-face on the axial section. Two screws, with their axes parallel, and teeth engaged, just show this curve with a light behind and a watchmaker's lens in front—this looking along the inner tangent to the contacts in axial plane not *point* blank. Practically, this minute concavity is the sum total of the case against it. The thread is reversible—faultlessly so."

"Vulcan's" second letter (page 281-2) reads as if written with the assistance of a fit of the gout. This is fortunate, as showing that his testimony on the other matter does not need discounting. So long as our criticisms are kept within academic lines, entire freedom of expression is conducive to free healthy discussion, and it leaves us the more free to comment upon each others' notions. All I need ask is, How many screws will bear the test to which "Vulcan" has subjected mine? Then, again, Mr. Boord has kindly cut me two specimens of screws by the method now so vigorously attacked. One is an ordinary screw of typical "angular thread" of 50°, making three turns per inch on a cylinder 1·25in. in diameter. The other is a three-thread ·8in. twist drill, each groove having a rise of about ·7in. per turn. Both are exquisitely formed, and both were cut by means of the same fly-cutter—a sharp V-point tool of 50°—merely tilted to different angles, and speeded at different rates of traverse. Mr. Boord has kindly given me permission to submit his screw-models to the Editor.* Any one may now see twist drills being shaped by revolving cutters in the machines at work at the Inventories, and there can be no doubt that, with a clear understanding of the geometry which is involved, the method is one capable of doing work which no other methods can accomplish.

*Section.*—The question of what we are writing about when we apply this term to screws and screw-threads needs careful consideration. There is only one section to be practically regarded in a *screw*, and that is the section made by an axial plane—the *axial section*. The outline of the thread-section shown on this is, however, not the section which has to be practically regarded in the *screw-thread*. This is the *normal section*. Now, the normal section, or true cross-section of the screw-thread, is a plane only in one case, i.e., when the thread is an annulus returning into itself, and there is no *traverse*. Here the axial section is also the normal section. In all cases where the thread is a real screw-thread, i.e., when it has a longitudinal component put into it by the traverse, the normal section is *a screw-surface*, not a plane. If the thread is to be calculated from the axial section, the cutter must be used as a chaser is used in the slide-rest, i.e., it must have its cutting surface plane, not tilted, and be put into cut on an axial plane. In this case the base of the normal section of the thread will be the cosine of the base of the triangle of the V-point tool with which the thread was cut. Here the length of the cosine depends upon the pitch of the thread, and is got from the "hypothenusal line"—this being the hypothenuse of the right-angled triangle whose base is the length of the circumference of the pitch-cylinder, and whose height is the traverse made by one turn of the thread. But the shape of the normal section under these circumstances is really a helicoidal projection-form derived from the cutting face of the tool: its cosine base will therefore be twisted into a helix.

---

* Certainly admirably executed.—[illegible]

*Thread-form.*—The form of the screw-thread is only in special cases a counterpart of the form of the tool with which the screw-groove is cut. It is a mistake to assume that a triangular or square tool cuts a screw-thread of the same form. If, for instance, the extreme pitch of a fluted column be considered, it will be seen that here a square-ended cutter, if entered so deeply as half the radius of the cylinder, will have undercut so completely as to detach the threads at their bases and leave them standing as triangular prisms connected with the cylinder only at their ends. Similar considerations have to be taken into account in the case of every screw-thread; but the subject is too abstruse to be dealt with now. It must, however, be dealt with if we are to understand this question, and "Vulcan," when convalescent, will no doubt kindly pioneer us. Perhaps, meanwhile, "Vulcan" will explain his tool more fully. But I fear that most screw thread forms will turn out to be "unnameable," except by some such agglutinate designations as moderns chemists have to produce so largely. Oh! that mine enemy would write a book! I agree with "Vulcan" that "it is beyond our mathematics to deal with a diagonal normal section cut by a plane." The normal section is, as I have already shown, always a screw-surface and never a plane. The base of the normal section is also always a screw-line, and never an ellipse. The elipse formed by the diagonal section of a cylinder has nothing to do with a screw-thread. That a helix is the shortest line between any two points on a cylinder is easily shown by developing the cylindrical surface, when it will be seen that the helix becomes a straight line, whereas the ellipse becomes an undulation-curve.

Mr. Wenham favoured us with another letter at page 237 apparently for the purpose of showing how cleverly he can "put his foot into it." His teaching is this: "If a rotary cutter is set just to scrape the surface, it must be set exactly at the angle, for if either more or less, it will trace a pathway wider than the cutter." Now, if any reader will take up a round ruler and hold against it the square end of a carpenter's chisel, he will see that only when the edge is in an axial plane can it be made to "just scrape the surface" for its full width. If it be set "either more or less," the width of the scrape will be *less* instead of more. And if the chisel represent a revolving cutter acting upon a rotating cylinder, it will be found that its square end, when tilted, will cut a hyperboloidal or dice-box bottomed groove. But this, again, is only an illustration that the tool-profile, projection-forms, and intercepts, all have to be taken into account if we are to predict the true form of the cut which we get in cutting screw-threads.

The screws cut by myself, those recently cut by Mr. Boord, and the V-point cutter with which they were cut, remain at the office of the ENGLISH MECHANIC, and may be examined by anyone interested in defining the facts.

**James Edmunds.**

Grafton-street, Bond-street.

### CUTTING SCREW-THREADS.

[24359.]—IN answer to "J. K. P.," page 280, I was myself surprised to see the words mentioned in inverted commas. I intended them to have been in italics, and to that end underlined them in my letter. This I still hold to be the usual way to denote italics, and have since had the opinion of a competent London compositor, whose words were: "Once underlined, italics; twice, small caps." So it is our printer.

Respecting the next part of "J. K. P.'s" letter, I still cannot see why a circular cutter cannot clear itself in a V-grooved, moderately-pitched screw. Take now any ordinary V-thread screw, and hold it between the eye and the light, inclining it so that the line of sight is in the same vertical plane as the rake of the thread at the top of the screw, and so that the sides and bottom line of the thread-groove can be seen; a plain V-gap will be seen with straight sides; and this I take it is the exact V-line which a circular cutter will work upon when used to cut that thread, and it will touch nowhere else.

Again, take a screw held between centres in the lathe, and let the fixed tool, which has just cut that thread, be set to just touch the bottom of the thread-groove; is it not plain that if the tool be either raised or lowered in the line of the rake of the thread, it ceases to touch the thread in any part, and this without any "Faugh-a-Ballagh" principle being brought into play, much more will it clear if the tool point be raised or lowered about a point in its shank as a centre, thus constituting a revolving cutter, and whether wheel or single fly-cutter matters not, the action being the same?

There seems to me one point entirely overlooked, and that is that a wheel-cutter can only touch the bottom of the thread-groove in a point, not in a line, as some of our correspondents seem to think, to judge from their arguments.

I am, I am sorry to say, too busy just now to write as I should like, and shall have barely time to catch the post so that this may appear this week, so any defects I must ask to be pardoned; but I think my meaning is plain enough.

**Hadah.**

[24360.]—MY letter (24293, p. 281) appearing, requires a few corrections, and a note or two: Line 9, 3rd column, "coupled" should be "angled." Line 30, 3rd column, "screws" = "screens." I do not now remember how I got the dimensions of the "critical" screw, p. 282, but they seemed approximately correct at the time I wrote them down. Some confusion of the "other-handed rectangular helixoid" for the "other-handed normal rectangular helixoid" has seemingly occurred. The principle is not, however, much affected by my pen-and-ink screwology, and spiro-spiroido-linear, helico-helicoido superficial trig. is fatiguing, and not yet at my fingers' ends.

Last but two paragraph, after "grinding" should be "period," and following it should read "At their best, &c." Next line, "same velocity" should be "slow velocity," and "centrifugal" should be followed by "and gravitational." The comma after "action" I hope I am not responsible for, and it should be omitted.

**Vulcan.**

### POSITIVE AND NEGATIVE LENSES.

[24361.]—THERE seems to be a good deal of confusion in the use and meaning of the above terms as applied to lenses, which is much to be regretted, as they are useful forms of expression, when one simply means to indicate the general character of the lens without going into detail.

Sir John Herschel uses the words in what I consider the only reasonable and proper way. He describes a positive lens as one "having a convex character, tending to produce convergence" ("Telescope," p. 101). This seems all right and intelligible; but when we come to study the textbooks on optics we find that the writers do not quite seem to have the same opinion about the matter. In Parkinson's "Optics," p. 93, we find it stated that the focus of a lens is positive or negative, according as the lens is thinnest or thickest at the axis, and that "a lens whose focal length is positive is called a concave lens; one whose focal length is negative is called a convex lens." Of course a distinction may be drawn between a positive lens and a lens with a positive focus; but in ordinary conversation I consider that the same thing is meant, and that a positive lens is one with a positive focus, and this we are told in the textbook I have mentioned is one which is thinnest in the centre, and is a concave lens.

In Glazebrook's "Physical Optics" the same thing is stated: "the focal length of a concave lens is positive, that of a convex lens negative."

Turning to another subject, I see it stated in Prof. Newcomb's "Astronomy" that Alvan Clark's object-glasses are all formed on Littrow's plan, an equi-convex crown, and flint with the same concave curve and flat back. As these glasses are of acknowledged excellence, it is clear that quite as good a glass can be made upon this plan as upon Barlow's.

**Ascalon.**

### CRAMMING IN PHYSICO-MATHEMATICAL SCIENCE.

[24362.]—IT is truly painful to observe to what a deplorable extent the modern examiner and the educational writer jointly play into the hands of that pernicious institution, the crammer "for all exams."

I have before me a much-belauded textbook of natural philosophy—a work which I believe finds favour with the authorities at the London University and elsewhere. Now this book, although excellently illustrated and clearly printed, is perhaps the most flagrant and mischievous specimen of the "Crammer's Assistant" now extant, and this is saying a good deal. Full of rules and formulæ, there is no attempt whatever to give the *rationale* of any of the processes indicated, nor, in fact, to teach anything beyond blind dependence upon memory alone. Plane trigonometry, it appears, is *not required* for the first London exam.; accordingly, we find in the work in question that the principles of mechanics, &c., are laid down (?) without reference to that branch of science, or to the fifth and sixth books of Euclid's Elements, which are, I contend, indispensable, if anything like a clear understanding of the subject is aimed at.

I have under my observation a youth of more than average intellect, whose brain is now, I fear, hopelessly bemuddled through an early and injudicious course of data and formulæ. Propound to him some simple mathematical problem, and he will reply with an air of great uncertainty, "*the formula is so and so, is it not?*" or, "I can't manage it, I have forgotten the formula;" or, worse still, he will straightway pick out from his superabundant but rather mixed store of rules the wrong one, and laboriously work out some absurd result. Now, if it is only sought, at the outset, to give a lad a sort of general view of the sciences included under the head of natural philosophy, why not direct his attention to such works as the late Dr. Paris's "Philosophy in Sport made Science in Earnest"? Or if, on the other hand, it is required to impart serious and solid instruction, could better masters be found than Wood, Whewel, and Phear, whose simple yet scientific methods leave nothing to be desired? We have, too, Deschanel, whose work on physics has been very well translated, and the noble work of Jamin, which it requires a very slight knowledge of the French language to read and understand.

June 6. **Recte Faciendo Securus.**

### COL. ROSS'S FILTER PIPE.

[24363.]—MAY I be permitted to add to the excellent description of this pipe in the ENGLISH MECHANIC, p. 295, that, if the sponge in the improved form is made according to the description there given, and placed so that its broad end obtrudes from the mouthpiece part of the pipe when unscrewed about one-tenth of an inch, the latter part is used (by me) *as a brush*, with which I paint the inside of the hot bowl, after a smoke, and the thin layer of ash has been gently scraped off with a penknife?

The result of this operation is that the condensed "oils" containing the nicotine are absorbed by the distended pores of the hot briar, and, being incombustible, or nearly so, not only preserve the briar from burning, but prevents all caking—i.e., coating of the interior of the bowl, after a few smokes, with a hard crust of conglomerated tobacco-ash, charred briar-wood, "oil," and saliva, which can only be removed afterwards by the application of a strong knife with great force, and the removal then generally destroys the bowl. In a pipe so treated the tobacco will be found to burn *regularly* downwards, with a clear ring of demarcation from the inner surface of the bowl, to smoke much "sweeter," and to consume to the very end, leaving no "plug" of moist tobacco at the bottom.

It should be remembered that the interests of the smoker (in which I now write), are, in this case, diametrically opposed to those of the pipe maker and of the tobacconist, whose chief object, of course, is to sell as many pipes and as much tobacco as possible. Nine-tenths of the former class object to taking any trouble with their pipes; or, as they call it, to being "bothered with them." But a little reflection will show them that there is much more "bother" in neglecting a pipe than in thus taking care of it, as pipes thus treated never become foul; at least, if they have the double-sized bore, with the necessity of which I have tried (hitherto in vain) to impress the makers. The horrible smell of these "oils" condensed on the sponge is, I admit, the greatest defect of my pipe, especially to surrounding non-smokers, but the following plan, which I have carried out in the midst of crowds at the Inventions Exhibition gardens, without anyone being aware of the fact, seems to obviate it. When I find (by a slight obstruction in the draught) that the sponge is becoming saturated, I unscrew the mouthpiece, press the obtruded sponge firmly against the ferrule-end of my umbrella or walking stick, held perpendicularly downwards, and blow strongly through the former, when the accumulated "oil," saliva, &c., drops to the ground; the smoke is then continued with increased pleasure.

**W. A. Ross.**

### THE MICRO-OBJECTIVE.

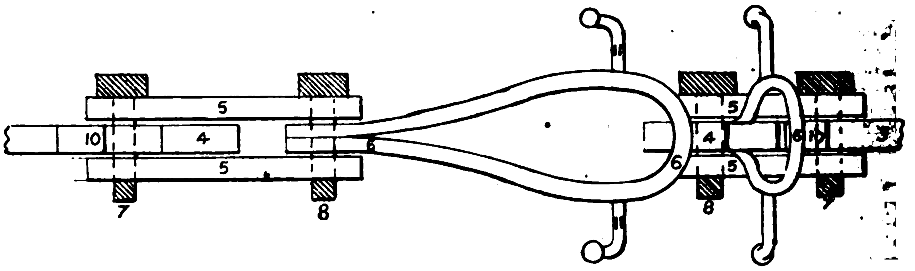
[24364.]—BEFORE grinding a flint concave it will be well to have a little practice at the plane side, as that is more difficult than the curve.

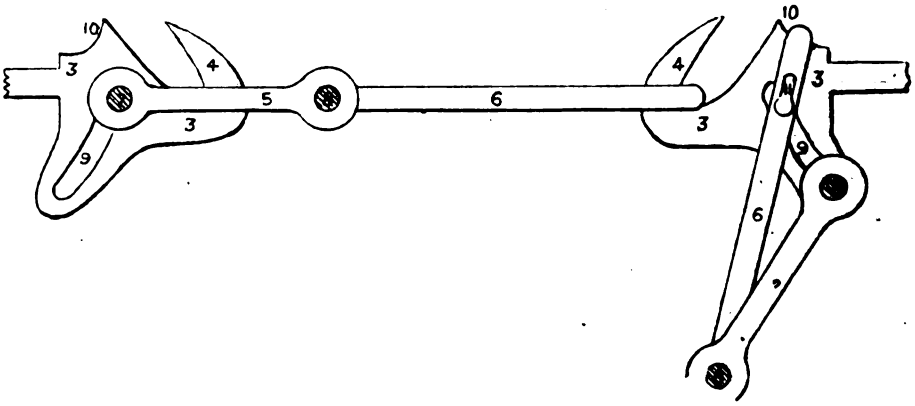
Take a little plate of flint-glass as described in our last note; stick with pitch or sealing-wax a small block of cork or wood to its centre, about ¼in. diameter, but as thin as it may be, and yet serve as a handle by which to work the glass on the laps. If this handle be at all high, it will tend to tip the glass on to its edge, which is to be avoided as much as possible.

Now rub the face of the glass on a level piece of iron with emery powder if it require it; that is if it be very rough, and when level, smooth it as much as the powder employed will allow. Spread some flour emery and water over a piece of thick plate-glass—any old stuff from a broken window will do—with water to form a thin paste; work the ground face of the future lens on this until it is free from all trace of scratches, and perfectly uniform in grain under a magnifier.

Turn the piece of plate over, and anoint its other side with washed emery and water, and working the ground face of lens hereon, produce as fine a surface as possible.

It is in this fine grinding that the Pons Asinorum lies. Get over this, and the remainder of the journey is easy. When the finished surface is examined with an inch focus lens, there should be no inequality in the grain, no cobweb-like lines, no tiny pits left by the emery grains, and, as a further test, note at what angle window bars may be seen by reflection therefrom.





I once saw it stated in "Ours," in reference to specula, that "the window bars were seen reflected from its ground surface, when held so that the light of the window fell upon its surface at some 30° or 60° from its perpendicular." Now I have generally been able to get my little flat surfaces fine enough to show window bars by an almost perpendicular incidence, that is as near to it as the head of the experimenter allows.

The object in getting a very perfectly ground surface is twofold—1st, it saves time in polishing; 2nd, it is a true surface geometrically, and will remain so if not polished too long; but prolonged polishing tends to make a convex surface of a most nondescript character.

Now for polishing. Cut a nice square of plate-glass, about 6in. by 8in. will do, and let it be thick. The wheel glass-cutters will cut anything up to an inch. I have done it; but ¼in. will do for this job. Now cut a piece of clean, strong paper about the same size, and stick it by one edge only to the glass; the other end must be held during the polishing. Cover this paper nearly with washed rouge, well rubbed on dry, and the loose powder shaken off. On this as a lap polish the lens by straight strokes; but be careful to turn it every few rubs, so as to get the cuts in every direction. There should be no fresh application of rouge required, nor should the paper be at all worn by the time the glass is brilliantly polished. The convexes and concaves are polished in the wet way on pitch tools moulded on the lens while warm, and used when cold again, with rouge and water.

In my next I will give curves and method of combining and arranging a modern o.g. with a method of testing. After which, with a few general cautions to be observed in working the curves, I shall conclude, unless anything further is asked for, in which case I will, with pleasure, add the information required. **Rob. Crus.**

# REPLIES TO QUERIES.

*⁂ In their answers, Correspondents are respectfully requested to mention, in each instance, the tit e and number of the query asked.*

[54698.]—**Round or Around.**—Although I introduced this discussion, it seems hardly suited to these pages. In one or two of the instances quoted by James Bird the word "around" seems permissible, and I have not said that the word should never be used. What I object to is its constant application in every instance, which is the case with an American paper which I have just been reading. "The circle around where the earth and heavens seem to meet," the second of Mr. Bird's quotations, is a miserable attempt at composition, quite beneath criticism or notice. Isolated instances don't justify the constant use of any word. The mention of Spenser, and the word "abed," reminds me of an answer by an Irish newspaper to one of its correspondents concerning the pronunciation of the word "Sardanapalus." Byron somewhere makes it rhyme with "ale 'us" (or some similar word), and the editor kindly informs his friend that "our English brethren pronounce alehouse 'ale 'us.'" The word "around" is only admissible where motion is neither expressed nor understood, and even then not in all cases. "Around" is, in my opinion, on a par with "agoing" and "acoming." I would say more on this and kindred matters; but I think it is considered rather outside the scope of the English Mechanic.—Os.

[56474.] — **Training for Athletics.** — This querist should procure one of the little handbooks published as guides on training. He must please himself as to what directions he will follow; but all the training needed is steady practice and attention to diet. Don't attempt to run at high-pressure speed at first; but work up gradually until you think you are perfectly fit. There is no "secret" in training; but the practice is a little different when training for a 300 yard burst and a ten mile race.—Nun. Dor.

[56475.]—**Nitrate of Iron.**—I venture to reply to this query, because I note the appeal of Henry Holmes on p. 307. He does not say whether he wants a ferrous nitrate or a ferric nitrate; but he does say that it must be made without copperas, which at once puts aside the easiest way. It can be made by dissolving ferrous sulphide in nitric acid; but the price at which it is sold shows that it is probably some by-product, or is at least produced where nitric acid is cheap—probably in factories where nitrate of soda is acted upon by sulphuric acid, and the nascent nitric acid is used to dissolve clean scrap iron. It would seem to be necessary, tco, to state for what purpose the "iron" is wanted, as dyers prefer a different nitrate for printing blue to that used in printing black. Perhaps, however, some of our chemical friends can help now.—Nun. Dor.

[56478.]—**Spectroscope.**—The prisms are long enough; but it is doubtful if they are right quality of glass or ground to the right angles. Cut by holding them against a disc of copper, with oil and fine emery on the edge, and revolving rapidly in the lathe.—Selim.

[56482.]—**Painting on Calico.**—Suppose this querist tries sizing his cloth before painting it? If necessary, the size can be taken out after painting. —N. E. Child.

[56486.]—**Pressure.**—If the dimensions were given, it would be possible to calculate roughly the power by the number of strokes of the handle; but that would necessitate the work to be pressed always being of exactly same dimensions. I suspect the only way is to have the pump fitted with a gauge.—N. E. Child.

[56487.]—**French Polishing.**—This art has been so often described in back numbers that "Turk" must expect to be referred to them, unless he will put some specific question, and also say in what way he fails. The work must be properly stopped first of all with whiting and tallow, plaster of Paris, or size for common; then with a pad of cotton wool saturated with the polish, and covered with a bit of clean calico, with just a touch of oil, coat the whole surface of the work with polish, and leave it to sink in and dry. Then paper down, and proceed to prepare for the polishing proper. Don't put so much polish in the rubber this time; always have the outside cover easily movable with just a touch of oil on it, and rub in circles. To finish you must have "finish," and use that the same way as the polishing coat, but not rubbing quite so hard. Nun. Dor.

[56493.]—**Waterproofing Tennis Racquet.** —I don't suppose that the gut was waterproofed in the sense usually given to that term; but it was probably well dressed with nut or poppy oil.—J. F. L.

[56580.] — **Tricycle Pedals.** — Turn a brass washer of a suitable size and thickness, cut a narrow groove on the edge; then cut the washer in half. It should then be placed in position, and a fine wire passed round in the groove and soldered. Another plan would be to get a small clock spring of the width of washer required, and wind round and solder the end. I have tried both the above, and am in favour of the former, which will answer well if put on square with pedal and kept lubricated.—Jack File.

[56582.]—**Safety Couplings.**—We beg to forward the inclosed drawings and instructions of our improvements in couplings for railway vehicles, now at the Inventions Exhibition:—Fig. 1 on the accompanying sheet of drawings is a plan, and Fig. 2 a side elevation, of our improved coupling. Our improved draw-hook, piece 3, is formed with a hook (4) to receive the end of a link piece, or a link of the chains at present commonly in use. This linkpiece is formed, as it were, of two link-like parts, 5 and 6, the first link, like part 5, being formed of two parallel rods of wrought iron, held together at each of their ends by wrought-iron pins, 7 and 8. One of these pins (7) is passed through a slot (9) formed in the body of the draw-hook piece 3, and the pin 7 is passed through holes formed in the ends of the parallel rods, which are thus connected together, one on each side of the draw-hook, leaving sufficient room for clearance. The pin 8 is passed through the holes formed in the other ends of the rods, and also through holes formed in the ends of the link-like part 6. This part 6 is formed by a rod of wrought iron bent into a loop, and having its two ends brought close together side by side, and placed between the ends of the rods of the part 5. The loop of the part 6 is formed nearly oval in shape, so as to admit of its being passed either over the hook 4 for coupling purposes, or over the hookpiece 3 for hanging on a small curved projection (10), when the link piece is not in use. When the part 6 is hanging on the curve projection 10, the pin 7 in the curved slot of 9 falls to the bottom and backward end of the slot. The slot 9 is so formed that when the linkpiece is coupled to another vehicle, and the distance between the two draw-hooks of the vehicle is lessened by any cause, the linkpieces, 5 and 6, will by its own weight tend to bend at the joint formed by the pin 8, whilst the pin 7 at the end of the part 5 will fall downwards towards the lower end of the slot 9, thus effectually preventing any chance of the link piece jamming. At the widest part of the oval or looped end of the part 6, there is formed at each side a short handle or projection, 11, for the use of the workmen when coupling or uncoupling with a stick from the outside of the vehicles.—Keeling and Rigley.

[56604.] — **Differential Equation.** — Much obliged to "M.I.C.E." for his reply. As he says, there is a misprint, the equation being $\frac{d^2y}{dx^2} - a\frac{dy}{dz} = 0$. The equation is that of distribution of potential of an alternating current, taking into consideration the capacity of the circuit.—H. H.

[56620.]—**Steam Carriages.**—"Nun. Dor.," answering on p. 286, concludes by expressing an idea that they will never become an "institution unless they run on rails." The word "rails" I suppose to mean iron rails. Would "pavement" answer the same purpose, providing it is of iron, on which vehicles of any gauge wheels could run as they pleased? Or does his idea include that the wheels must be flanged? Then comes the question of relative utility of flange and flat-tire wheels. Given a flat surface of iron for the wheel-bearing, can any amount of flange and groove improve upon it? And for speeds under ten miles per hour, would not the flat-tire vehicle have considerable advantages over the flange wheel, both as to requiring less motive power, less wear to both rail and wheel, and in being able to alter its course in the road? His letter shows there is no lack of means of providing different mechanical motive power for roads, providing there was the iron bearing for the wheels, and certain unjust restrictions removed from using them. Considering there has never yet been an Act of Parliament made for regulating the general traffic on highway roads, it may be near time such was done; and the removal of the unjust restrictions merely requires the voice of the public raised against them, and if shown to be unjust, there is no authority in England that could uphold them. The probable advantages of using mechanical motive power and providing iron tracks or bearing for wheels generally on highway roads are very great: 1st, the results of all motive power being increased (say) four times on iron bearing; 2nd, mechanical motive power being one-half less cost than animal horse-power; 3rd, the results of pedal power (as yet in its infancy) would also be increased four times on a suitable iron bearing; 4th, the wear of common roads is as much from horses' shoes as from wheels of vehicles; 5th, that 57 per cent. of the dust and slush of roads is caused from horse-droppings, which nuisance would be removed; and considering that all the traffic on railways is done on about 1ft. wide of bearing surface, and our roads we maintain 20ft. to 30ft. wide for a much less traffic, it shows that great improvements can be made in our road regulations if people's attention could be attracted to the subject, and a great impulse would be given for the construction of innumerable vehicles of many descriptions. At Portsmouth and Southsea there is now going on a "tug of war" between flat-tire and flange wheels. A number of well-appointed omnibuses with wheels of same gauge as the rails are running opposition, and using such parts of the tram-line as answers their purpose, and the public quite appreciate the prospect of this break-up of monopoly.—PROGRESS.

[56620.]—**Steam Carriage.**—The reply of "Nun. Dor." to this query is certainly very one-sided. He mentions that about fifty years ago steam carriages ran on turnpike roads with good success, and leaves his readers to infer that it was owing to some defect discovered in their working that they were given up. But the truth is far otherwise. Sir C. Dance, in 1831, ran a steam carriage from Gloucester to Cheltenham. It ran for five months without the slightest accident, and only ceased after the most determined opposition that it met with. The opposition took several shapes. Many turnpike bills, imposing heavy tolls on steam carriages, were quickly passed by the influence of those who thought their interests were endangered by the establishment of steam carriages. These tolls amounted in some cases to £2, and in some exceeded £3 at each gate. But his opponents were not satisfied with this. Large heaps of stones a foot and a half high, were laid right across the road in several places; from the arrangement of the stones the heaps could be intended for nothing else than to prevent the steam carriage running. It successfully surmounted these obstructions several times, but at last the axletree broke, and the combination against the steam carriage was too much for it. I have given this instance, but it is only one of many. Good speed has been obtained by steam carriages, even 35 miles an hour, and old Highgate-hill has been ascended with a gradient of 1 in 9. And then as to cost; in the Cheltenham coach above mentioned, the fees were half those of the ordinary coaches. Steam carriages are accused of doing more damage to the road than horses drawing ordinary carriages; but I do not think that this conclusion will be arrived at by anyone who considers the question without prejudice. In the case of horses, progression is made by repeated blows from iron shoes, while in the case of a steam carriage the wheel simply rolls. It may, perhaps, be urged that the wheel may revolve without moving forward, or out of proportion to the forward movement; but there is no need that this should occur, as the wheels may be widened, and thus more grip obtained at the same time that the road would be less worn. Moreover, if steam carriages were used universally in the place of horses, the asphalte and other such pavings could be much more used, as the chief objection to them would be taken away—viz, the slipping and falling of horses; and thus, the roads being rendered less irregular, the wear of any tires considered necessary for steam coaches would be much diminished. And now as to the tires: "Nun. Dor." says "no steam carriage can be successful on a common road, unless it has thick rubber tires or elastic wheels, which, so to speak, lay down the other 'element' in the shape of a rail." This is by no means yet proved, and I venture to doubt it *in toto*. None were used by Gurney and Dance, and their success is indubitable to anyone who will take the trouble to read the whole matter. I have hitherto spoken of *steam* carriages, but I am by no means certain that steam will be the most suitable one in the future, though it is so at present. The invention of electric accumulators within the last few years hold out a hope of the utilisation of electricity for such purposes, though at present the accumulators are almost practically useless. I cannot concur in "Nun. Dor.'s" opinion that the whole subject was thrashed out half a century ago. We may not have progressed much in this direction during those fifty years, but progress there certainly has been.—GWYLLM MAESGWYM.

[56620.]—**Steam Carriage.**—I observe further correspondence on this subject. There is much misapprehension as to the effect of the judgment against Sir Thomas Parkyns. It is true that he was fined a shilling, and that his appeal was given against him; but as there is no "informers clause" in the Highways Act, and the police have no right to interfere, it is highly improbable that much trouble would have resulted from this decision except in case of accidents from misfortune or recklessness. The real reason of the disappearance from public view of the "Baronet" motor tricycle, of which Sir Thomas Parkyns was the patentee and I the godfather, are of a different character, as there are many who would have risked infringing the Highways Act, and also others who have private grounds, exporters, foreign buyers, &c. Indeed, my firm received many positive orders from abroad. I have no doubt that satisfactory steam tricycles can be made, but I am equally certain they will never come into common use. With your permission I will give my views on the subject of the necessary qualifications for such a machine:—1. Must be easily worked by anyone, whether an engineer or not; 2. Absolute safety; 3. So constructed as to be impossible to work it wrong, remembering that many people prefer doing a thing wrong to right; 4. Durability; 5. Reasonable weight, having regard to occasional necessity of personal working; 6. Entire absence of visible smoke or steam; 7. Satisfactory condensing arrangements, as water in quantity is heavy to carry and cannot always be obtained; 8. A fuel that is not only efficient, but that can be bought anywhere; 9, Moderate price, so as to secure enough orders to make the article wholesale; 10, Inoffensive appearance. The difficulties lie in 5, 8, and 9. An ordinary tricycle weighs, say, 80lb.; this, having to carry machinery, &c., must be stronger, and therefore heavier, say 120lb. To this must be added double-cylinder or rotary engine, copper tube boiler, burners, tank, and at least 1¼ gallon water, circulating pumps, condenser, tank, and 1 gallon fuel; total, say nearly 200lb. This machine must necessarily be heavy to work by foot-power or to push up hills, as if the steam power be sufficient for this purpose, it would be positively dangerous on the level from the excessive speed possible (and very likely to be used). The fuel, however, is the greatest difficulty. Petroleum alone is easily obtainable in little out-of-the-way places, and that material cannot as yet be used on the small scale as a steam getter without both smell and heavy carbon deposit. Spirit which is all that can be desired is not commonly sold, and to be landed in a beautiful country 20 or 30 miles from the nearest town with a 200lb. machine to propel is a prospect certainly awful to contemplate. Finally, as the demand would not be very large, the price to cover all these requirements would be excessive; for a machine to carry one person, very different from the £40 originally talked about. The machine, as made by Sir Thomas Parkyns, was ingenious, and worked perfectly for, say, half a mile, on level ground; then something or other inevitably went wrong, and repairs were needed for a fresh start. In its then state it was an ingenious toy, but not a commercial article. To render it so, much pains was taken, and a lot of money spent, with the result that it became too complicated and liable to disarrangement. In short, the small size made the difficulty. A carriage to take several passengers could doubtless be comparatively easily managed, but I have been compelled long since to reluctantly abandon the idea of a practical steam tricycle.—A. H. BATEMAN, East Greenwich.

[56628.]—**Heliograph.**—I think this will be clear to "Magister Artibus." The heliograph is laid by means of a sighting vane, which is extended a few inches in front of the mirror by means of a jointed rod. To adjust the sighting-vane on a distant point, the signaller places himself in front of the mirror with his back to the distant station, and moves his head and eye until he sees the distant station reflected in the exact centre of the mirror. He then, without moving his head, moves the sighting-vane until the reflection of the sighting spot is brought accurately in line with the centre of the mirror and the reflection of the distant station. The sighting spot is then in a direct line between the distant station and the centre of the mirror, in whatever direction or inclination the latter is placed. The signaller now moves behind the instrument, and directs the reflection of the sun on the vane by moving the mirror vertically or horizontally. The sighting-vane is a piece of white metal on which is marked a sighting spot, which is either a black spot or a cross. A small circle in the exact centre of the mirror is left unsilvered, and consequently cannot reflect the rays of the sun, and this unreflecting circle causes a small disc of shadow to be projected in the centre of the reflected light, which is called the shadow spot. The shadow spot must be made to agree with the sighting spot while the key is depressed, and the light from the mirror will then be thrown on the distant station. As the sun has a continual motion in the heavens, so this shadow spot can only be kept adjusted to the sighting spot by constantly altering the direction of the mirror by the two slow-motion screws. The signaller, while sending a message, must fix his eyes constantly on the vane to see that he is keeping the shadow spot in the same relative position to the sighting spot when the key is released, that whenever he presses down the key the shadow spot should strike the sighting spot. ("Manual of Army Signalling," pp. 11—13). If the sun is behind the signaller, two mirrors have to be used, and the adjustment is made in a somewhat similar manner by moving the second mirror instead of the sighting vane. The second mirror has a sighting spot painted upon it, and is not moved during the course of transmission of a message.—A VOLUNTEER SIGNALLER.

[56650.]—**Lead Burning.**—I do not understand why Mr. Holmes should have troubled himself to state that I am not quite correct about the quality of acid, when my letter on page 287 of the "E.M." distinctly states that the very best sulphuric acid should be used by the young beginner. Of course, brown vitriol can be used, and also other such acids; but there is nothing like giving definite instructions with regard to the acid and zinc used. Mr. Holmes has simply repeated the words of my book delineated on pages 63, 64, 65, &c. He says, start with flat burning, and with 6lb. or 7lb. lead; that will be found on page 63, line 14 from top, right-hand column; and on pages 64 and 65 I have not only told my reader about nailing the lead on a piece of board, but have illustrated the same; and as to the cleaning of the lead, I should think I have spoken of this at least a dozen times. More than this, I can produce plenty of young plumbers who have mastered lead burning without any instruction save and except the reading of my writings in the "E. M." What would Mr. Holmes have us think when he speaks of "using clean zinc free from iron, wire, &c., and free from paint"? Surely he would not expect wire and paint to be mixed up with pure bar zinc, which I always recommend. It would be an easy matter for a young beginner to get wrong if he does not follow the instructions with regard to the class of material, and which I find of the greatest importance to instil into the minds of young beginners, and after the art of lead burning is learnt, with sufficient chemistry for making his gas, the workman can be credited not to break the laws by using inferior materials without being taught to do so in the pages of the "E. M.," and I still think it is too much to expect a second edition of the articles on lead burning within so short a time; more especially as the articles have been printed in book form. With regard to Mr. Holmes recommending "Young Beginner" to renew his acid and water as often as the gas begins to burn dirty, I would ask him if throwing the gas away is the only thing he would do under the circumstance, as I frequently find the gas dirtier at the first half-hour of the machine's work than I do at the finish. Does Mr. Holmes consider that there is nothing to be done but to throw the acid away? I should consider it a great waste throwing the acid away in that manner; and has Mr. Holmes noticed this phenomenon, especially when using the brown acid which he speaks of?—P. J. DAVIES.

[56659.]—**Cutting Ebonite.**—A well-hardened tool, with elbow grease and an oilstone, is, I believe, the only method.—F. M. ROGERS.

[56660.]—**Eclipses of Small Hand of 24h. Clock.**—Multiply $2\frac{14}{23}$min. by the hour past which you wish to time eclipse; $2\frac{14}{23}$min. being the time required by the minute hand to gain on the hour hand the space between any two hours. Example: $2\frac{14}{23} \times 23 = 60$min., minutes past 23 o'clock, at which eclipse takes place.—SCOTCH WORKING MECHANIC.

[56667.]—**Re Drill Chuck.**—By far the best drill chuck for medium and large-sized drills is the Oneida, or Little Giant; it has the most powerful grip, and is very durable indeed. Besides taking in a very large drill, it will also hold a needle. For smaller and lighter work, I think the Invincible drill chuck (a new one) is the best, as it is well made and grips very firmly.—W. BUNDY.

[56678.]—**Hardening Jaws of Chuck.**—Jaws should be well heated to a dull red heat, and then cooled in potash and water. If your correspondent likes to send jaws to me, I will get my men to harden them for him, as it requires some care and experience. I won't charge him anything, of course.—W. BUNDY, Queen Anne Chambers, 62, Holborn Viaduct, London, E.C.

[56679.]—**Supported Beam.**—With all due respect to your correspondents "R. W.," "Hemisus," and "J. S. C.," I beg leave to state that their replies to this query are entirely wrong. The beam has a tendency to break by shearing at every point, unless it is without weight, in which case it would not be supported by the points on which it is supposed to rest.—BACCHUS.

[56682.]—**Struck by Lightning.**—If the pains are rheumatic, a 10-grain dose of salicylate of soda will probably give relief in a few minutes.—F. M. ROGERS, F.C.S.

[56687.]—**Wheel Calculations.**—If I understand the drawing illustrating this query, the handle makes B move in an orbit, the radius of which orbit is same as radius of wheels A and C. If this is so, the replies in last issue are very wide of the mark. Dividing 50 by 23 gives quotient

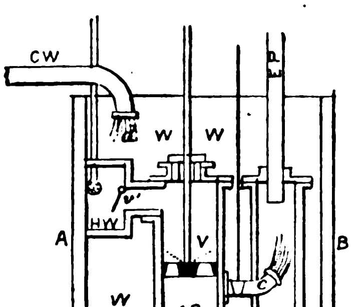
$2\frac{4}{23}$, which is the number of revolutions on its axis B makes for one turn of handle. Now, these axial revolutions would, if B did not move in its orbit, make C revolve once, because $\frac{23 \times 2\frac{4}{23}}{50} = 1$, and the orbital movement of B, would of itself also make C revolve once in the same time and in the same direction, therefore the two movements being combined C will revolve twice for one turn of handle. The size of B is quite immaterial to the result. For example: Suppose B to contain 100 teeth, then $50 \div 100 = \frac{1}{2}$, and $\frac{100 \times \frac{1}{2}}{50} = 1$ revolution of C due to the axial half-revolution of B, which added to the one revolution due to the orbital movement of B, gives, as before, two revolutions of C for one turn of handle.—Scotch Working Mechanic.

[56697.]—**Cutting Glass Bottles.**—I have cut many bottles, &c., of considerable thickness by the following method: Fill the bottle with oil (linseed oil is the best) up to the level of the line where it has to be cut; then immerse slowly into the oil an iron heated nearly to white heat, the glass will separate directly at the level of the oil. The oil can be used again.—E. Gravenstone.

[56697.]—**Cutting Glass Bottles.**—If "Sodium" will fill the glass bottles with cold water to the height he wants them cutting, and get an iron ring about ½in. thick, 1in. broad, and 1in. larger in diameter than the bottles; then get the ring red-hot, and hold it over the bottle at the water line, he will hear the bottle crack. He must then lift off the ring immediately; also the bottle top. I have cut several three-gill spirit bottles in this way to make pint bichromate batteries with success.—G. H. Hepworth, Westgate, Cleckheaton, Yorks.

[56698.]—**Quinine Manufacture.**—Use a wrought-iron coil placed in the oil tank, which should have a manhole cover. Steam can be passed direct from the boiler into the coil. If no regular boiler exists, a small superheater may be employed to raise the temperature of steam obtained from any vessel capable of generating it at a low pressure. If a sketch of tank be sent me, I will show the method employed for passing in the coil through manhole.—F. M. Rogers, F.C.S., 21, Finsbury-pavement.

[56699.]—**Condensing Engine.**—Newcomen was one of the first who condensed the steam behind a piston. In his engine the cylinder was placed immediately above the boiler, from which steam passed directly through a stopcock. As soon as the steam had forced the piston to the top of its stroke, a cock was opened, and cold water admitted into the cylinder to condense the steam that forced the piston up; a vacuum being thus obtained, the pressure of the air, about 15lb. on the square inch, immediately drove down the piston, hence it was called an atmospheric engine. Now, Watt having a similar engine to repair, thought whether he could not prevent the wasteful expenditure of steam, as the great disadvantage of Newcomen's engine was that the cylinder was at one time required to be hot, and at another cold, and that the fresh steam entered a cold, wet cylinder, thereby losing about three-quarters of its power, so he (Watt) set himself to solve the problem of a separate condenser. In this he completely succeeded, and I give a sketch of the condenser and air-pump of his engine. A B is a large casting, within which is placed the condenser C, the air-pump A P, and the hot well H W. V is the piston or bucket of the air-pump with its two valves shut down, but shown by dotted lines as they will appear when the piston V is descending. E P is the exhaust pipe to convey the used steam from the cylinder into the condenser C; C W is a pipe bringing cold water from the pump, *v* the foot valve, *v′* the delivery valve. W W W W is water surrounding the condenser and air-pump to keep the condenser cold. Let us suppose that the steam, having been used, comes from the cylinder through the exhaust pipe E P; the moment it enters the condenser it is met by a scattered jet of cold water from the rose head *c*, and is condensed. The condensed steam and water fall to the bottom of the condenser, and pass, or are drawn, through the foot valve *v*. Then the piston or bucket, V, of the air-pump comes down into the water; the pressure of water opens the two butterfly valves, and the water passes through the valves and so gets above the piston. When the piston is drawn up the two valves are closed by the weight above them, which is next forced or delivered into the hot well H W, through the delivery valve *v′*, from whence part of it is pumped into the boiler, through *d*, a part of the feed pump. As the air-pump ascends a vacuum is formed in A P, the air-pump being in connection with the condenser C, so that the condensing water passes by gravity, &c., through the foot valve *v*, or "follows the bucket." As the air-pump valve descends we see *v* must close, so must *v′*; on the contrary, as it ascends both delivery and foot valve will open. All water contains air more or less. The heat of the steam disengages the air from the condensing water, which would rise through the exhaust-pipe, and prevent the proper escape of steam, besides counteracting its pressure, if not got rid of. The air-pump was therefore added by Watt to his invention of the condenser, to prevent the air from accumulating and obstructing the engine. Hence its name *air* pump, its office being not only to pump out the condensing water, but to keep the condenser free from air. In Morton's ejector condenser the air-pump is done away with; the power in the rush of steam and water is found to be sufficient to carry all the water, air, and uncondensed steam into the hot well at once, without the intervention of an air-pump. That the advantages arising from the diminished reaction on the piston produced by the condensation of the steam are not altogether to be placed to the account of increased moving power will be apparent when it is observed that no inconsiderable part of the power thus gained is absorbed by the cold water pump, the air-pump, and the hot-water pump, all of which are worked by the engine. Neither is the vacuum into which the piston moves so absolute as it might at first appear to be. It is not found practicable to keep the water in the condenser at a temperature lower than, I believe, 100°, and at that temperature steam is evolved which has a pressure of about 1lb. per square inch, which, after all, will still react upon the piston. In comparing, then, the non-condensing and condensing engine, it is apparent that while the latter gives a much greater amount of moving power with the same rate of evaporation, and consequently with the same consumption of fuel, the former is vastly more simple in its mechanism, lighter in its weight, more inexpensive in construction and maintenance, and much more portable. I hope now that with the aid of the sketch you will understand the working of a condensing engine. You ask for description of a surface-condenser, but I am afraid I have taken up too much valuable space already. However, it simply consists in exposing the hot steam to large cold surfaces. Hall's surface condenser consists of an immense number of vertical tubes or pipes placed in a large tank. The steam, after being used in the cylinder, passes through these tubes. Water surrounds these tubes, and is forced through the tank in among the tubes. The cold water enters at the opposite end to that at which the steam enters, thus the hot steam meets the warmer water first and the colder last, by which arrangement the water is made to carry off as much heat as possible. —A. Plucknett.



[56703.]—**Algebraical Problem.**—The number of variations of *n* things taken *r* at a time is—

$$n(n-1)(n-2)\,\ldots\ldots\ldots(n-r+1).$$

And of *n* things taken (*r* − 1 at a time will be—

$$n(n-1)(n-2)\,\ldots\ldots\ldots\ldots(n-r+2).$$

Hence—

$$n-r+1=10$$
$$\text{or, } n-r=9.$$

The number of combinations of *n* things taken *r* together is—

$$\frac{n(n-1)(n-2)\,\ldots\ldots\ldots(n-r+1)}{\underline{|r}}$$

and taken *r* − 1 together—

$$\frac{n(n-1)(n-2)\,\ldots\ldots\ldots\ldots n-r+2}{\underline{|r-1}}$$

Hence—

$$\frac{(n-r+1)\,\underline{|r-1}}{\underline{|r}}=\frac{5}{3}$$

$$\text{or } \frac{n-r+1}{r}=\frac{5}{3}$$

therefore $r = 6$ and $n = 15$.—H. H.

[56705.]—**Potter's Kiln.**—My kiln was a round one, built to burn red and fancy ware, 7ft. to the spring of dome, 14in. brickwork; dome to rise 2ft. single brickwork, with chimney 3ft. high, 9in. flue, with drawing damper to regulate the draught, laying in one brick thick from top of dome, to be built with four fire holes equal distance apart, 9in. wide, 2ft. 9in. high from ground to top of fire hole, the grates 1ft. from ground, with cast-iron doors 9in. square; the kiln to be banded at the spring of dome, and also just under the bottom of the wicket, and close above the fire holes; the wicket to be 18in. wide, and carried up from the level of top of false bottom of kiln to the spring of dome; the kiln to contain a false bottom 3ft. up from the ground to where the wicket commences. The bottom to be built with a space of 1½in. up from where the grate commences all round from the wall of kiln, to allow the fire to circulate freely; the false bottom to be built with a space of about 1in. between each brick to allow for draught, and also holes to be left in the false bottom about 1ft. or 15in. in, to correspond with the fire holes in the kiln walls, the bricks to be gradually brought over the fire holes in the false bottom, so that you finish the bottom of kiln all one nice level, the bricks left about ½in. apart, then 9in. slabs or tiles with 1½in. teits, forming like a low stool, to be built on edge-ways all around the kiln inside, three courses high from top of false bottom, the teits of the slabs to rest against the sides of kiln inside the space between the slabs and that of the false bottom, correspond and carry the heat to the upper part of kiln, and regulate the firing better. Hope Mr. Townley will understand; if not, write to me. The false bottom should be firebricks, or bricks made of clay 1 part and sand 1 part. Also the fire holes should be lined with firebricks.—S. Arlidge.

[56711.]—**Fulcrum.**—The weight of bar will act through its centre of gravity, which will be at middle of bar, so we have 6lb. and 4lb. 5in. apart. Divide the distance apart by the sum of the weights, and multiply quotient by 6 for distance of fulcrum from centre of gravity, or by 4 for distance of fulcrum from 6lb. end, thus $\frac{5}{10} = \frac{1}{2}$in., which multiplied by 4 gives 2in. as distance of fulcrum from 6lb. end.—Scotch Working Mechanic.

[56715.]—**Hydraulic Capstans.**—These can be made in various ways, one of which is a 3-cylinder engine, driving wheel and worm gear.—F. M. Rogers, 21, Finsbury Pavement, E.C.

[56722.]—**Flywheel.**—Weight depends on what engine has to do; for instance, if it drives a fan or centrifugal pump, it may be smaller than if it drives a shaping machine. Say for what purpose it is used, and I will try and help you.—S. Beeching.

[56727.]—**Resistance Coils.**—Ordinary wooden reels, such as are used for cotton, will do very well for the smaller sizes, if previously boiled in melted paraffin. For larger and more accurate coils, to obviate errors through heating, it is better to wind the G.S. wire (covered of course) round a brass tube, which is then inserted in a little brass box, with an ebonite top, the terminals projecting through this top.—S. Bottone.

[56737.]—**Cutting Indiarubber Discs.**—It depends upon the number of discs required, as to the apparatus I should recommend for the purpose; if only a few dozen, a tool like a pair of trammels might be used, one leg being for centre, the other holding the knife. If a large number are required, there should be a surfaced table of hard wood, a disc to press on top of rubber, and an adjustable knife driven by upright spindle and gear, and lever to regulate cut. It is against the rules of "Ours" to mention names of makers; but if "Novice" will look out my address in "Sale" Column, I will give him full information.—S. Beeching.

[56743.]—**L. and N.W.R. Engines.**—The principal dimensions of the "Severe" class are: Driving wheels (four-coupled), 6ft. 6in.; leading wheels, 3ft. 9in.; cylinders, 17in. by 24in. Inside bearings. Weight, 29tons 4cwt. This class of engine was built by Mr. Ramsbottom. The drivers much prefer the ordinary "Precedent" class of express engine to the "Compound" type, which is hardly to be wondered at. The engine 173 "Cornwall" is, or was till lately, stationed at Whitchurch, and worked the traffic between Wellington, Crewe, and Manchester.—H. Bill.

[56745.]—**North-Eastern Engines.**—I am informed that the engines recently built are constructed on much the same general plan as Fletcher's express engines, Newcastle-on-Tyne.—Wm. John Grey, F.C.S., Analytical Chemist.

[56746.]—**A Disagreeable Noise.**—There is, I am afraid, little to be done in this case. I would place under each post of the bed a pad of vulcanised rubber, an inch thick, if you can get it.—Os.

[56746.]—**A Disagreeable Noise.**—In my opinion it is purely a case of conduction of sound, not of air-transmitted sound. No padding of windows would in any way relieve it. The best way is to bed the anvil itself on some elastic body, such as a layer of cork, or sheet rubber. Very probably either a sewer, or water, or gas pipes run under your shop, and across to the house in question. At any rate, an elastic cushion under the anvil will take away the nasty jar complained of—INVICTA.

[56747.]—**Governors.**—To give you all particulars and sizes would need at least a sketch, and that I could not give satisfactorily, unless I saw the whole design of the engine, so that the governor could be arranged to suit it. My own time is much taken up; but if no one else deals with it fairly, I will, on seeing general plan of engine, do my best for you. Boiler: I would refer you to page 221, reply 56463, where you will find a boiler described for an engine a trifle larger than yours. But if you are going to run at 200 a minute with gas-fuel, you will find it none too large. For 200 a minute I would also advise at least 30lb. pressure, or you will do but a very little work with such an engine. Any further details with pleasure, if needed.—INVICTA.

[56750.]—**Gold Plating.**—The best and cheapest way would be to coat your steel with lacquer, coloured with some yellow dye. They must, of course, be polished first. They can be gilt; but should be previously coppered, and you will be astonished how cheaply this can be done if you have a quantity. The best finish for steel or iron goods is nickel plating.—OS.

[56750.]—**Gold Plating.**—To a solution of muriate of gold add nearly as much sulphuric ether. The ether reduces the gold to a metallic state, and keeps it in solution, while the muriatic acid separates, deprived of its gold, and forms a distinct fluid. Then make your steelwork bright and free from any oily substance, put the steel into the ether, which speedily evaporates, depositing a coat of gold on the metal by dint of the attraction between them. After the steel has been immersed it should be dipped in cold water, and then burnish it, which strengthens its adhesion, and finally polish with rottenstone and rouge. Figures, flowers, and different devices can be drawn on the steel with very good effect by using a pen dipped in the ether. —JIM.

[56755.]—**Magnesia Firebricks.**—I think this query is identical in substance with No. 56494, "Soapstone Firebricks," p. 200, about which information has been asked from America.—ESSAR.

[56756.]—**Electro-Plating.**—As an amateur, I never considered pewter worth plating, although, as a commercial industry, it is largely done. Have you tried dipping them in a weak solution of nitrate of mercury? The coating of silver must be very thin, as it will then be less likely to strip.—OS.

[56757.]—**Steam Expansion.**—The height of a column of water equal to a pressure of 60lb. per square inch is $\frac{60 \times 144}{62 \cdot 5} = 119 \cdot 17$ft. and $v^2 = 2gh$, $\therefore 2g = 64 \cdot 4$, and as the volume of steam to that of water at 60lb. pressure is 437 to 1, $\therefore v = \sqrt{119 \cdot 17 \times 64 \cdot 4 \times 437} = 1831 \cdot 3$, being the velocity of steam per feet per second into a vacuum.—R. N.

[56763.]—**Water Analysis.**—In the analysis of water, it is usual to estimate each base and acid separately, and then to calculate the amounts of the various salts which are presumed to exist in the water. The querist will find an example fully worked out in Fresenius' book on quantitative analysis. 70cc. is much too small a quantity of water for the purpose.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56764.]—**Tempering Carpenters' Tools.**—This is such a general question, and the back numbers and vols. contain so much information on the subject, it would be well for the querist to search the indices in the first place, and if unsuccessful, to state what his difficulty is.—OS.

[56764.]—**Tempering Carpenters' Tools.**—"Tool Worker" asks for a good book which explains the right way to temper carpenters' tools. In Lock's "Workshop Receipts" (third series) of which Messrs. Spon are the publishers, he should find all he wants. The book contains much valuable information on this subject, and the frontispiece is a colour scale for tempering all kinds of tools.—BOBADIL.

[56764.]—**Tempering Tools, &c.**—The best information yet published on this and other workshop matters is given in a book called the "Works' Manager's Handbook for Engineers," by Hutton, published by Crosby Lockwood and Co., Stationers' Hall-court, Ludgate-hill, London. A very complete and practical work, different to all other books in this line.—A. COLE.

[56765.]—**Polish for Walnut Table.**—Eau de Cologne is made with spirit of wine, and has taken off the polish. It might perhaps be revived, to a certain extent, by careful rubbing with a mixture of linseed oil and methylated spirit; but the only radical cure is to have it repolished.—OS.

[56770.]—**Putty.**—Linseed oil and whiting make the best of putty; but before use it does require to be well worked with the hands; if it will not stick, it is probably too hard (too much whiting). A pound of putty can be bought for about twopence, and it must then be worked till quite soft; it will not hurt the hands, rather improve them than otherwise, and hot water and soap will remove the last traces.—OS.

[56775.]—**Small Gas-Engine.**—To "INVICTA."—I am very glad that at least one subscriber has assisted me to ventilate this matter, and I trust more will follow. Replying to your first suggestion, I certainly agree with you on the point you raise; why all should not participate seems to me depreciating the value of concession. At one time it was suggested that the decision of the Editor should be taken, and to be final, as to who were or were not, in his judgment, amateurs or who should participate. Now, personally, I should like the idea of a referee such as our mutual friend, the Editor. But would he, without considerable trouble, be able to say yes or no? Of course, if we could persuade him to act as our arbitrator in the matter, I should feel more than satisfied. Now, supposing that it was arranged thuswise: that the Editor (assuming him to be so good as to undertake the office) should say—(1) If the applicant was entitled to be regarded as a subscriber; and also to fix, if needs be, the minimum time he should have so been a subscriber. (2) Then I would suggest that it be put to the Editor to decide a more important question—viz., whether or not the applicant was, in his opinion, in possession of such ample means that he could afford to buy a gas or other engine at full price, and therefore should, or should not, be entitled to indirectly get an engine at the cost of making only. These are two points which, I fancy, are of value, and I think that they are not altogether unreasonable. It might be even arranged on some coupon system. But, doubtless, this will evoke further remarks of value. Now, I know the only dangerous point on the other side, and it is this: that no patentee, or company, or manufacturer would be likely to throw open or give use to any but those who they are assured would not be cash buyers otherwise. And hence my wish that such a question be referred to and definitely settled by the Editor, say. Further still, persons in trade, and wishing to use the engine for daily trade purposes, are hardly on the same basis as an amateur requiring the engine for his own private use, because a tradesman can, as a rule, afford to buy an engine in the usual way. I don't want to say more on this, as it may perhaps raise difficulties; but what I do wish is to help amateur mechanics, or those taking an interest in mechanics, and who would therefore hail an engine with delight. Now, on the last paragraph of our friend "Theo's" communication there is no doubt that it is quite possible to make an engine on some already expired patent; but the only one of any real use is that of Lenoir, of 1860 and 1862. His was the first engine of real practical use, in my opinion. Now the construction of such an engine would be far beyond the usual amateur, as the boring and pattern-making is very complicated. I have had placed in my hands for perusal a quantity of information in the shape of letters from the actual constructor of the Lenoir gas-engine in England, and I must say, that although I respect it as the first practical engine, yet very little seems to have sufficed to put it out of order. As I am not sure, speaking from memory, whether Mr. Wenham's engine was before the Lenoir, I mention this, as in that case not desiring to in any way ignore the motor produced by the former gentleman. But both Mr. Wenham's engine, I am told, and the Lenoir, I know, make a good deal of noise in working, whilst the motor I want to get into the hands of my brother amateurs runs as silently and steadily as the Otto; and I want to get for the general good the best to be got. Besides the Lenoir there are lots of expired patents; but I do not see a single one that would be suitable. Not only so, but I differ from "Theo" on the point of gas consumption. Surely it is worth some little trouble to get an engine burning, say, only three farthings or a pennyworth of gas an hour, rather than accept one burning say, 4d., with perhaps lots of bump and other noises. And it is the silent running of a steam-engine that is one of its points for an amateur; therefore our gas-engine ought to be equally silent. Many of us want to place them on perhaps upper floors, and absence of bump and noise and vibration are then indispensable. My reply has already reached such an inordinate length, that I cannot now say more than that I trust we shall hear more on the matter.—INVICTA.

[We could accept no such responsibility as is suggested. Moreover, this discussion is fast bordering on an advertisement, and any such cooperation as is sought must be sought in the ordinary way.—ED.]

[56776.]—**Electro-Motors.**—To MR. BOTTONE.—I should strongly advise you to address a query to Mr. H. Jones, through the medium of our paper, on this subject. His experience with these motors is far greater than mine, and therefore more likely to be serviceable to you.—S. BOTTONE.

[56777.]—**Putty.**—The way we made it when I was an apprentice was: the whiting was stoved to dry it, when cool rubbed through a fine sieve, mixed with raw linseed oil on a stone slab until stiff, left for a day or two to sweat, as we called it, then worked up again with dry whiting till stiff again; treated this way about every couple of days for about a fortnight, then you will have good putty—the kind you will not be able to buy at the oil and colour shops, as it is "mill" putty that is sold, made up of all sorts of "stuff."—J. A. P.

[56778.]—**Circle.**—Let $a$ $b$ be the speeds of A. and B. respectively, and $c$ the length of the circumference of the circle. Then, when they meet, A. has gone a distance $\frac{ac}{a+b}$, and when A. again overtakes B. he has gone a distance $c + \frac{2ac}{a+b}$. Therefore, we have $b\left(c + \frac{2ac}{a+b}\right) = ac$; whence $a : b :: 1 + \sqrt{2} : 1$.—EAST ANGLIAN.

[56778.]—**Circle.**—Let C = the circumference of the circle in feet. Let $a$ and $b$ represent the number of feet per minute that A. and B. can run. Since A. and B. can run $(a + b)$ feet in one minute, this will complete the circle in $\frac{C}{a+b}$ minutes, and A will have run $\frac{aC}{a+b}$ feet, and B $\frac{bC}{a+b}$ feet. Now, by the conditions of the question if A. reverses his direction he will overtake B. after traversing $\left(C + \frac{aC}{a+b}\right)$ feet; but in the time A. runs this distance, B. in order to meet him at the starting point, must have run over the distance formerly traversed by A., or $\frac{aC}{a+b}$ feet.

$$\text{Therefore, } \left(C + \frac{aC}{a+b}\right) \div a = \frac{aC}{a+b} \div b$$

$$\text{or, } \frac{C}{a} + \frac{C}{a+b} = \frac{aC}{b(a+b)}$$

$$\therefore\ b(a+b) + ab = a^2$$

$$\therefore\ a^2 + 2ab + b^2 = 2a^2$$

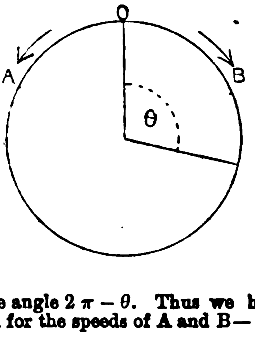
$$\therefore\ a + b = a\sqrt{2}$$

$$\therefore\ b = a(\sqrt{2} - 1)$$

$$\therefore\ a : b :: 1 : \sqrt{2} - 1.$$

—J. C. KELLY.

[56778.]—**Circle.**—Let O be the starting point on the circle, and $\theta$ the angle which B has moved through when B meets A. Then A has moved



through the angle $2\pi - \theta$. Thus we have, if A and B stand for the speeds of A and B—

$$\frac{A}{B} = \frac{2\pi - \theta}{\theta} \qquad (1)$$

Again by the question—

$$\frac{A}{B} = \frac{2\pi + (2\pi - \theta)}{2\pi - \theta} \qquad (2)$$

These two equations give the value of $\theta$ by a quadratic as—

$$\theta = \pi(2 \pm \sqrt{2}).$$

Since A is supposed greater than B, we take the minus sign. So that we have from (1)—

$$\frac{A}{B} = \frac{2\pi - \pi(2 - \sqrt{2})}{\pi(2 - \sqrt{2})}$$

$$= \frac{\pi\sqrt{2}}{\pi(2 - \sqrt{2})} = \frac{\sqrt{2}}{2 - \sqrt{2}}$$

$$= \frac{1}{\sqrt{2} - 1} \text{ Ans.}$$

—L. EDMUNDS.

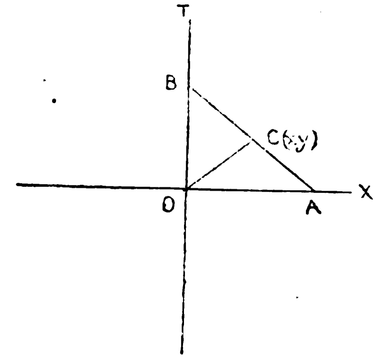
[56779.]—**Problem.**—Let $2a$ be the length of each of the straight lines, so that $a$ is the distance of their extremities from the point of intersection. Take this point as origin, and the straight lines as axes, then the points $(h, 0)$, and $(0, \sqrt{a^2 - h^2})$ are contemporary positions of A and B; and the co-ordinates of C at the same time are given by

$$x = \frac{h}{2} \qquad y = \frac{1}{2}\sqrt{a^2 - h^2}.$$

Therefore, eliminating $h$, we have for the locus of

C $4(x^2 + y^2) = a^2$, and this represents a circle whose centre is at the origin, and whose radius is $\frac{a}{2}$.—East Anglian.

[56779.]—**Problem.**—Let $x_1 y$ be the co-ordinates of the point $c$, and let $x_1' y'$ be the lengths O A, O B.



Thus we have—

$$x'^2 + y'^2 = a^2$$

where $a$ is half the traverse. Now $2x = x'$, and $2y = y'$ by the figure.

$$\therefore 4x^2 + 4y^2 = a^2$$

and—
$$x^2 + y^2 = \left(\frac{a}{2}\right)^2.$$

Hence C describes a circle with O as centre and radius equal to half the traverse.—L. Edmunds.

[56780.]—**Camping Stoves.**—Certainly you will find the methylated spirit stove far superior to any oil burning stove in any open boat or small yacht. I speak from experience of many sorts. The spirit stove heats much quicker than the oil. The burners want no attention, and, above all, your utensils require no outside cleaning after use. There is no unpleasant smell even in a small cabin. The fuel is certainly more costly, but you require less of it. There is this drawback—that you cannot replenish your stock in out-of-the-way villages. You are right in having two stoves, and I include two kettles in my canteen. If you want a lamp, have one with a duplex burner, burning colza oil; but I have long discarded mine altogether, as it only makes the boat a rendezvous for all the insects within sight.—W. M. J. L.

[56780.]—**Camping Stoves.**—Having been on several camping-out trips I strongly recommend a good paraffin stove as the most all-round useful (either Rippingille's or Wright and Butler's); my last was of the latter make, and for two years since it has done good service at home in the summer, when fires can be dispensed with. Our last trip had three passengers, and a small-size W. and B. square stove served us very well; we also had a very small spirit stove as a supernumerary, such as to boil an egg. For compactness in packing for transit it would be easy to make some of the pans and kettle fit one into the other. I got a tinman once to make for me a small "cuisine" for spirit, with pan (for frying), saucepan, and kettle, the lamp fitted into the kettle, these into saucepan with frying-pan outside, for one person's use; but the "kit" was coveted by a cousin-canoeist, and I had not much practical trial of it. I hope you will only have as much pleasure out of your boating and camping-out trip as I have had on the three or four which I have taken.—Cæsar.

[56782.]—**Marking Bone or Ivory.**—I have seen toothbrushes marked with ordinary steel punches, the punches being blacked in a smoky flame, care being taken not to draw the temper.—Os.

[56783.]—**Steam Brake.**—I recollect some years ago riding on the footplate of an engine, I think on the Paris, Lyons, and Mediterranean Railway fitted with this brake. It certainly seemed to answer well, and I understood that a good number of engines were so fitted. If I recollect aright, one drawback was that so many points needed attention, that perhaps for that reason it was not generally used. For instance, the regulator had to be partly opened, I think, and a valve closed so that air was drawn in from outside the smokebox, whilst the water-jet had to be turned on. Then, again, I recollect that at one place the brake was nearly useless. As the full power must be applied, or nothing, the wheels slipped so much on a greasy piece of road, that we had to resort to the tender brakes. In these days of continuous brakes, such a retarding agent is not as simple as a steam brake on the drivers. I trust some other contributor who has seen the system at work will also reply.—Invicta.

[56786.]—**Mechanics.**—"Dumbuck" does not make it clear whether the force, P, is to be applied to an upper corner, or to the middle of an upper edge of his cube of stone. However, as there will be no tilting of the cube in either case, this makes no difference whatever. His question is—At what inclination to the horizon must the force act, which is dragging the mass along the level floor, in order that it may be the least force sufficient for the purpose? The answer is: The required inclination, or angle, is that whose tangent is $k$, the coefficient of friction, or the ratio of the friction to the pressure of the mass moved. To prove this—When a force, P, is pulling at the mass with an upward inclination, $\theta$, the pressure of the mass on the floor is its weight, W, *minus* the lifting tendency of the upward-inclined P; that is $W - P \sin. \theta$. But the resistance of the friction is this pressure multiplied by the coefficient of friction—that is $(W - P. \sin. \theta)\, k$; the resistance is also $P. \cos. \theta$. Equating these, a slight transposition gives us $P\,(k \sin. \theta + \cos. \theta) = W\,k$ (equation A). Now that P may be a mininum, as desired, $k \sin. \theta + \cos. \theta$, must be a maximum; therefore its differential $(k \cos. \theta - \sin. \theta)\, d\,\theta$, must be zero; whence $k \cos. \theta = \sin. \theta$, and $k = \tan. \theta$; or the required angle is that whose tan. is $k$. Now, expressing $\sin. \theta$ and $\cos. \theta$ in terms of $k$, we easily get from A, $P = W \sin. \theta$. In the proposed case of stone moving on stone, $k$ is just about ·5, as a fair average value; and therefore $\theta$, the angle required, is the angle whose tan. is ·5—*i.e.*, 26½° very nearly; and P the force required, is W sin. 26½°, or 447lb. nearly (W being 1,000). For wood on stone, $k$ would be about ·42, and $\theta$ about 23°, and P about 387lb.—Dubliniensis.

[56787.]—**Drilling Rough Plate-Glass.**—If large holes are required, use bits of copper tube notched on edge and a little fine emery and oil. If small holes, an ordinary drill kept moist with water—or, if you like it better, turpentine—will do the work.—Essar.

[56787.]—**Drilling Rough Plate-Glass.**—Small holes in plate-glass, rough or otherwise, can be drilled with a drill of the ordinary diamond shape, tempered in mercury, and lubricated with spirits of turpentine during work. Of course a diamond-tipped drill is preferable, but it is an expensive tool. When in the glass working profession on the Continent, I always used for large holes a drill formed of a copper tube of the diameter of the hole desired, with the outer edge bevelled. When in use it has to be wetted with emery and water; it must be mounted in such a fashion that emery and water can also be put inside. This method is the safest, as there is no danger of cracking the glass. The drills must be always driven at a high speed, with little pressure on the glass.—E. Gravenstone.

[56788.]—**Agglomerate Battery.**—The blocks are probably exhausted, and if so, it would be better to purchase new ones than attempt to repair the old ones. Or the carbon terminals may be corroded, and so prevent the passage of the current. Scrape off the corrosion (if any) with a file or a knife.—Bobadil.

[56789.]—**Klinkerfues' Barometer.**—If you have not another Klinkerfues handy to compare with, you may set your instrument by an ordinary barometer. Divide your scale by ink dots into three inches, 28 to 31, and you can easily get an approximate position. It will not matter that this is not exact, for the great value of the Klinkerfues weather-glass is not its permanent record, but the forecast afforded by the index change from a known position to another within a certain period of time. The range of the Klinkerfues is more extensive than that of the ordinary barometer, so that the two must not be expected to keep together.—J. R. C.

# UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

# QUERIES.

[56794.]—**Storage Batteries.**—Will any of your electrical correspondents tell me how to make storage batteries with lead plates, for storing electricity, for lighting purposes, giving, if possible, sketch of same with connections, size of plates required, and number of cells for 30 20-c.p. lamps? Would the lead that comes on tea-chests do for same, as I have a large quantity by me?—An Old Subscriber, Walsall.

[56795.]—**To Mr. Wimshurst.**—Would Mr. Wimshurst kindly explain the inductive action carried on between the revolving discs of his influence machine? Also what action is carried on by the so-called neutralising rods and brushes, upon the brass sectors; and if not trespassing too far, could not a spark, and therefore a charge, be obtained if the neutralising rods were connected to an insulated prime conductor, the same being at one end of the frame work?—W. B.

[56796.]—**Boiler Query.**—To "Invicta."—I have a wrought-welded iron boiler, 9in. square, 20in. high, ⅜in. thick plate, by me, and as I want to convert the same into a steam boiler, I shall be glad if "Invicta" will kindly give me the pressure it is safe to work it at, also the size of bore of cylinder that it is capable of working. I may mention that it was made for a high-pressure range boiler, and that it is new. Also I should be glad if he would give me the diameter of the safety-valve, and the length of lever?—R. Hearn.

[56797.]—**Lamp Wick.**—Is there such a thing as an incombustible wick? Would asbestos answer?—Backwoodsman.

[56798.]—**Filter.**—Can any of "ours" kindly assist me to ascertain the size of filter that would be required to filter a stream of water, running in a flume, that has only a fall of 4in. in 400ft.? Size of flume, 10in. by 12in. A constant flow of water is required for five months, during which time the supply must not cease for more than a few minutes. At lower end of flume the water is a little over one third the depth of flume, or nearly 4in. deep by 12 wide—something reliable and inexpensive is wanted. A fall of ten feet at lower end of flume can be utilised for filter if required.—Backwoodsman.

[56799.]—**Sand for Cores.**—Will some reader kindly tell me what kind of sand to use for cores for brass bushes, &c.? Being in the country, I have no opportunity of buying right sort; but thought, perhaps, as there is plenty of sand about, I might, with a little advice, mix some that will answer.—G. G.

[56800.]—**Pianoforte Tuning Hammer.**—Would any of your musical correspondents kindly let me know the best kind of pianoforte tuning hammer now used?—Vanduara.

[56801.]—**Organ.**—A reader of the English Mechanic will be glad to know what is the smallest quantity of water that could be used to blow an organ having three rows of keys, the fall required, and the apparatus to be used under the circumstances?—A. H. F.

[56802.]—**Shunts.**—With the shunts $\frac{1}{999}$, $\frac{1}{99}$, $\frac{1}{9}$, compare the currents in the galvanometer when any two of the shunts, and when all three, are in circuit together?—K. L. M.

[56803.]—**Electrical Calculations and Measurements.**—I hope Mr. Wright, of S. Hampstead, will give us a further instalment of his interesting formulæ. I see he promises to do this at the end of his letter on page 429, Vol. XXXIV., but I have looked for it in vain.—Glatton.

[56804.]—**Fifteen-Lighter Dynamo.**—Will Mr. W. H. Eaves kindly give me dimensions of armature, armature rings, field-magnets, &c., and quantity and size of wire for constructing a dynamo, similar to the one he is at present describing in "Ours," but to light only 15 lamps instead of 30? I should also like to know resistance of wire on armature and field-magnets, also number of volts and ampères the machine will give at the proper speed, and number of extra lamps it will light for a short time, without heating?—Electricity.

[56805.]—**Torrigelli Barometer.**—Can anyone favour me with the letterpress of the Torrigelli dial, together with the respective tenths or hundredths at which each variation should be placed?—R. Hannen.

[56806.]—**Foci of Lenses.**—Will some of "ours" kindly tell me how to find the focus of any magnifying glass? Are concave do., and achromatic, found in the same way? How are achromatic lenses separated, and what kind of cement is used to join them?—Ignorant.

[56807.]—**Buttons and Buttonholes.—A Hint to the Inventive.**—The button has not yet been invented, and that plague of life still afflicts us. The truth is, inventors are on the wrong track; what we want is a buttonhole, not a button. We cut a hole to hold the button, and then have to fill up the hole with the end of the finger, and so prevent the passage of the button; with what result to the temper is too well known.—Verb Sap.

[56808.]—**Alcohol.**—Can any reader of "ours" kindly give me a rough test for the proportions in a mixture of alcohol and water?—Chemicus.

[56809.]—**Dynamo for Arc Lights.**—To Mr. W. H. Eaves.—Will you kindly say what amount of wire should be wound on an armature, similar to that of your 30-lighter, but 12in. external diameter, and 12in. long? Also size and quantity of wire for F.M.? The machine is to run two arc lamps. What will be the probable strength of each light?—E. K. S.

[56810.]—**Stamp Duty.**—Will Mr. Wetherfield kindly say if an account or poor rate paid by cheque and indorsed paid by cheque, is legal, without adding a stamp to such receipt or rate? Is it absolutely necessary to use two stamps for one transaction, one on cheque and one on receipt?—J. C.

[56811.]—**Surface Condenser.**—To "Invicta" and Others.—I propose to fit up a low-pressure engine, not over 2lb. steam pressure, and use surface condenser. Will you please describe best form and size of surface-condenser for ½-h.p., amount of cold water per hour, and size of tank in which condenser is placed? It will be supplied from rainwater cistern. Also give size of engine cylinder, and air-pump working at same speed as engine? Your full answer will greatly oblige—SAFE MOTOR.

[56812.]—**Terrestrial Telescope.**—Having one of these of 1¼in. aperture, the flint glass of the achro. o.g. of which has become broken by accident, will some friend kindly say if I could get a new flint glass fitted to it, and how I had better proceed to that end?—C. BORER.

[56813.]—**Fracture of Water Gauge Tube.**—If a boiler attendant unwittingly cleans his water gauge glass (interior) with a piece of cotton waste on a piece of iron wire, that glass tube will assuredly break as soon as steam is up. Why? Also, as an experiment I have laid very carefully up on a shelf, out of harm's way, a glass (gauge) tube, and as carefully inserted a piece of iron wire, without touching the glass, and withdrawn it again, and in nine cases out of ten the glass, though remaining untouched, will fly into several pieces, generally with a longitudinal slit and several transverse ones. Why?—C. BORER.

[56814.]—**Hot Foods in Hot Climates.**—Why are curries, &c., partaken of by people in hot climates? What physiological effect have they to make them so sought after and consumed?—C. BORER.

[56815.]—**Tank.**—Will some of my brother readers answer the following and oblige? Given a tank of 3ft. deep filled with water, the level of which is 10ft. above point of discharge; required to know whether tank would be emptied quicker by a 1¼in. outlet pipe in bottom, or by a siphon, same size, starting near bottom passing up to water level and then down through bottom tank as before? Discharge to be started by a valve in both cases.—PLUMBUM.

[56816.]—**Tables of the Planet Venus.**—Will "A Fellow of the Royal Astronomical Society" kindly say which are the latest and most accurate tables of the planet Venus, containing especially the equation of the centre for each degree of the planet's orbit?—J. H. T.

[56817.]—**To Mr. Wenham.**—Would Mr. Wenham kindly publish the way Andrew Muir's link was fitted on to the slide rest, so that the screw nut could be shifted on to different places on the guide screw of a screw-cutting lathe, and how the nut was lifted out of gear?—WM. JAS. BROWN.

[56818.]—**Spherical Aberration.**—In large object-glasses of telescopes in which the crown and the flint glass lenses are separated, does the alteration of the distance between them, which is intended to correct the chromatism, also effect any change in the spherical aberration?—D. T. R.

[56819.]—**Pickle for Brass.**—I should be obliged to any practical man who would say what pickle or liquid dirty brass ornaments are dipped into for the purpose of brightening them, or the process they have to pass through previous to lacquering?—J. H. D.

[56820.]—**Commutator.**—I am manufacturing a sparking coil, primary, two turns No. 18 silk-covered copper wire; secondary, ½lb. No. 40 silk covered wire. Is a commutator necessary for the above, if so, what is its use? The secondary is put on in eight divisions; is this the right form and make up for the coil to give a 1in. spark with three 1-quart bichromate cells? I hope that some of our brother readers will favour me with a reply.—B. JACOBS.

[56821.]—**Grass Seed.**—Can some one give me the name of a treatise on methods of cleaning and separating grass seeds, if such exists, treating the subject both theoretically and practically?—SAAT.

[56822.]—**Small Dynamo.**—To MR. S. BOTTONE.—Having finished a small dynamo of the type described by you in No. 1,007 of the "E.M." Will you tell me the best size and quantity of wire for it? The armature is 5in. external and 5⅛in. internal diameter; 2½in. broad, with sixteen cogs; the spaces for wire are 2½in. long by ⅜in. broad by ⅜in. deep. The electro-magnets 7in. long, by 1⅜in. in diameter; the electro-magnets are wrought iron, and screwed into the pole pieces.—BON BON.

[56823.]—**Steam.**—Will any reader show me how to get the cubic inches of steam in the cylinder, and the quantity of water, in cubic inches, to condense the above with? The steam cylinder is 32in. diameter, 6ft. stroke, pressure on piston 35lb., cuts off at 2·10 the stroke, diameter of air-pump 22in., size of injector pipe 5in.—YOUNG ENGINEER.

[56824.]—**Watch Work.**—Would any reader kindly inform me how to fasten ruby pin in roller?—and oblige—T. W.

[56825.]—**Mechanical Questions.**—Will any of the readers of "Ours" oblige by working out the answers to the following two questions in Applied Mechanics and they will oblige a student? 1st, A beam of fir, supported at each end, is inclined at an angle of 60deg. to the horizon, and is loaded at the centre of its length with a weight of 1 ton. The length of the beam is 10ft. and its breadth is 2in. Find its depth, the breaking load on the centre of a beam 1ft. long, 1in. broad, and 1in. deep, and supported at the ends in a horizontal position, being 450lb.—STUDENT.

[56826.]—**Loss of Power.**—A weight of ½ ton is moved on well lubricated cast-iron plane surfaces, such as the V grooves in a planing machine, and moves to and fro through 4ft. making two double strokes per minute. Estimate in-foot pounds the loss of work in moving this mass and bringing it to rest, and in overcoming the friction of the rubbing surfaces,—STUDENT.

[56827.]—**Large and Small Chilled Rolls.**—Will any reader of the ENGLISH MECHANIC oblige one doubtful with the proportions of metals for the above, to give chill from 1in. to 2in., and if it is right to set chill moulds aslant in casting?—A CONSTANT READER.

[56828.]—**Hot Water Pipes.**—You have an ordinary flow and return pipe running along a landing one above the other, a certain distance above the boards, i.e., not under the floor. Now can you dip these pipes in order to get past a doorway that has no step, provided the relative position is the same where they go under the boards, past the door, i.e., one above the other?—S. F.

[56829.]—**Paraffin Lamps.**—To MR. POSTLETHWAITE.—I have read your letter *re* Paraffin Oil Lamps in the ENGLISH MECHANIC, No. 24266, with much interest. Soon after the Silber lamp came out, I tested it against the Duplex and Capt. Doty's burner. I regret to say I have since lost the notes I then made, but distinctly remember that I then considered I obtained more light from the Silber than either of the others for the same money, and that at that time the Silber cost ½d. per hour, the oil, I think, costing 2s. 6d. per gallon. My object in troubling you with this letter is to beg that you will give us the results of your experiments, and a description of the lamp of 22c.p., that you can burn continuously for 132 hours. I also use a magic-lantern with oxycalcium, and Newton three-wick petroleum lamp, in which, by the way, I always think there must be loss of light from the fact of the three wicks being all set "edge on."—E. E. MONTFORD.

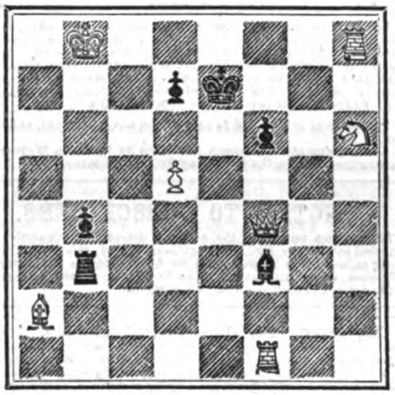
[56830.]—**Pianoforte Making.**—To MR. DAVIES.—In Vol. XXVII. you wrote some articles on "How to Make a Pianoforte." Will you kindly answer one or two queries? In article II. you describe the bellying of the soundboard, but there is nothing said about the back of ditto. I suppose there is a back, or is not one wanted? Then, again, is there nothing besides the traverse bars to support the soundboard, and do they (the bars) rest on the bracings at the ends or not? Surely the thin soundboard would not bear the downward pressure of all the strings. I cannot get the first article, as the number is out of print; so would you give me the sizes of the framework, and the manner in which put together? Is there any bracing required between the two outside bracings?—A PIANOFORTE.

## CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

PROBLEM DCCCCXLIII.—PATHFINDER.

*Black.*



*White.* [7+6

White to play and mate in two moves.

SOLUTION TO 941.

| *White.* | *Black.* |
|---|---|
| 1. B-K B 5 | 1. Anything. |
| 2. Q, R B or Kt mates. | |

(Eight variations.)

NOTICES TO CORRESPONDENTS.

CORRECT solutions to 940 by J. A. Miles (very fine problem), G. T. Stringfellow, T. L. Robins, A. A. E. Lecluse (very fine), F. O'N. H., I. H. (but main variation 1. K-K 2, not given).

To 941 by J. A. Miles (a block of the old type, and key move very stale), G. T. Stringfellow, Streetgate, A. W. Orr, A. A. Lecluse (ingenious), Rev. W. Anderson (Old Romney), R. F. Sunderland, I. H., J. E. Piper (the best that has appeared), R. A. Bennett, S. L. Chivers.

To 942 by E. S. (admirable) and Rev. W. Anderson (Old Romney).

I. H.—Of course you start at a disadvantage; but it is impossible to foresee the result yet, as there are several problems to follow, therefore we recommend you by all means to compete.

F. A. VINCENT.—You have probably noticed that the problem is quite correct.

J. M. (Ealing), AND F. B. WEBB.—You have overlooked in 941, that if 1. Q takes P, Kt discs. (ch).

C. W. Last.—Game received with thanks.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

## ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, June 10th, and unacknowledged elsewhere:—

MORRIS COHEN.—W. Ryan, C.E.—Bausch and Lomb Optical Co.—A. J. Herbert.—Centaur Cycle Co.—W. Munro.—J. Parnell.—J. M. Chadwick.—R. T. Lewis.—C. Richardson.—G. M. Heaven.—W. Jesse Lovett.—Tiller.—D. Booth.—Penwith.—Egroeg.—Num Skull.—Isaac W. Ward.—F. A. M.—Wild Rushes.—Alexander.—Rosicrucian.—W. Bundy.—W. R. A.—G. Bouron.—W. H. O.—Rev. Jas. Pearson.—Bouclier Ignorant.—H. Cambourne.—E. R. H.—T. H. and S.—Eyepiece.—T. H. L.—A Fellow of the Royal Astronomical Society.—Meniscus.

A CONSTANT READER. (Steel such as is used for making files or drills will answer. In what way does your steel fail? Do you use a lubricant, such as water, when boring?)—PLODDER. (Joy's valve-gear has been explained many times in our columns. You will find an illustration of it as applied to a locomotive in No. 954.)—C. REVELL. (You should have stated whether you meant the mercurial process used for looking glasses, or the silver process for telescope mirrors. You will find the latter described in Vol. XXXIV., pp. 22, 38, 91, 111, 187, 285, 308, 463, &c.)—OUBA JUTHOS. (Query is of too limited interest. There is nothing to prevent you adopting chemistry as a profession; but if you cannot attend a series of laboratory lectures you have a very small chance of obtaining sufficient knowledge to secure an appointment as chemist.)—F. J. L. (Try benzine. Turpentine is usually effective.)—ALFRED SEDGLEY. (For general description of the gyroscope, see p. 225, No. 946. See also the indices. Your query should have asked for specific information, as it is impossible to repeat general descriptions in order to possibly enable a querist to discover a defect.)—VALERIA. (For lacquering brasswork, see the indices. It is difficult work, to be learned only by practice. The work must be as hot as can be held, or rather hotter, and the brush should not be taken over the same place twice. Recipes for making lacquer have been frequently given; but it is cheaper and better to buy.)—J. E. PATTERSON. (It is a male specimen of the cockchafer or May beetle (Melolontha vulgaris), which lives for about a week. The female burrows into the earth and deposits her eggs, which soon hatch into little white maggots, that commence at once an attack upon the roots of grass, wheat, potatoes, and almost anything vegetable, which lasts for three years, when the grubs have grown to a considerable size, and almost burst their skins with fat. At the end of three years the grubs cease eating, and commence the metamorphosis, issuing about the end of May or beginning of June in perfect form as a beetle, like that sent. In that stage they do a great deal of damage to trees, and are a great nuisance in the evening, flying about here and there, and not unfrequently catching the pedestrian a smart blow on the face. At present, no method of dealing with the grubs is known, as they bury themselves deep enough to keep out of the reach of any insecticide. Rooks, however, dig them up, and follow the plough in search of them. The beetles can, however, be destroyed by placing a cloth under trees infested with them and shaking the branches, emptying the beetles into boiling hot water. That must be done in the daytime when they are reposing on the undersides of the leaves.)—ARTIST. (It is best prepared by heating nitrate of ammonia. See a textbook on chemistry, or the indices of back volumes. It is useful as an anæsthetic, but should not be played with.)—H. B. (The address is—Secretary, Science and Art Department, South Kensington.)—BIRMINGHAM. (The instrument is worked by a spring in the usual manner. The coin simply releases the detent by falling on a lever, and is itself tested by the size of the slot and by the fact that it moves the lever, to do which it must be up to weight.)—LUMP. (You must let a medical man examine it.)—IGNORANT. (It seems simple enough, and the defects are probably only in the surfaces in contact. The falling arm is, we presume, insulated.)—NOTTINGHAM. (It is known as Lucas's paradox, and you will find all about it in Vol. XXVI. with illustrations. See p. 532, that volume, for instance. If you try again, you will find that the fitting is not accurate, and that a space equal to one square inch is uncovered.)—ASTON ON RIBBLE. (It is indiarubber mixed with sulphur and vulcanised under the influences of heat and pressure. Steam supplies both heat and pressure, as in the dentist's vulcaniser.)—F. HASKE. (Yes, the broad gauge was in use on the Metropolitan Railway when it opened. The line was laid with both gauges.)—G. MITCHELL. (See the article on p. 292. Any reduction of pressure puts all the brakes on. If a brake cylinder is injured so as to be inoperative, it is cut out of the system by turning a tap. The arrangements and the mode of working have been frequently explained in back volumes.)—R. E. C. (If you mean Dagam wood, you will find all we know about it on p. 279, last volume.)—W. P. (We do not know; but the principle is old. It is a question of the neatest and best way of utilising it.)—Engineer. (You can be apprenticed for the sum named to a mechanical engineer; but it would be advisable to seek a shop in which they do general repairs as well as make engines.)—Turk. (If you would only look through back volumes you would find ample information about French polishing. See pp. 175, 227, Vol. XXXII., for instance. You might wait until such a query reached the U.Q. column, for it is tolerably certain that it has not been answered because so much information on the subject has been given before.)—G. M. H. (See indices. Electric bells are scarcely novelties nowadays, and you can get the parts from any of the dealers.)—Poor Man. (The only thing that can be done is to obtain the best medical advice. We do not know of any institution for such cases.)—James R. Hargan. (We do not remember the "controversy," and would advise you to consult an ophthalmologist if there is anything the matter with your eyes.)—Amateur Binder. (See indices, or p. 377, Vol. XXX. For illustrations of the lying press and plough, procure a list from the makers. No. 388 contains a hand press, and No. 613 a plough and stitching frame in an article on Amateur Bookbinding.)—A Sister's Friend. (It is a hard case, but you can do nothing if your sister is a consenting party; or if she is not, you are equally powerless if she is over 16.)—One in a Fix. (It can be stamped at any time on payment of a £10 penalty. The copy retained by the apprentice need not be stamped at all.)—S. Smith. (You will have to send it to the makers; but you will save time and money by throwing it away and getting a proper filter with an animal charcoal or spongy iron filtering block accessible at pleasure, so that it can be scrubbed or scraped clean once a fortnight.)—Albert H. Williams. (You should have repeated the query. If it has not appeared this week, and has not been replied to in this column, it has either not reached us, or is against the rule of "Hints to Correspondents No. 4.")

## USEFUL AND SCIENTIFIC NOTES.

**Verbascum for Consumption.**—From time immemorial verbascum has enjoyed considerable reputation as a remedy for phthisis. The Irish peasants employ by preference the leaves of the large Verbascum thapsus. They use 100 grammes of the fresh leaves or 30 of the dried in a litre of fresh goat's milk: this mixture, allowed to macerate for ten minutes, is then filtered, sweetened, and drunk warm. Two or three litres are consumed every day. Dr. Quinlan has tried this treatment for a period of two years in 127 patients. He believes that in the premonitory and "pre-tubercular" stage of consumption, the remedy possesses curative and nutritive properties more marked than those of cod-liver oil, and nearly equal to those of koumiss. The increase of body weight is certainly due to the verbascum, since the milk alone does not yield the same results. The remedy effectually relieves cough, checks diarrhœa, and alleviates all the symptoms of consumption except the sweatings. The leaves, smoked like tobacco, relieve the symptoms of irritation of the respiratory passages. —*Lancet*.

**Metre v. Yard: Kilo v. Pound.**—Writing in an American journal, Mr. Coleman Sellers says: "If a bar of ordinary forged iron be planed up to measure 1in. square, and the bar be one English yard long, it will weigh 10lb., and the tenth of such a bar will weigh 1lb. more accurately than will the ordinary litre of water weigh 1 kilo. The English engineer, in these days of iron, knows when he uses shapes of iron, rolled of uniform section, that the tenth of their weight in pounds per yard gives him the area of the section, and this one admirable incident will long fix the desirability of the present unit of England and America."

With the object of producing manganese copper in a readier and less expensive way than at present, Mr. G. A. Dick melts pure copper in a crucible with ferro-manganese containing a large percentage of manganese, and in the presence of silicium. When pouring out into ordinary moulds, the manganese will be found to have combined with the copper, and the silicium with the iron, the latter forming a layer upon the manganese copper. The greater the amount of silicium present the more perfect is the separation, though even so small a quantity as 1 per cent. of silicium as compared with the manganese present suffices for the desired effect. In some cases the ferro-manganese contains in itself sufficient quantity of silicium to produce the necessary reaction upon the iron so as to set the manganese free to combine with the copper.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette*.—Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists, London."—Also makers of Epps's Chocolate Essence

## TERMS OF SUBSCRIPTION.

### PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., and XL., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words | 2 | 6 |
| Every additional eight words | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words | 0 | 3 |
| For every succeeding Eight Words | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words | 0 | 6 |
| For every succeeding Eight words | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Holloway's Pills.**—Throughout the seasons good health may be maintained by occasional doses of Holloway's Pills, which purify the blood and act as wholesome stimulants to the skin, stomach, liver, bowels, and kidneys. By a timely recourse to them the first erring function may be reclaimed, suffering spared, and life saved.—[ADVT.]

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—Caplatzi, Science Depot, Chenies-street, near British Museum. Established 1862.

**Lathe Head,** 7in., cones for lathe wheels and lathe heads, gut, turned and bored bicycle fittings. Exchange offers to W. Smith, Bilston-road, Wolverhampton.

Wanted, collection of above 1,000 **Stamps** in exchange for Books, Scarf Pin, Electric Bell, Batteries, and other Electrical Apparatus.—H. Bunting, Didsbury.

"**Electrical Reviews,**" bound: also English Mechanic (unbound), several volumes of each. Offers wanted. Also some Electrical Apparatus.—R. C., 1, Canonbury-lane, Islington, N.

**Dynamo Castings,** 800 c.p., with all fittings, on mahogany bed, nearly ready for using. Exchange for 54 Bicycle, or Photographic, or offers. Also Lamp and Bunsen Batteries.—C. H. Hatch, Alderley Edge, Nr. Manchester.

Four Vols., from 1 to 48 parts of "**Science for All,**" illustrated, clean, unbound. Exchange Model Engine, or offers. —R. Walker, James-street, West Stanley, R. S. O. Durham.

What offers for Tait's Double-action **Air Pump,** 7in. plate (equal to new), four receivers, Induction Coil, 1in. spark, 1 dozen vacuum tubes, 4-cell and 2-cell Bichromate Batteries, 20-candle Dynamo, with wire, unfinished, and sundries. Want good whole-plate Photo. Lenses and Burnisher.—G. M., 12, Victoria-road, Twickenham.

Victoria 2-Lens **Camera,** nearly new; 100 Sheets Albuminised Paper, quantity of Gem and Victoria Mounts, &c., &c., for good Microscope, or anything useful.—W. Sharpe, Madeley, Salop.

What offers, 30 2s. parts of "**Modern Mechanical** Engineering and Machine Making," by R. Scott Burns.—W. N. Cooper, 21, Upper Park, London, N.

**Lathe,** 3in. centre, complete, value £4. Exchange for 53 or 54in. Bicycle; must be in good condition.—A. E. Bowers, 5, Gloucester-road, Kew, S.W.

Exchange good Cocoa Concert **Flute,** 8 German-silver keys, mounted on pillars, for ½-plate Bellows, Camera, and Backs for dry-plate work.—R. D. Abney, Malahide, Co. Dublin.

56in. **Bicycle,** dropped handles, gunmetal hubs, suspension saddle, lamps, &c., thorough order. Exchange.—C. Braddock, jun., Long Ditton, Surrey.

**Tricycle Lamp,** in good condition, cost 15s. Offers exchange.—P. G., 112, Belvedere-road, Lambeth, S.E.

New hand-power radial **Bench Drilling Machine,** takes 3ft. diameter, self-acting variable feed, quick return, instantly charged. Offers invited.—Henry Kilburn, Bishop Auckland.

"**English Mechanic,**" 216 numbers, Volumes XXIII. to XXXVIII. (some volumes complete). Exchange for any of volumes XIII. to XVIII., or offers.—James Monroe, Ramsgate.

7in. by 5in. Rigid Bodied **Camera,** with good rackwork Portrait Lens. Will exchange for Orguinette; must be perfect.—G. Waller, 2, Middlegate-street, Gt. Yarmouth.

Wanted a small **Gramme Dynamo,** with fine wire armature. Good exchange.—A. Percy Smith, Horton-street, Rugby.

**Gas Machine,** the "Sun," cost £25. Will exchange for good Tricyle or Safety Bicycle.—M. E. Horley, Horticultural Works, Toddington, Beds.

Half-plate new **Burnisher.** Exchange for good half-plate Camera, no lens.—H. Smalley, Photographer, Kings hill, Wednesbury.

Will exchange first-class **Micro Objects,** for Vacuum Tubes, &c.—W. White, 17, York-street, Nottingham.

**Electro-Motor,** Chaster's form, armature 3in. by 1⅝in., very powerful, suit small lathe or fret saw.—J. S., 4, Oak-street, Radcliffe, near Manchester.

"**Knight's Mechanical Dictionary,**" complete, supplement to date, 102 7d. parts. Offers in exchange.—G. Mackie, 2, Collingwood-street, Newcastle-on-Tyne.

Treadle **Lathe** wanted. Exchange several first-class Fishing Rods, ebonite reel, silk, hair lines; if preferred, 30s. Microscope.—Address, K., 5, Frederick-street, Leicester.

Three years' "**Journal Society Chemical Industry,**" to exchange for Books on Metallurgy or Electricity.—J. Innes, Llanelly.

Wanted, small hand-power **Dynamo,** Gramme preferred; state wants.—J. Innes, Llanelly, Carmarthenshire.

**Boiler,** multitubular, full half-horse, wanted, copper, iron, or steel, sound, perfect, and cheap; exchange Spade Guinea; if engine attached would buy.—54, St. James's-road, Stratford, E.

5in. centre **Slide-Rest,** by Cunliff and Croom, good as new; will exchange for 52in. Bicycle, Humber, Rudge, or Invincible.—Apply, F. Underwood, Beverley.

Fifty yards new **Chain,** weighs nearly two cwt., cost 45s., for 40ft. 6in. Belting, same value, or offers.—Vokes, Chalk-lane, Hull.

Tough, mild, weldable **Steel,** ¼ to 1in. dia., or square. Offers requested for ½ to 10 cwt.—Gilbert, Oxford-road, Sheffield.

**Mild Steel,** specially rolled for dynamos, shafts, &c., from 1in. dia. sawn to any lengths. Will exchange for anything useful.—H. Gilbert, Oxford-road, Sheffield.

**Calculating Circle,** Baucher's patent, watch size, new; will exchange for Micrometer Callipers, or anything useful. —Mackintosh, jun., Ibsley, Pennsylvania, Exeter.

Best Cast **Steel,** 7-16 to 1in. dia., short bars; offers requested; sample sent on application.—Gilbert, Oxford-road, Sheffield.

First-class 4ft. **Lathe Bed,** standards, flywheels, treadle, by Milnes, Bradford, to exchange for 52in. Bicycle, Humber, or any best make.—F. Underwood, Beverley.

Pulvermacher's **Galvanic Chain Band,** cost 50s.; would exchange for Electrical Goods, Bell, &c., or offers.—W. F. C., 5, Brand-street, Greenwich, S.E.

**Induction Coil.** What offers? No use for it.—Roberts, 31, High-street, Mold.

"**English Mechanic,**" Vols. I., II., and III., nicely bound, 128 Nos. unbound, from 1880 up to present date; 8 copies of "Modern Thought," a Side Drum, set of 6 beautiful Plaque Casts from the "Flamingo Boys," in S. K. Museum, and Humble and Nicholson's Patent Washing Apparatus. What offers in the Bicycle or Tricycle way?—Letter first to J. H., 51, Heygate-street, S.E.

Wanted, **Engine and Boiler,** complete, not less than half h.-p. Exchange 5in. centre lathe, with slide-rest and tools.—Pritchard, 119, Raglan-road, Plumstead.

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Motor Castings,** materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—King, Mendham, and Co., Bristol.

**Insulated Wire Table,** showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—King, Mendham, and Co., Bristol.

**Standard Ohm,** in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—King, Mendham, and Co., Bristol.

**Wimshurst Influence Machine.**—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—King, Mendham, and Co., Bristol.

**Galvanometer Cards,** improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free.—As above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Trouser Lengths,** 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—Hewitt, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot,** 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—Millar, Proprietor.

Hard **Vulcanised Fibre** for Magnet Heads.—Mossés and Mitchell, 68a, Chiswell-street, London, E.C.

Hard **Vulcanised Fibre** for all kinds of insulation. —Mossés and Mitchell, 68a, Chiswell-street, London, E.C.

**International Inventions Exhibition,** East Avenue, Group 21, Stand 1683.—Mossés and Mitchell, 68a, Chiswell-street, London, E.C.

Tudsbury and Sons' "High Tension" **Wimshurst** Machines, with Compound Ebonite Plates. List, one stamp.— Edwinstowe, Newark.

24 **Microscopic Slides,** in box, very cheap. List sent for stamp.—Well, Dalmain-road, Forest Hill.

**Lathes,** Lathes. Cheapest and best. List, 2 stamps. Nothing equal at price.—Robinson, Somerset-road, Sheffield.

100 **Foreign Stamps**, including Brunswick, Ceylon Tasmania, Egypt, Greece, Luxemburg, free 7d.—Hely, Foley-street, London.

**The Kinetic Engineering Company**,-36 and 37, Brooke-street, Holborn, London. Circulars and list post free.

**Dynamo Wire**, 1s. 2d. per lb. Line Wire, 23s. 6d. per mile. Pushes, 4s. per dozen.—Kinetic Company.

**Leclanche Cells**, best. No. 1, 16s.; No. 2, 19s.; No. 3, 22s. 6d. per dozen.—Kinetic Company.

**Electric Bells**.—Best quality, workmanship, appearance and value in market, 40s. per dozen.—Kinetic Engineering Company.

**Electric Lighting**. — Catalogues of Dynamos, Lamps, Fittings, &c., post free.—Kinetic Engineering Co.

**Electrical Supplies**. Wholesale only.—Kinetic Engineering Company, 36 and 37, Brooke-street, Holborn, London, E.C.

Gravet's **Slide Rule**, recommended by H.M. Government officials. Write for prices and testimonials.—Sole Agent, Farrar, Benson's-buildings, Leeds.

**Chemical Apparatus**. — Catalogue, 90pp., 500 illustrations, posted 2d.—W. Hume, Lothian-street, Edinburgh.

**Photographic Apparatus and Chemicals** for professionals and amateurs. See new illustrated catalogue, post free.—Hume, Lothian-street, Edinburgh.

Brazilian Pebble **Spectacle Glasses**, rough slabs or polished.—Richard Baker and Co., 9, Mincing-lane, London.

Brazilian **Pebbles and Crystals**.—Richard Baker and Co., 9, Mincing-lane, London.

**Mica**, otherwise Talc.—RICHARD BAKER & CO., 9, Mincing-lane, London.

**Planing**, not exceeding 10in. by 10in. by 8in.—B. W Cleeo, 18, Belinda-street, Hunslet, Leeds.

For **Model Work** (wheel-cutting in brass only); also Boring, Turning, and Screw-Cutting.—Cleeo, as above.

**French Polishing**, Staining, Painting, and Varnishing. 122 Recipes or Trade Secrets, with full instructions and details, post free, 1s.—I. Tomlin, 28, Highfield-terrace, Barnsley, Yorkshire.

**Castings**.—Half horse-power Horizontal, Vertical, or Launch Engine Castings, complete, with brass work and forgings, 12s. 6d. One horse-power, 25s.—Tomlin, Highfield-terrace, Barnsley, Yorkshire.

**Castings**.—Bench Drilling Machine Castings, complete, 3s. 6d.—I. Tomlin, Highfield-terrace, Barnsley, Yorkshire.

**Castings**.—All Brass Engine Castings, horizontal or vertical, suitable for model work, 2s. 6d. set.

**New Designs and Price List** of Perfected Engines and Castings. post free.—I. Tomlin, Engineer, 28, Highfield-terrace, Barnsley, Yorkshire.

**Bottles for Chemists**, Wine and Beer Merchants, sample tubes, cases, and boxes.—Edward W. Drury, Hull.

**Optical Glass** of finest quality, crown and flint; all sizes in stock to 14 inches diameter, discs and sheet.—Buckingham, Blenheim-grove, Peckham.

Cotton-covered **Wire**, D.C. 10 to 18, 1s. 9d.; 20, 22, 24, 26, at 2s., 2s. 3d., 2s. 6d., and 3s. per lb.—C. Darvill, 8, Brent View-road, The Hyde, London, N.W.

Celebrated Kerry **Ferns**, 12 varieties, including bridge filmy, 1s. 6d. free.—FitzPery, Rathanny, Tralee, Kerry.

Pumphrey's **Pocket Tripod**, for cyclists, professional and amateur photographers. Perfectly rigid. May be had on approval. Illustrations and testimonials free.—Pumphrey, Stanhope-street, Birmingham.

Pumphrey's **Hydrostatic Shutter** for instantaneous and timed exposures. Photographs done with it. Free, price 10s.

Pumphrey's **Camera and Lantern**, with 54 illustrations. 2 instantaneous photographs. Full instructions, 2d. post.

Eighty sets **Lantern Photographs** at reduced price. Illustrations of 20 sets post free.—Pumphrey, Stanhope-street, Birmingham.

**Engine**, horizontal double oscillating cylinders, ½-horse, price £6, little used.—Journey, 194, Great Portland-street.

**Insulated Wire**, best quality only. Price list free. —Maw, removed to 63, St. James's, Brixton, London, S.W.

**Brass Cylinders**, accurately turned and beautifully finished, with slide-valve, 16 screws, &c., fitted complete materials and workmanship guaranteed very best, and can be had on approval by deposit. 1in. stroke, 5s. 9d.; 1½, 7s. 9d.; 2in.. 10s. 6d.—H. F. Lovegrove, Optical Works, High-street, Slough.

**Strange Fact**.—Although the cylinders (as above) have been sent on approval to various parts of the kingdom, yet up to this date (May 20th, 1885) not one has been returned.

**Showcases for Exhibitions**, Models, Scientific Instruments, Nests of Drawers, &c., &c.—Fry and Co., Shop-fitters, 90, Borough-road, London.

**Homœopathy**.—Laurie's "Epitome of Homœopathy," 540 pages, together with solid morocco case, containing 44 medicines, complete, price £1.—T. C. F., 332, Strand, W.C.

**Printing Presses**, from 10s. to 50s., complete numerous testimonials.—Manufacturers, Adams Bros., Daventry.

**Refractors and Reflectors** for sale, a 4¼in. Cooke (old Thomas), Equatorial.—G. Calver, Widford, Chelmsford.

Model **Steam Engines** made or repaired. Separate parts fitted up, boilers made to order.—Lucas and Davies, 21, Charles-street, Hatton-garden, London.

3in. centre **Lathe Heads**, several for sale, cheap new.—C. Pool, Tool Maker, 30, Hockley, Nottingham.

3½in. back-geared **Heads**, hardened double coned, steel mandrels, phosphor bronze bushes.—Pool, as above.

New Illustrated Price List of **Screws, Bolts, and** Nuts for Model Work, drawn to actual size, sent on receipt of stamp.—Morris Cohen, 132, Kirkgate, Leeds.

**Binocular Microscopes and Apparatus**. stage and stand condensers, polariscopes, and all accessories. Alterations and Repairs for the trade.—R. G. Mason (from J. Swift), 24, Park-road, Clapham, London, S.W.

**Launch Engine**, 3in. bore, feed pump, complete, vertical boiler, 1ft. 9in. diameter, 3ft. high, 19 tubes, lagged and fittings, complete, £25.—S. Smith.

**Propellers**, improved pattern, from 12in. to 30in., in stock.—S. Smith, 11, West-street, Soho, W.C.

For sale (by Singer), a three-in-hand **Tricycle**, good, clever, cost £40; price £10; also American Star Bicycle, cost £22, six guineas. Rear-steer Tricycle, £7.—Dyer, 124, Falcon-road, Clapham Junction.

Scottish Scenery **Photographs**, 7in. by 4in. size, extraordinary value, 4d. each.—Address, Photo, 182, Trongate, Glasgow.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight.—Clarkson, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—Clarkson, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles: prices on application.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. Clarkson, 28, Bartlett's-buildings.

**Eyepieces**.—Huyghenian of any power to fit any telescope, 15s. each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes**, second-hand, by best makers.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

**Oils**, lubricating, or Lardine: expired patents. Send for instructions.—J. M., 6, Hamlet-street, Bootle, Liverpool.

**New Time**.—Alter your Clocks and Watches. Twelve Sets of figures, with instructions, 6d.—Wheeler, Preston.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings**.—Improved Registered Designs; sets 4in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors**.—Complete one horse-power. £9. Half, £6; Quarter, £4; Eighth, £3.—Thomas Wheeler, Preston

**Gas Engine**, 3-man, Barker's Patent Universal, good as new, £28. All my extra fittings.

Also Patent **Band-Saw Machine**, on stand, two saws, hand or power.—10, Darby-road, Folkestone.

Steel **Name Stamps**, 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d. per post.—B. F. Baldwin, Robinswood-hill, Gloucester.

Model **Engine Castings**, brass and iron, superior quality. Lowest prices. Also full-sized Working Drawings.—Hughes.

Horizontal, Vertical, Launch, and small-power **Engines** of every description. Catalogue and six designs, 6d.—Hughes.

Brass **Castings** for following articles:—Iron Stands, 1s. 6d. each. Tobacco Cutter, 4s. Roasting Crane, 5s. 6d.—Hughes.

Pair **Brackets** for mantel rods, 3s.; Knobs for rods, 1in., 2s. 6d. pair; ⅞in., 2s. 3d. pair, post free.—Hughes

Amateurs supplied with **Castings** from own patterns. —Hughes' Mersey Dockyard, 17, Smith-street, Kirkdale, Liverpool.

**Arc Lamps**, very simple, work with small dynamo, 100 c.p., carriage free, 6s.—Habgood.

**Wheatstone's Bridges**, accurate, 3s. 6d., carriage free.—W. Habgood, Hazlebrook, Buccleuch-road, West Dulwich, London, S.E.

**Recipes**.—STANLEY, 119, Manchester-road, Poplar. (Terms, this column, May 22.) Add "Horehound Beer," "Babbit Metal," Coaguline.

**A New Varnish** (a Spirit Copal), clear as water or plate glass; never before produced; dries in five minutes; hard, durable, and brilliant; a bottle, post free, 13½ stamps.—Mr. Stent, 5, Coventry-street, London, W. Established 30 years.

For sale, a first-class new 6in. compound **Screw**-Cutting Lathe, with dog and other chucks and lathe tools; also a full set of Screw-cutting Wheels, all parts bright, made by an engineer, a great bargain, £20, worth three times the amount. —E. Brennan, Coley's Buildings, Whessoe-lane, Darlington.

**Dynamos**, all sizes, new and second-hand, Motors, fine Hand Dynamo, lamps, wire, and every requisite for any sized installation. Write for prices, testimonials.—Warne, 39, St. John's-street-road, E.C.

Nearly new 2¼in. Dudgeon's **Tube Expander**, two sets of rollers, 30 shillings.—Hurst, Fire Station, Bolton.

Low Moor Iron Vertical **Boiler**, 5ft. 3in. by 2ft. 6in., with 7in. cross tube; guaranteed to work at 100lb. per square; with all mountings, complete, price £17.—W. Hurst, Sidney-street, Bolton.

Fine Achromatic **Telescope**, perfect condition, table stand, cabinet, twenty-five shillings.—Dickenson, 8, Woodsley-grove, Leeds.

Slow-combustion ornamental **Stove**, nearly new. (Tortoise). Price 30s., or offers.—L. G., 5, Factory-terrace, Halstead, Essex.

**Steam Launches and Engines**, Boilers and Propellers for same. All sizes. State requirements.—Greenhall, Eastville, Bristol.

Mahogany **Telescope Tripod**, brass mounted, legs take in three parts. 15s., offers.—H. Rule, Hampton, Middlesex.

**Piles**.—Worst cases cured first application. Indian Ointment, sent 13 stamps.—Thomas Palmer, St. Helen's, Auckland, Durham.

**Wires**.—Silk-covered, No. 26, 4s. 6d.; 24, 4s. 5d. per lb., post free.—Scott, Basuto-road, Fulham, S.W.

**Pushes** (sprung), 3s. 9d. doz., post free. Pears, 7s. 6d. doz., free. Indicator Movements, 3s. 3d. each, free.—Scott.

Leclanché **Batteries**, No. 2, post free, 2s. 6d.—R. Scott, Electrician, Contractor to Her Majesty's Government.

**Lathe**.—Good 4in. Screw-cutting Lathe, with gap bed, new, £14.—Middleton, 16, Hope-street, Glasgow.

**Launch Engines**, from 3in. cylinders up to 9in. cylinders, for sale.—Middleton, 16, Hope-street, Glasgow.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. Jones.

**Dynamo Castings**, Jones's patent H: 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s.; 70, 16s. a set.—H. Jones.

**Dynamos**, finished: 8 c.-p., 30s.; 16, 36s.; 20, 40s.; 30, 50s.; 70, 100s. each.—H. Jones.

**Dynamos** for house lighting.—Jones's Patent Laminated Fields and Armatures, 5, 6, and 7 lights, £6, £7, and £8 each.—H. Jones.

**Dynamo Machines Repaired**. Motors, with wire, 6s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

3in. centre **Lathe**, slide-rest, few chucks, complete, £3 10s.—Rudd, 281, Dumbarton-road, Glasgow.

Sets of **Castings** for Milling Frames, with vertical adjustment. All parts planed. Price £1.—Below.

Wrought-iron **Rings for Dynamos**, all sizes. Stamped envelope for particulars.—Wm. Allsop, Derby-road, Belper.

**Am-meters**, 40 amperès, 6s. 6d.; 20 amperès, 5s. 6d.; Voltmeter, 10s. 6d.—W. A. Walton, London-road, Gloucester.

"**Marche Fantastique**," new march for piano, &c., post free, 6½d.—Johnson, Organist of St. Charles, Measham, Atherstone.

**Standard Ohms**, 2s. 6d. each. Delicate Galvanometers, astatic, 5s.—S. Bottone has a few for Sale.

**Am-meters**, indicating up to 8 amperès, 5s. Voltmeters, 5s. Model Electro-Motors, 5s.—S. Bottone.

**Wheatstone's Bridges**, accurate up to 1,000 ohms, 5s. each, post free.—S. Bottone, Stanley-road, Carshalton.

Children's **Tricycles**, 8s. Youths', 43s. Adults', 103s. Youths' Bicycles, 50s. Adults', 83s.—33, Porthope-road, Birmingham.

A splendid Landscape **Lense**, 3¼in. diameter, and portable mahogany Camera; a rare chance for professionals or amateurs; bargain, £4.—Richard Long, Youghal, Co. Cork.

**Inventors and Amateurs Assisted** in making Instruments, Models, Patterns, &c.—B. Orick, 24, Woodbridge-street, E.C.

**Character Read** by Lines of the Hand. Chart, explanations, 7d.—H. Dyer, 21, North-street, Taunton.

Hand **Drilling Machines**. ¾ holes; save much time on outdoor work; from 25s.—S. Beeching, Mareham-le-Fen, Boston.

**Boiler**, 15in. by 19in., tested to 100lb., 3 tubes; also Engine.—S. Beeching, Mareham-le-Fen, Boston.

**Devonshire Cream** (delicious) by improved centrifugal process. ½lb., free, 1s. 6d.—G. Bull, Manor Farm, Martock, Somerset.

**Fresh Butter** of superior quality from the cream, as above. 2½lb., free, 3s. 6d.

An **Altazimuth** for sale.—For description and price apply, W., Bradninch Vicarage, Cullompton.

**Vermilion**, best, 2s. 4d. lb.—PINNELL BROTHERS, 214, Whitechapel-road, London, E.

**Parts Fitted up** at cheap rates. Castings, with all parts turned, from 8s.—J. Spencer, Modeller, 1, Whittaker-street, Burnley.

For sale, cheap, a quantity of **Organ Materials**, new and second-hand.—R. F., 184, Kennington-road, London.

**Sausage Machine**, 24in. block, £6. Combined Engine and Boiler, £17, or exchange.—79, Dudley-road, West Bromwich.

Model **Engine Castings**.—Best and cheapest. See list (stamp) and compare.—Wood, Dalley-street, Broughton, Manchester.

**Microscope** (Bateman's 3-guinea), perfect condition, 25s.; quarter-plate Bellows Camera (Ross), stand, &c., complete, 28s.

Three-inch **Astronomical Achromatic** (Bateman's), eyepieces, stand, &c., complete, 38s.—Stamp, Burton, 187, High Holborn, London.

50 **Sewing Machines**, Howe, for leather, cost £8, offered £2 5s. Singer Medium, for cloth, cost £6 10s., offered £2 15s. First-class order. What offers in exchange?—Clayton, Plough-corner, Colchester.

Coventry Rotary Pattern **Tricycle**, offered £10 10s. cash, or good exchange £16; only used a few times.—Clayton.

**Sewing Machines**, about a dozen No. 2 Thomas, cost £10 10s. each, offered £2 10s.; suit a factory or dealer. What in exchange?—Clayton.

**Indiarubber Wringers**, cost 30s. Made to screw to washtub, offered 15s. 6d. each. What offers for one or twenty? —Clayton, Plough-corner, Colchester.

**Microscope**, by Dolland, cost 8 or £9, offered for £4, or exchange to £8.—Clayton, Colchester.

Marvels.—Double **Opera and Field Glasses** from 5s. 6d. Lists, with engravings, one stamp.—J. B. Dancer's Opera Glass Depot, 63, Hamstead-road, Handsworth, Birmingham.

Large **Medical Coil** for sale, wound especially for medical uses, with 5 powers; will give shocks from very slight to ones of very great intensity. To be sold cheap.—Mr. J. Gray, 16, Pancras-road, N.

Superior Concert **Flute**, Cocoa, cylinder bore, eight German silver keys, in mahogany case, £5, or offers. Approval if required.—E. Hills, Brompton Barracks, Chatham.

Inch Spark **Coil**, condenser, commutator, discharging pillars, 38s.; bargain.—J., South Cottage, Thurlow Park, Dulwich.

"**Hints on Egg Collecting**." Illustrated Pamphlet, 2d. Drills and Blowpipe, 1s. free.—W. Davis, Naturalist, Dartford.

**Circular Saw Bench**, iron treadle, take 7in. saw, angle guide, good condition, £6.—98, King's-road, Camden-road, N.W.

Simple and Inexpensive **Recipe** for Making Ginger Beer, 9d.—T. James, junior, Stratton-on-Fosse, near Bath.

**Gas Engines**, 1 to 4 man-power, simple, strong, cheap. Numerous references.—Ellis Butterworth, Rochdale.

Small Vertical **Boiler**, 14in. by 3ft. 6in., firebox and all fittings, £3 10s.—Abraham Auty, Emley, near Wakefield.

Quantity of **Dye Wood**, reduced to powder, fine quality; sample sent; offers wanted.—Thos. B. Hown, Newbury, Berks.

**Stammering Cured by Correspondence**.—"Practical Guide," and 600 Cases, 1s. 4d. Book of testimony (1s., or returned).—N. H. Mason (B 40), 18, Stavordale-road, Highbury, London.

Improved **Rubber Stamps**. Your name, business and address, 1s. 2d.—F. Harrison, 8a, Southwell-street, Liverpool.

**Le Merveilleux**, ¼-plate, with brass scales and weights, &c., 17s.—H. Millar, 66, Constable-street, Dundee.

**Brassfinishing**, Bronzing, Lacquering, and Burnishing done cheap.—Write Porteous, 32, Brewer-street, London, W.

For sale, cheap, **Circular Saw Bench**, hand or steam, by Reynolds, London.—White, Bellevue-road, Southampton.

**Melicerta Ringens**, the tube-building rotifer, a rich tube, post free, 8 stamps.—Blackshaw, 4, Ranelagh-road, Wolverhampton.

Capital Gentleman's **Gold Lever Watch**, splendid timist, perfect order, 60s.—C. Thompson, 153, Lodge-lane, Liverpool.

"**Paints**."—A few numbers of this valuable work, for making all kinds of paints for sale at Gotelee and Son, Booksellers, Hounslow. Price 1s.

**Dynamo Wire**, No. 18, best double-covered, 1s. 8d. per pound.—D. Walton, King-street, Hebden Bridge, Yorks.

**Surveying Instruments**. — Theodolite, Level, Sextant, Compass, &c., half cost price, nearly new.—S., 20, Montpelier road, N.W.

**Plating Dynamo Machine**, to work by hand or power, cost £18 18s. Price 5 guineas.—S., 20, Montpelier road, N.W.

A two-man Bischop **Gas Engine,** latest patent, same as exhibited at I. Exhibition, quite new, £32. Seen at A. KOERNER, 44, Frith-street, W., London.

**Fishing Bait.**—Red Ching.—This celebrated Chinese bait received first prize in Fisheries Exhibition. Will keep for years. Salt and fresh water fish, attracted from a long distance in large numbers by its peculiar odour and colour, take the bait voraciously. One packet will take bushels of fish. Post paid, 1s. 2d.—Agent DR. EVANS, Importer, Shirley, Southampton.

**Liverpool Astronomical Society**—Just out; Vol. III. of the "Journal," 140pp., illustrated by 40 lithographs and wood-cuts, and containing 100 papers on astronomical subjects, index, &c. Stiff paper 4s., post free. May be had of the SECRETARY, 42, Irvine-street, Liverpool.

Tourist **Telescopes.**—See Catalogue, with testimonials.—FRANCOIS.

**Spectacles and Eyeglasses,** guaranteed to meet approval. Over 2,000 pairs London Smoke sold.—FRANCOIS.

**Field Glasses.**—First-class articles at very moderate prices. See Catalogue, 2 stamps.

Model **Steam Engines** from 2s. to £5. Steamboats from 4s. 6d. See Catalogue, second edition.—FRANCOIS.

**Repousse Work.**—Every requisite, with instructions, supplied by A. FRANCOIS, Ryland-road, Birmingham. Particulars on application.

**Coca Leaves.**—You require nothing but these at Whitsuntide. No necessity to carry heavy luncheon bags.—MARKS and Co., 17, Newcastle-street, Farringdon-street, E.C.

**Coca Leaves.**—The Bolivian Consul-General has sent a splendid testimonial this week in favour of their stimulating properties.

**Coca or Cuca Leaves.**—Many M.P.'s and Clergymen take them constantly. To Cyclists they are a positive necessity.

Persons afflicted with **Indigestion** should chew Coca instead of eating a hearty dinner, and they would soon be cured.

**Coca Leaves.**—Sample Packet, with medical and scientific opinions, 13 stamps.—MARKS and Co., 17, Newcastle-street, Farringdon-street, E.C.

**Coca Leaves.**—Fresh consignments of grand quality just received.—MARKS and Co., 17, Newcastle-street, Farringdon-street, E.C., London.

**Incandescent Carbon Lamps,** low resistance, 3s. each. Fairy Lamps, 3s. 6d. Platinum Lamps, 1s. 3d., post free.—TODD, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders,** new pattern, best in the Trade, 12s. dozen. Sample, post free, 1s. 3d.—TODD, as above.

"**English Mechanic,**" Vols. XXV. to XXXVI., perfect, 15s.—JOHN LAPTHORN, 122, New Church-street, Jamaica-road, Bermondsey.

**Music,** piano and violin trios, &c.; early ENGLISH MECHANICS, in parts.—E., 130, Disraeli-road, Putney.

**Universal Trade** and Amateur Supply.—Lecture requisites; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—CAPLATZI.

**Model Engines,** Boats, Boilers, Gauges, Cylinders, Screws, and Bolts; Fittings, new, second-hand; cheapness unequalled; ½ to 2 h.p.

**Fairs, Public Shows.**—Electric and Weighing Machines, Camera Obscuras, Polyramas, Lung Testers, large Telescopes, Mechanical Models; great attractions.

**Photography.**—Large quantities of Wet and Dry Plate Apparatus, Lenses, Instantographs, Copying Cameras, Tents, Stands, Focussing Glasses, Printing Materials; cheapest in London.

**Astronomy.**—Special attention to our best warranted O.G.'s, E.P.'s, Finders, Diagonals, Stands, and complete instruments is invited.

**Microscopes.**—39 Monocular, Binocular, and Antiques. Fine Powers, Condensers, Polariscopes, Camera Lucida, Lamps, Accessories of all kinds. Unequalled cheapness.

**Telegraphy.**—Morse Printers, Sounders, A B C's, Needles, Bells, Indicators, Phonographs, Galvanometers, Resistance Coils, Testing Instruments, Materials, Fittings; all kinds.

**Type Writers,** Printing, Litho, Copper-plate Presses. Jeweller's Flatting Mills, Stamping Presses, Dyes, Vulcanisers, Photo Burnishers, &c.

Catalogue, 2d. **Caplatzi,** Science Depot, Hire and Exchange, Chenies-street, Tottenham-court-road. See 15 years' advertisements.

## Wanted.

Old Microscopes, by Adams, Amici, Baker, Dollond B. Martin, Pritchard (Goring's "Engiscope"), Varley, and other old makers.—J. MAYALL, Junior, 224, Regent-street, London, W.

Agents Wanted on commission to sell a new Invention to users of steam power.—Apply SALFORD INJECTOR and EJECTOR Co., Salford.

Agents Wanted.—Morgan's celebrated Improved Scale Preventing Compound. Nothing better or cheaper.—W. H. MORGAN, Engineer, Gloucester.

Birmingham Goods, Jewellery, Watches, Furniture, &c. Agents wanted. Illustrated Book and Perambulator Price List, post free.—HENRY MAY, Birmingham.

Wanted, Vol. III., IV., V., of "Holtzapffel's Turning, &c."—JOHN FLETCHER, 37 and 38, Seething-lane, London, E.C.

Wanted, Thompson's work, Dynamo Electric Machinery, cash.—C. O., 144, St. Paul's-road, Canonbury, N.

Wanted, Rotary Tricycle, hand-power, front steerage preferred.—Address, JOHN COLBY, Plashendre, Aberystwith.

Can any reader recommend plain, comfortable Farm House Apartments, on the South or East Coast, within easy reach of London, during August?—Address, K., Lady Cross, Harrow-on-the-hill.

Wanted, Contributions for Periodical from experienced workers at Botany, Geology, Astronomy, Chemistry, and Zoology.—Letter to J. A. C., Presford House, Derrington, near Stafford.

Useful Novelties wanted for large trade connection. Makers may open good business by communicating with Mr. HAYDON, 128, Strand, who pays for all selected samples.

## Addresses.

To "Invicta," for Steam Motor.—Please address, C. BERRY, Hollins-terrace, Sowerby Bridge.

## Educational.

French rapidly taught by Mons. ROUSSEAU, of Clarendon-road, Walthamstow. Twenty years professor in England. He places at the disposal of his pupils a laboratory well fitted for electro-deposition of metals.

## Situations.

A Blacksmith (shoeing or general) wishes a constant Situation; is steady, obliging, and efficient in the business.—Address, E. CLARKE, care W. Bird, Pipe-lane, Peterborough.

Situation wanted, by a practical hand; used to the making and fixing of electric bells, burglar and fire alarms, indicators and fittings, brass finishing, telephone, speaking tubes. Address L. FORD, Witham, Essex.

Machinist Wanted.—A practical mechanic to superintend the giving out and good workmanship of small machines in brass, steel, and iron.—Apply to M. 514, Messrs. Deacon, Leadenhall-street.

Scientific Instrument Maker seeks situation as assistant to scientific gentleman, in laboratory, or in any place of trust. At present engaged in optical trade.—Address, 99, Northcote-road, Wandsworth Common, S W.

CITY AND GUILDS OF LONDON INSTITUTE.—CENTRAL INSTITUTION.

Summer Courses of Lectures and Laboratory Instruction for TECHNICAL TEACHERS and others to be held in the Institute's New Buildings in EXHIBITION ROAD.

I. On the Teaching of GEOMETRY in its TECHNICAL APPLICATIONS—

By Professor O. HENRICI, LL.D., F.R.S., commencing on Monday, June 22nd.

II. On the TESTING OF MATERIALS OF CONSTRUCTION, with some Applications to the DESIGN OF MACHINERY—

By Professor W. C. UNWIN, M.I.C.E., commencing on Monday, July 6th.

III. On the teaching of ELECTRICAL ENGINEERING—

By Professor W. E. AYRTON, F.R.S., commencing on Monday, July 20th.

Courses II. and III. consisting of Lectures and Laboratory Instruction will be illustrated by one or more DEMONSTRATIONS in the International INVENTIONS Exhibition.

Each of the above courses will extend over two weeks, from 10 till 5 daily, Saturdays excepted.

IV. CARRIAGE BUILDING—

Three Lectures by G. A. THRUPP, Esq., on June 29th and 30th, and July 2nd, at 7 p.m.

V. PLUMBING—

Four Lectures, with Demonstrations, by W. R. MAGUIRE, Esq., on July 6th, 7th, 9th, and 10th, at 7 p m.

Registered TEACHERS of the Institute may, on application to the Director, be admitted to any of these Courses without payment of fees.

For further details, and for Syllabuses of the several Courses, apply at Gresham College, E.C., or at Exhibition road, S.W.

PHILIP MAGNUS, Director and Secretary.

---

THE LONDON AND GENERAL PERMANENT BUILDING SOCIETY.

Offices—337, Strand, W.C.

Chairman—THOMAS HUGHES, Esq., Q.C.

VICE PRESIDENTS.

The Right Hon. the Earl of Lichfield.
The Hon. H. F. Cowper, M.P.
Frederick Harrison, Esq.
Vernon Lushington, Esq.
W. Evan Franks, Esq.

Money ready to be advanced on short notice, and in sums of any amount, for the purchase of property or paying off incumbrances. Payable by easy instalments. Expenses fixed and moderate. No Premiums. Managing Director, W. R. SELWAY.

---

ESTABLISHED 1851.

BIRKBECK BANK.—Southampton-buildings, Chancery-lane.

THREE per CENT. INTEREST allowed on DEPOSITS, repayable on demand.

TWO per CENT. INTEREST on CURRENT ACCOUNTS calculated on the minimum monthly balances, when not drawn below £50.

The Bank undertakes for its customers, free of charge, the custody of Deeds, Writings, and other Securities and Valuables, the collection of Bills of Exchange, Dividends, and Coupons; and the purchase and Sale of Stocks, Shares, and Annuities.

Letters of Credit and Circular Notes issued.

THE BIRKBECK ALMANACK, with full particulars, post free on application.

FRANCIS RAVENSCROFT, Manager.

---

**The Birkbeck Building Society's Annual Receipts exceed Five Millions.**

HOW TO PURCHASE A HOUSE FOR TWO GUINEAS PER MONTH, with immediate Possession, and no Rent to pay. Apply at the Office of the BIRKBECK BUILDING SOCIETY, 29, Southampton-buildings, Chancery-lane.

HOW TO PURCHASE A PLOT OF LAND FOR FIVE SHILLINGS PER MONTH, with immediate Possession, either for Building or Gardening purposes. Apply at the Office of the BIRKBECK FREEHOLD LAND SOCIETY, as above.

THE BIRKBECK ALMANACK, with full particulars, on application.

FRANCIS RAVENSCROFT, Manager.

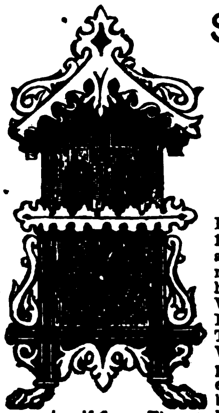
SWISS BAROMETER,



STORM GLASS, AND CLOCK, COMBINED, FOR 5/-

Handsome carved-wood Clock, 14in. high, with ivory hands and figures, works beautifully made in brass, goes for thirty hours with once winding. Will last for twenty years. Keeps most accurate time. The upper part consists of Weather-House; a Swiss male peasant, beautifully modelled, emerges if weather is about to be wet, and a female peasant, same size, if fine. The whole forms an ornament fit for a palace. Both weather-house and clock warranted correct. Sent free in box to any address in the United Kingdom on receipt of postal order for 5s., or two for 9s. 6d. Also fitted with a loud Alarum, which can be set to go off at any time, and loud enough to wake the soundest sleeper, for 1s. extra. Barometer, Clock, and Alarum for 6s.

A SWISS MICROSCOPE FOR 1s.

Long Nickel Silver Case. Magnifies 2,000 times. See the swimming monsters that are living and doing battle in a drop of water! Cheese dust looks like blackbeetles!! Sent free to any address for 12 stamps; two for 1s. 9d.

Note the address.—H. M. BAYLY, Sole Agent for Swiss Clock and Novelty Company, 85, High-street, Kingsland, London (one minute from Dalston Junction, and next door to London and County Bank). Established same address fifteen years. Agents wanted in every town for sale of our Clocks.

£150 IN GOLD FREE

We offer the above amount of money and TEN GOLD WATCHES FREE to the first 107 persons answering the following Bible question: WHAT KING IN THE BIBLE IS MENTIONED AS HAVING LAIN ON AN IRON BEDSTEAD? Mention the BOOK, CHAPTER AND VERSE.

The First person answering this question correctly, on or before July 25th, will receive £20 in gold. If we receive more than one correct answer, the Second will receive £18; the Third, £15; the Fourth, £12; the Fifth, £10; the Sixth, £8; the Seventh, £6; Eighth, £5; Ninth, £3; Tenth, £2; Eleventh, £1; Ten Gold Watches to the next ten correct answers, and 10s. each to the next One Hundred people answering it correctly. If you are not the first, remember that you may be the second or third, so you stand a good chance for a large prize. Each competitor must, in every case, send 2s. for a six months', or 4s. for one year's subscription to THE HOUSEHOLD JOURNAL, with their answer. This journal is an illustrated magazine, and is one of the most Beautiful and Popular of the Day. It contains Twenty Large Pages, and has an elegantly engraved, illustrated, and tinted Cover. It is replete with beautiful illustrations and choice literature. No expense is spared to make this publication one of the finest in the world.

The regular subscription price of the Journal is 4s. per year, so you pay nothing additional for the privilege of competing for one of the above prizes. The money will be sent to the successful ones. The names of those who obtain prizes will be given in the paper. Send your answer at once. Don't wait. Send money by Registered Letter or P.O. Postage Stamps taken. Sample copy, 4d. Address—

THE HOUSEHOLD JOURNAL,
H. C. EDWARDS, Manager, 31, Bouverie Street, Fleet St, London, E.C

CURE OF DEAFNESS.

NOISES IN THE EARS.

REV. E. J. SILVERTON, Specialist for the CURE of DISEASES of the EAR, invites sufferers to send for his treatise, a work showing the nature of the disease and the means of cure. 275th thousand. Post free six stamps. A letter of advice will be sent with the book, without further charge, to all persons who send a statement of their case. The treatment is frequently very rapid in restoring the hearing power or removing other aural troubles. Patients are not required to leave business or home, as the system adopted by Mr. Silverton gives no pain or inconvenience. Thousands of persons are thus successfully treated. Hearing has been given where none previously existed, and speech has followed as a result. One lady was cured at the age of 90, and another after 40 years' deafness. In cases of offensive discharge from the ears the treatment is most successful, curing after many years' standing. Nervous and throat deafness is also rapidly relieved. If deafness is allowed to remain in young people, loss of speech is likely to follow: hence the importance of immediate and successful treatment. Those who suffer with noises in the ears will find in this remedy the means of cure. It is the height of folly to neglect the first symptoms of aural troubles. Mr. Silverton's celebrated ear trumpets, invisible drums, and sound conductors may be seen and tested at his consulting rooms. Instruments and remedies to suit all. None should despair.—Address: Rev. E. J. Silverton, 16 to 19, Imperial Buildings, Ludgate Circus, London, E.C.

N.B.—Mr. Silverton may be consulted personally during the present month each day from 11 to 2. Saturdays excepted.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, JUNE* 19, 1885.

## GAS AND ITS APPLICATIONS.

THE meeting of the Gas Institute last week, and the action of the Council of the Parkes Museum in promoting a series of exhibitions of apparatus for utilising gas in cooking, heating, lighting, &c., both afford evidence of the greater interest which is now taken in gas by those immediately concerned in its manufacture and by the general public. The success of the electric light, limited as it may be in this country, is still sufficient to teach gas managers that there is at least a possibility of considerable development, and though they know very well that they have nothing really to fear from the competition of electricity, it is certain that those interested in gas have of late years exhibited a little more desire for progress than could have been discovered before the electric light demonstrated its capability of becoming a formidable rival to gas as the illuminant of the public streets and large buildings. The gasmen know now that they are quite safe, so long as it is a question of price; but expense is not always a complete measure of the demand for an article, and if electricity does cost more than gas as an illuminating agent, it possesses certain advantages which in many cases will turn the scale in its favour. Alderman Bailey, who welcomed the Gas Institute to Manchester, told the members that he did not care so much for cheap gas: he would prefer to pay more for a better article, and he unquestionably spoke for a large number of consumers who want the best and purest illuminant that can be provided. The question, however, is, Can gas be materially improved as an illuminating agent at a moderate increase in price?—and the answer may be found in the address of the president, Mr. T. Newbigging, C.E., who intimated clearly that managers were looking to the application of gas for cooking, heating, and motive power for their future triumphs. He knows that, as an illuminating agent, gas has nearly reached its possible perfection—that very little more can be done to improve its light-giving power, while a wider field of usefulness is at present comparatively unworked. As it is, the Manchester gas is superior to that supplied to London, for it has an average illuminating power of 20 candles, and there is no "company" to adulterate it with the view of annoying consumers. Gas of higher illuminating power can scarcely be wanted, so that it would appear Alderman Bailey is not satisfied with the purity of the illuminating agent supplied to him, and would be glad to pay more money to have his gas entirely free from sulphur. It must be confessed that there is room for improvement in that direction, for even in the metropolis the gas frequently contains 13 grains of sulphur per 100 cubic feet. It is true that the limit allowed by Act of Parliament is 22 grains per 100 feet, and 4 grains of ammonia in the same quantity. It is well known that the manager is anxious to get all the ammonia possible out of his gas, and as a matter of fact in London he does not leave so much as half a grain in 100 cubic feet. It would be unfair to say that manufacturers of gas are not so anxious about eliminating sulphur, which is valueless, as they are in seizing ammonia; but admitting the difficulty of entirely purifying the gas from sulphur, we might fairly ask for something less than 13 grains per 100 feet. Mr. Newbigging told his hearers that the "resources of civilisation and science are far from being exhausted as regards the developments which may yet take place in gasworks"; but that was in connection with coal-tar products, and the probable increase in the quantity of ammonia seized and converted into liquor—viz., instead of only 30lb. of sulphate of ammonia per ton of coal, the president looks forward to 75lb. and 95lb. of sulphate. To obtain that, much of the coke must be utilised, unless some cheaper means of producing hydrogen than by the decomposition of steam is discovered. Most persons will be surprised to learn, from the carefully prepared returns forwarded to the president of the Gas Institute, that only about 6 per cent. of the total product of the gasworks of the United Kingdom is used for purposes other than lighting, though, making a select list of those districts where special efforts are employed to induce the public to utilise gas for heating and cooking purposes, the proportion rises to 14 per cent. The town of Northampton, it appears, has taken the lead in utilising gas for heating and other purposes connected with the arts, for out of a total consumption of 215 million feet, 90 million are used for purposes other than lighting—viz., in 250 gas-fires, 2,700 cooking and boiling apparatus, 400 small stoves used by shoemakers for heating finishing tools, and 40 gas-engines. Mr. Newbigging is not sanguine that the gas-engine will eventually supplant the steam-engine; but he evidently does look forward to the time when a more extended use of gas will solve the smoke problem, or at least reduce the nuisance within the limits of toleration. There is no reason why coal should be used on furnace fires when coke would do at least as well, and the gas makers would be glad to extract the gas, the tar, and the ammonia, and provide work for their plant which, at certain seasons of the year, is necessarily idle for many hours out of the twenty-four. At the Colne Vale Works, Longwood, near Huddersfield, the much-needed reform is being carried out on a small scale, and it is found that the coke from a ton of bituminous coal will do as much work in the furnace of a Lancashire boiler as the ton of coal would have done: if the grate is specially constructed for burning coke the latter will do 15 per cent. more than the coal. Those statements are made on the authority of the manager of the works, and it is obvious that if the coke obtained from a ton of coal will do the work of the coal itself under a steam boiler, then the gas, and the tar, and the ammonia are so much valuable materials wilfully wasted. We are not prepared to accept the statements as data to be relied upon in all conditions; but it is easy to understand that if the coal now sent up the London chimneys were to be taken to the gasworks first, and then distributed as gas and coke, it would be equally beneficial both to the pockets and the lungs of the residents. The president of the Gas Institute denies that the recent advent of the electric light has had the effect of infusing new life into the action of the gas authorities of the kingdom; but he acknowledges that the introduction of the electric light has led to a demand on the part of the public for more light. We are not concerned to split this difference: the important fact is that the gasmen have now an opportunity of showing what they can do, and if they were at once to boldly demand liberty to put down another series of mains, in order to supply cheap heating gas, they would, we believe, meet with little opposition. Mr. Frederick Siemens has taken up this idea of his more distinguished brother, the late Sir W. Siemens, and while endeavouring to introduce his new regenerative gaslight apparatus, which is designed to distribute the light while concealing it from direct vision, is not unmindful of the utilisation of gas for heating and cooking purposes. In this latter connection no one has done more than Mr. Fletcher, of Warrington, whose ingenious contrivances are highly esteemed by all who have tried them. There seems no reason why, with gas as the medium, we should not obtain heat and light at the same time under suitable conditions, and it is certain that as soon as the demand arises there are plenty of inventors ready to supply it. If Mr. F. Siemens' stove and his burner are really all that is claimed, they will go a long way to meet the wants of the public, especially as his lamp is also a ventilating agent, and the stove is more economical than the open coal fire, which is decidedly wasteful, but to English people very cheering. It must not be forgotten that the larger the quantity of gas produced by any given plant, the cheaper the rate at which it can be supplied, and it also follows that if gas companies can themselves utilise all the products of their distillation of coal the greater the advantage to the public. For instance, Mr. J. Hepworth, of Carlisle, suggests that gas companies should make sulphuric acid in their works and use it for converting the ammoniacal liquor into sulphate of ammonia. The spent oxide of iron, when discarded from the gasworks, contains on the average 50 per cent. of sulphur, and there is no doubt that it could be more economically utilised *in situ* than in distant works. There is a tendency amongst gas companies to thoroughly exhaust the coal on their premises, to utilise every by-product which can be turned to account, and to discard only the rubbish—rubbish because no use has yet been found for it; and there seems no reason why, as manufacturers, they should not get all that is possible out of the crude material they import. The utilisation of gas for motive-power purposes has recently met with a serious check, for it has been demonstrated that a gas suitable for exploding in engines can be more cheaply made by decomposing steam; and though for convenience small power-users will still employ the gas supplied for illuminating purposes, with the increase in the number of gas-engines, there will not be a proportionate increase in the consumption of coal-gas, for those who have sufficient space will erect the Dowson, the Wilson, or the Strong apparatus for producing a mixture of hydrogen and carbonic oxide by passing steam through incandescent coke. We have already described the Dowson process, which yields a suitable gas at the rate of about 3d. per 1,000 cubic feet. A larger quantity of that is required than is the case with coal-gas; but an expenditure of about 1s. enables the same quantity of work to be done as can be accomplished with 1,000 cubic feet of the richest coal-gas. As a matter of fact the Dowson gas gives one indicated horse-power for every 1·2lb. of coal, while the best steam engines require at least 1·5lb., and can do with so small a quantity only when the steam is passed through three cylinders. For that reason gas managers have ceased to look for any very great demand from the users of power; but they are wisely turning their attention to the development of cooking and heating applications, though even in those fields they have a formidable opponent in the so-called "water gas," which in Germany is now made by the aid of refuse coal, and is utilised for illuminating purposes by rendering wires and rods of magnesia incandescent. Water-gas, however, is not yet laid on and supplied through a service of pipes, and it is doubtful if it ever will be, at least in towns, for the absence of any smell is a decided objection to its use for ordinary domestic purposes, on account of the difficulty of discovering any leakage. In the United States that danger is surmounted by carburetting the gas with petroleum, which not only renders it illuminating, but also

VOL. XLI.—NO. 1,056.

imparts to it what may be termed a safety odour. Producer gas has a future before it in connection with gas-engines, but where steam boilers are used it will probably be found more economical to burn coke. Altogether it may be said that the importance of gas, whether "coal" or "water," is at last beginning to be recognised by the public, and we may probably yet see London without its smoky pall even in November.

## REVIEWS.

*Ballooning: a Concise Sketch of its History and Principles.* By G. MAY. London: Symons and Co.

THIS concise little sketch of the art of aërostatics is published at an opportune time—just when attention has been directed to the subject by the alleged successes of the French experts and an exhibition of aëronautics is to be held at the Alexandra Palace. Mr. May gives us an historical *résumé* of the earlier attempts at aërial navigation, and enters into more detail in connection with the latest exploits. So far his work will be useful to those who desire to acquaint themselves with what has already been done, but we fail to find that the author has any practical suggestions to make. He thinks that it would be "venturesome to assert that aërial navigation has no future, looking to what it has accomplished during the past century," which is certainly very little indeed; but we are quite ready to agree with the author that "it is quite within the scope of discovery to contrive some appliance partly to effect a more practical solution of the difficult problem of balloon steering." Aërial navigation is at present a misnomer, for so long as it is necessary to overcome the effect of gravity by means of a huge vessel of gas to give ascensional power and support in the air, not much will be done in the way of steering or pursuing a definite course. It may be possible by the aid of sails, rudders, propellers, &c., to exercise some little influence on the direction taken by a balloon; but, after all, it must go the way the wind blows it. Most people will agree with Mr. May when he says that "manifestly, aërial travelling will never be cheaper than by railway or steamboat." The book, which is issued in the "Specialist's Series," edited by Dr. Paget Higgs, contains illustrations of Giffard's balloon, Tissandier's device, with the propelling apparatus and the plant for making hydrogen, and the more recent device of Renard and Krebs. It will be very useful to those who want to know what has already been done, and have no time to hunt up the records.

*Pattern Making.* By A FOREMAN PATTERN MAKER. London: Crosby Lockwood and Co.

IT is not necessary to do much more than state that this volume is mainly a reprint of the articles which have recently appeared in these columns. Our readers have been able to form their own opinions of their practical utility, and many of them will be glad to have the matter in the handy form presented to us by Messrs. Lockwood. The articles have, we need scarcely say, been revised and corrected, have been expanded by the incorporation of new matter, additional sketches, and useful tables, while a copious index will now afford the means of readily referring to any point on which information is required. The volume is dedicated to the author's fellow workmen, to draughtsmen who have not had a practical training in the shops, to pupils, managers, and employers—in short, to all who seek more than a mere smattering of knowledge and desire to learn not only the best practices, but also why they are the best. More than 370 illustrations help to explain the text, which is, however, always clear and explicit, thus rendering the work an excellent vade-mecum for the apprentice who desires to become master of his trade.

*The Chemistry of Cookery.* By W. MATTIEU WILLIAMS. London: Chatto and Windus.

BY the noble army of cooks, if they condescend to read this work, many of the opinions expressed by Mr. Mattieu Williams will be denounced as rank heresy; but the author has made almost a life-long study of the subject, and deals with the science of cookery as opposed to the mystery of the cuisine. It is nearly thirty years ago since the author first touched on the subject in lectures delivered at the then infant Birmingham and Midland Institute, and in that interval little if anything has been done by anyone else in working out the chemistry of cookery. The "chemistry of food" has been dealt with often enough, but the chemistry of cookery is of as much importance, and those who will read what Mr. Mattieu Williams has to say will find a good deal of suggestive material for further investigation. For instance, cheese, as we suppose every one knows, contains weight for weight more nutritious material than any other food ordinarily obtainable; but, as Mr. Williams says, its cookery is singularly neglected, and is practically an unknown art in this country, while all that is required to render cheese, next to bread, the staple food of Britons is scientific cookery. We will quote one of the recipes given by the author, because it contains an important note which it is necessary to observe if cheese is made a staple food. Take a ¼lb. of grated cheese; add to it a gill of milk, in which is dissolved as much powdered bicarbonate of potash as will stand upon a threepenny piece. Heat carefully until the cheese is completely dissolved; then beat up three eggs, yolks and whites together, and add to this solution, stirring the whole. Put a little butter into a shallow dish or tray that will bear heating, and when the butter frizzles pour the mixture in and bake or fry until it is nearly solidified. Mustard, pepper, &c., are to be added to the solution of cheese, "according to taste," and Mr. Williams says that if a cheaper dish is desired the proportion of cheese to eggs may be increased. The carbonate of potash is the novelty in this recipe, and its use is advocated because it effects a better solution of the casein by neutralising the free lactic acid in the milk and any remaining in the cheese; also, more importantly, because it restores to the cheese the salts of potash which were left behind in the whey. Milk is not necessary, as the cheese may be dissolved in water by grating or thinly slicing it into its own bulk of water in which carbonate of potash has been dissolved at the rate of about a quarter of an ounce to a pound of cheese. This solution of cheese is to be added to porridge, to mashed baked potatoes, to hasty pudding, to rice, and so on. The chapter on Count Rumford's Cookery and cheap dinners should be studied carefully in these times, but in all the nineteen chapters into which the work is divided there is much both to interest and to instruct the general reader, while deserving the attention of the "dietetic reformer."

*The Moon and the Weather.* By WALTER L. BROWNE. London; Baillière, Tindall, and Cox.

IN the preface to this work the author says that "the lunar theory is often spoken of, but no attempt is made to demonstrate that theory; not because such demonstration is impossible, for it can be demonstrated, and its truth decided in the most positive manner." The reason why the lunar theory is not demonstrated we are left to guess; but we have a number of assertions, a remarkable specimen being the statement that "the weather, in its larger and minute variations, must be governed by law, or there can be no such thing as a science." The author says that this law is "periodical and recurring"; but all we know about it is that if certain causes are acting certain effects will follow. There is no periodicity about them, except, perhaps, in given localities, so far as the major effects are concerned. Local conditions have indisputably more effect on weather and climate than any supposed lunar influences; and, as a matter of fact, the author's opening statement puts the case clearly, for he writes, "It has been asserted over and over again by most scientific men of the present day that the moon has no influence on the weather"—an assertion which is either incorrect or true; but if incorrect it should be an easy matter to demonstrate it. We have been unable to find any demonstration of lunar influence on weather in these pages, and we quite agree with the author when he says that "the weather enigma is yet an unsolved problem." His work will, however, interest a limited class, and more especially those who have rival hypotheses.

*Supplement to "Euclid and his Modern Rivals."* By C. L. DODGSON. London: Macmillan and Co.

WE reviewed Mr. Dodgson's "Euclid and his Modern Rivals" on p. 174, Vol. XXIX., and this supplement will be read with renewed interest, for so far none of the numerous writers on geometry has gained much *kudos* in the controversy. The supplement, which is paged continuously with the work, is a criticism, in the form of a dialogue between "Niemand" and "Minos," of Professor Henrici's "Elementary Geometry," and it is at once interesting and amusing, for Mr. Dodgson is a master of his subject, and a very able defender of Euclid. Prof. Sylvester was, we believe, the first to suggest that Euclid ought to be banished from our schools, and, as we know, books on geometry have been produced by the score; but the time-honoured work of the Alexandrian Geometer, with all its faults—if faults they are—still holds its own, while those of his modern rivals suffer considerably at the hands of this genial if caustic critic.

We have also received *The Works' Manager's Handbook*, by WALTER S. HUTTON (London: Crosby Lockwood and Co.), a valuable book of modern rules, tables, and data, which has rapidly reached a second edition. Some new matter has been added, and the errors of the first edition, almost unavoidable in a work of such magnitude, have been corrected. It will fill a useful place in the library of every engineering works. *Technological Dictionary*, Part II., German—English, by F. J. WERSHOVEN, D.Sc. (London: Symons and Co.), is a handy vocabulary of technical terms used in the physical, mechanical, and chemical sciences.——*German Grammar and Reader*, by EMIL BEYER (London: D. Nutt), is written expressly for the use of science students and those who have little time to work through the more elaborate works; the most important features of the new German spelling are pointed out, and it may be recommended to those who are desirous of rapidly acquiring a sufficient acquaintance with the principles of the German language to enable them to read scientific treatises with comparative ease.——*Practical Problems and Lines for Working Drawings* (Manchester: Abel Heywood and Son), is a volume embracing within its limits a variety of problems, rules, and calculations which may be of service in the routine of the workshop.——*The Magic Lantern Manual*, by W. J. CHADWICK (London: Frederick Warne and Co.), is the second edition of a little work which should be in the library of all users of the lantern.——*The Winds*, by W. Leighton Jordan (London: David Bogue), is the third edition, revised and abridged, of a little work which forms the third and fourth chapters of the author's "New Principles of Natural Philosophy."——*William Hedley, the Inventor of Railway Locomotion* (Crosby Lockwood and Co.), is the third edition, with additional matter, of Mr. M. Archer's brochure, in which he shows that William Hedley can claim to be the first to make the locomotive a practical success.——*Of the Origin and Reproduction of Animal and Vegetable Life on our Globe*, by Thomas Spencer, F.C.S., F.R.M.S., &c. (London: Effingham Wilson), is an attempt to show that suboxide of iron causes the formation of carbonic acid from its elements, and is the origin of animal and vegetable life.——*On the Principles of Electric Lighting*, by Sydney F. Walker, M.S.T.E. and E. (Newcastle-on-Tyne: Andrew Reid), is a paper specially written for engineers, and gives all the information needed by practical men to apply the principles set forth. It is freely illustrated with a number of useful plates, and will be found valuable by all engaged in electric lighting.——*The Theory and Action of the Steam Engine*, by W. H. Northcott (Cassell and Co.), is the fourth edition of a deservedly appreciated treatise on the steam-engine specially written for practical men.——*Walks in Epping Forest*, edited by Percy Lindley (London: 123, 125, Fleet-street, E.C.), is a well-written, beautifully-illustrated guide to Epping Forest, useful alike to the pedestrian and the cyclist, and also the horseman. All the principal points are well described and mostly illustrated, and there is a chapter on the fauna and flora of the forest by A. H. Wall and the editor, and one on its geology by Horace B. Woodward, F.G.S. Those who wish to pay a visit to Epping Forest should procure this guide, read it, and take it with them.

We have also to acknowledge *Twenty Years with the Indicator*, by Thos. Pray, Jun. (New York: Wiley and Sons; London: E. and F. N. Spon); *Locomotive Engine Running and Management*, by Angus Sinclair (New York: Wiley and Sons; London: Trubner); *Gas Engines*, by William Macgregor (London: Symons and Co); and *The Structure of the Wool Fibre*, by F. H. Bowman, D.Sc. (Manchester: Palmer and Howe), all of which require a more lengthy notice than can be given under this heading.

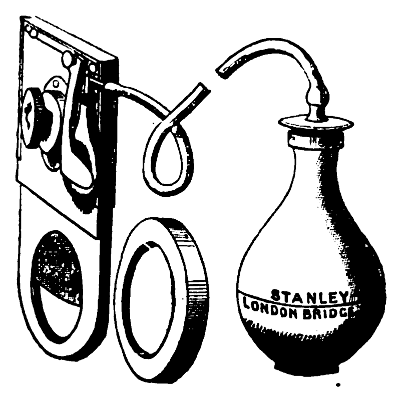
## THE INTERNATIONAL INVENTIONS EXHIBITION.—VII.

### Machine Tools and Machinery.

For some reason or other machine tools and machinery are placed in Group X., and Group XI. is supposed to be devoted to hydraulic machines, presses, machines for raising heavy weights, &c. So far as the visitor is concerned, no particular harm is done, as the two groups are located close together, and an inspection of the stands will show that there is very little difference in the nature of the exhibits, which are mixed, as will be seen further on. Perhaps the most remarkable "group" in the whole exhibition is No. XII., which is supposed to be devoted to the elements of machines, and which has less than half a dozen exhibits, two of those being improvements in lock-nuts! An exhibit which really does belong to "elements of machines"—the collection of educational models shown by Mr. J. Rigg—is placed amongst the philosophical instruments in Group XXVIII. There may be some explanation of so eccentric an arrangement, which helps to increase the bulk of the catalogue without any corresponding advantage to either visitors or exhibitors. We will deal with the three groups as one. Judged by the space it occupies, the cask-making machinery of Ransome and Co. is an important exhibit: it certainly attracts a crowd, but is scarcely a novelty, though very interesting. They also show samples of their steam tree-feller, consisting of a saw attached to the piston-rod of a steam cylinder, a device also exhibited by Worssam and Co. The group contains a number of machines which it is impossible to describe without engravings, and also many which, while of great value, are not of much interest to the general body of readers. Greenwood and Batley, of Leeds, for instance, have an interesting collection of machine tools, including Parker's automatic screw-making machine, one or two milling machines, and an automatic grinding lathe for backing off twist drills, in which a little emery wheel clears away metal behind the cutting edge, thus enabling the drill to run freely in the hole with the minimum of friction. Emery-wheels of various sizes are shown by several makers, notably by A. H. Bateman, East Greenwich, who also exhibits specimens of work done by them, such as chilled cast-iron rollers, loco. slide-bars, and Nordenfelt bullets. The famous Tanite wheels are exhibited at the stand of Selig, Sonnenthal, and Co., who have a collection of useful appliances, including patent braiding and winding machines for covering wire, and their patent self-acting band-saw filing machine, which sharpens at the rate of 80 teeth per minute. The file is carried by an arm receiving motion from a crank on the driving shaft, which arm works in a guide readily adjustable for different sizes of saw. The saw is pushed forward by a little pawl which drops behind the front edge of a tooth and, receiving motion from a kind of eccentric, advances the teeth as fast as the file can accomplish the work. A fine screw-cutting lathe with turret head is also shown by this firm. Mr. J. H. Evans, of Wardour-street, exhibits three lathes, one on a wooden frame, and a collection of the ornamental turning appliances which he described in Vol. XXXIII., and subsequently. He also exhibits a number of specimens of ornamental turning in ivory and hard wood, many of which will be recognised by our readers. Messrs. Holtzapffel, of Charing Cross, exhibit fine specimens of their productions in lathes and appliances, and a novelty in the shape of a patent rose chuck, which will probably be described elsewhere in these columns before long. The collection of specimens of ornamental turning shown by this firm contains a number of objects which will be recognised by those who have seen Vol. V. of Holtzapffel's "Turning and Mechanical Manipulation." Pfeil and Co., of St. John-street, show a vertical planing attachment on a 6in. lathe, in which the motion of the tool is automatically reversed. The tool-holder has a branch working on a guide and striking against studs screwed to the guide, which at its upper portion is connected to a weighted crank which puts a movable pinion into gear alternately with two bevel wheels, and so reverses the motion of the screw carrying the tool-holder. The studs being movable, the length of cut can be readily adjusted within the limits of the machine. Near the entrance to the West Gallery there is a case of specimens of the Maindy steel, made by Jenkins Bros. and Co., of Cardiff, which is rapidly coming into favour as a tool steel in preference to the best specimens from Sheffield. Close by is a model of Stewart's patent "rapid" cupola, exhibited by Machell and Co., which, according to several practical trials, yields a ton of iron for 1cwt. of coke. The "Eclipse" jaw-chuck of Storey and Phillips, 62, Holborn Viaduct, can be here seen in some variety and in large sizes. We illustrated and described it on page 192, last volume. Mr. R. K. Jones, of Birkenhead, exhibits some improvements in braces with variable automatic feed, and tools for cutting out circular and elliptical holes in iron plates—e.g., for ships' cabin lights. Mr. Valda, of Chiswick, exhibits an arrangement for preventing the wear of plane irons on the return stroke, which consists of a roller in the front foot of the plane, pressed outwards by a spring, which thus lifts the body of the plane as the pressure is taken off in the return stroke. Mr. Marsden, of Sheffield, exhibits his apparatus for turning shafting, and his patent surface grinding and polishing machine, which consists of a ring holding segmental pieces of grit stone or emery composition, which is revolved against the face of the work. Planing is said to be not merely superseded but surpassed by the use of this machine. Perhaps the most interesting exhibit in Group X. is the stone-working machinery of Brunton and Trier, of Westminster. The ingenious application of a hollow cone of thin steel as a cutter for truing the faces of grindstones has already been mentioned in our columns; but the manner in which it is set, with sighting arrangements for adjusting it to put a perfectly true face on the stone, will commend this invention to those who have tools which require sharpening frequently. Their lathe for turning pillars of stone has a solid cutter of the disc pattern, but for the softer kinds the cutter is usually of chilled cast iron in the form of a hollow cone, the working edge being always the hardened surface. The most interesting machine in the exhibit of Messrs. Brunton and Trier is, however, the new moulding machine, provided with horizontal and vertical chucks, each carrying four cutters, so arranged that the cutters on the separate chucks clear one another and rapidly cut the moulding on the stone. The cutters fixed are of the cone type, which seems to be just what is wanted for working all the softer kinds of stone, including grit and sandstone. Stauffer's lubricator, which was first described in our columns on p. 249, Vol. XXVIII., and subsequently at greater length in Vol. XXXIX., p. 314, is also exhibited by Brunton and Trier, who find it very useful in connection with their stone-working machinery, as it is entirely closed, and the adhesive nature of the lubricant as it oozes out at the ends of the journals seizes on the flying dust from the stone and prevents it from finding its way into the bearings. Stauffer's lubricator is to be seen on many of the running machines in the exhibition. A novelty exhibited by Brunton and Trier is found in Kaiser's counter, an ingenious device in which all the wheels are locked and cannot move until they are compelled by the revolution of those indicating the smaller numbers. The wheels are all of the same size, and have a gap in the rim, in which a toothed wheel and a sort of pawl engage in such a manner that it is impossible for them to slip, while they are compelled to advance one division as the preceding wheel completes a revolution. This counter is, we understand, not yet in the market. Watts and Co., of Bristol, exhibit a double band-sawing machine, which takes two cuts at the same time in a plank, one saw being placed in advance and to one side of the other. One driving pulley works both saws, thus insuring uniform speed. A very useful general band-saw is shown by Worssam and Co., of Chelsea, in which the standard is made to cant by means of a rack operated by a worm and wheel. The centre of motion, or axis of the canting standard, is that point of the table where the saw passes through, and the saw pulleys being carried by the standard, the angle of the saw can be varied even while at work. All sorts of irregular shaped curves can be cut by this machine. Davis and Son, of Derby, exhibit Hamilton's hand-feed planing and jointing machine, the principal feature of which is the angling table on the feed side, which enables the operator either to cut wood unequally thick transversely, as is frequently required in pattern making, or to trim wood of unequal thickness to uniformity. At Chubb and Sons' stand there is a circular saw cutting through blocks of steel, the saw being lubricated by revolving through a tank containing soap and water. A useful slotting machine is shown by J. Spencer and Co., of Keighley, for either hand or steam power. It can be fixed on the bench or in the vice, or kept on its special standard, while it will cut a keyway perfectly parallel or deeper at one end than the other. An index at one end shows at a glance whether the machine is set for cutting taper or parallel slots, and an ingenious arrangement of a wedge keeps the cutter from the work on the return stroke, while forcing it up to the face on the effective stroke. The "Keyseater" is a machine shown by Harpers, Limited, of Aberdeen, specially designed for cutting keyseats in wheels, &c., however large their diameter. The machine is arranged in a vertical standard, with a table on which the pulley or the work is bolted. The cutter or saw is driven by the shaft in the base of the standard, and, being kept to its work by a hand lever, any desired taper can be given to the slot without adjusting the wheel on the table. Mr. Taylor, of Birmingham, exhibits a collection of his tool-holders, including the screw-cutter, which has a barrel with a swivelling movement, thus enabling V-threads to be cut either right or left hand of almost any diameter with a single cutter. Mr. Taylor also shows a useful parallel grip vice, in which the loose jaw is free to slide backwards and forwards in the slot, while the grip plate catches in the rack and carries the screw by which the jaw is tightened on the work. Mr. Snowdon, of Deronda-road, S.E., exhibits a model of his boring, recessing, and screw-cutting apparatus, which has been used with much satisfaction in boring the holes for fixing armour plates on the *Conqueror* and the *Rodney*. Without illustrations it is useless to attempt to describe this apparatus; but it may be mentioned that it contains a special form of thread-cutting spindle, with an expanding cutter for recessing the bottom of a hole. An automatic index shows the operator the amount of cut at each revolution, and also when the full thread has been completed. Another very interesting exhibit in Group X. is the sheet casks of Mr. F. Andrew, of Botolph-lane, E.C. These are intended for the packing of fish and sundry other articles, and are made either as casks or what may be termed cask-crates. The staves are secured to bands of hoop iron, and are forced into position and headed in a machine. When they have served their purpose as casks they can be opened out into "sheets," and thus occupy little space as returned empties. By attaching the staves to the iron bands at intervals a sort of crate is formed. The art of embossing tinware is shown at the stand of Mr. W. Newell, of Birmingham. The die is carried in a chuck, and the disc of tin-plate, previously stamped to shape, is placed over the die and held by little clips. A burnishing tool is then brought with considerable pressure against the tin-plate, which is at the same time spun into shape and forced into the lines of the die. Messrs. Mintons, of Stoke-upon-Trent, exhibit their apparatus for utilising compressed air in the manufacture of pottery, and the pneumatic arrangement for drawing off the powdered flint as it is ground off the china biscuit ware. The ingenious machinery for packing tobacco and making cigarettes, exhibited by Sales, Pollard, and Co., of Farringdon-road, E.C., will attract the attention of visitors. The cigarette machine is Leblond's patent, and is automatic in its action, the attendant having only to supply the endless band working in a trough with the tobacco. The paper is in the form of a reel at the top of the machine, is cut off to the required length, rolled up into tubes, and passed down a sort of step ladder until it reaches the level of the tobacco trough. Here it finds a portion of the tobacco cut off from the trough, which is immediately driven into it by a plunger, and the cigarette is tumbled off into a receptacle. It is stated that this machine makes cigarettes at the rate of 20,000 a day. Another automatic machine, which is sure to attract groups of admiring visitors, is the paper bagmaking machine exhibited by Mr. Bumsted, of Hednesford. In this the paper is cut from a roll, and pasted and folded entirely by the action of mechanical fingers, the bags being made either square or plain bottom as required, and delivered in a pressed form ready for packing. Visitors to this portion of the exhibition will not fail to inspect the pulsometers, several of which are shown in action, nor the hydraulic machines for riveting &c.; but the engineer or mechanic who stops to look at Tweddell's hydraulic riveters, shown by Fielding and Platt, of Gloucester, will be attracted by a model of a high-speed rotary engine, which is also shown driving a dynamo for electric lighting. This is the Fielding high-speed engine, a device which fairly baffles description. It has four "cylinders," which are not cylinders, but circular cavities, and it is practically a universal joint connecting two shafts which form an angle of about 157 degrees. Two cylinders are mounted on a chair-coupling on each shaft, and the four pistons are carried on a gimbal ring. The engine is compound in the ordinary sense, and is so remarkably compound besides that nothing but an examination of the working model which Messrs. Fielding and Platt have provided will serve to explain the action. The Davey "domestic motor," or safety engine, is exhibited by Hathorn, Davey, and Co., of Leeds, and will doubtless attract the attention of those of our readers who were interested in a recent discussion. The principle of the engine is the production of a vacuum, so that there is no pressure and no risk of explosion whatever. The exhibits of Price's Patent Candle Co. and of J. and J. C. Field will also attract groups of the curious to witness the machines braiding the wicks, and the operations of the lathe employed to turn a spiral on the candles. In this Group (XI.) the chief attractions to the engineer and mechanic are a steam hammer, shown by Glossop and Stacey, of Sheffield, which is self-acting, or controlled by hand, and will give a dead blow for stamping purposes, and Robson's patent gas hammer, exhibited by Tangye Brothers. The cylinder is placed over the anvil as usual; but it contains two pistons, the upper one working in the top half of the cylinder and having the duty of charging the cylinder with a mixture of gas and air, which is drawn in between the two pistons and exploded. The hammer is drawn back by two spiral springs arranged in casings each side of the cylinder, and connected by chains to a crosshead on the rod of the lower, or hammer, piston. Once started, the action is automatic, the admission valve being operated by a cam motion from the flywheel shaft. The force of the blows can be regulated by increasing or diminishing the quantity of explosive mixture admitted. Besides the gas hammer, Messrs. Tangye exhibit a collection of the various machines and appliances made by them, including pumps and hydraulic jacks, electric governors, and self-sustaining blocks. In referring to the last-named device we must mention the sheave blocks of Swalwell and Moore, of Acre-street, Battersea, which sustain the load directly the operator ceases to apply power, and enables him to lower it under perfect control by simply pulling the releasing cord. We shall probably describe at greater length these blocks and hoists. A notable exhibit in this group is the Worthington steam-pump, which has recently attracted some attention in this country. The pump chambers and steam cylinders are cast in pairs, and placed in line at opposite ends of the frame. The cylinders have ordinary slide valves which are operated by a vibrating arm on the main rod, the arrangements being such that the valve of one cylinder is shifted by the motion of the piston in the other. In these engines a large and direct water-way is obtained, and the parts are so readily accessible that there is little delay when any portion requires renewal, the parts being interchangeable. The collection of hydraulic machinery compares favourably with other groups in the exhibition, as it is fairly complete and contains examples from nearly all the principal makers. A portion of the group will be found in the east of the Queen's-gate Annexe, where there are several fire-escapes, fire-engines, and sundry other inventions having more or less connection with hydraulic machines.

## SARGEANT'S PATENT DROP-SHUTTER.

ONE of the most remarkable advances of modern photography is the production of highly sensitive dry plates, which permit, with certainty, moving life, forms and objects only dimly lighted, to be represented perfectly. But, in proportion to the sensitiveness of the plates, the difficulty in timing the exposure becomes greater, so that it is a great desideratum to be able to perfectly control the time of the exposure of a plate, upon which the perfection of the photograph almost entirely depends. This desideratum appears to be met in the drop-shutter invented by Mr. W. L. Sargeant, of which the above is an illustration, which has the special merit of being quite under the control of the operator, so that exposures of a quarter of a second may be given, or the exposure may be prolonged for a minute or more, with little change of the parts of the apparatus, the apparatus itself being very small and portable. Thus, for using this shutter for very rapid exposures, the small milled-head screw, shown at the top of the engraving, is drawn out a little, and the large milled-head screw is turned once round, until it *clicks*; it is then set for rapid exposure, and a single pressure of the pneumatic ball opens and closes the shutter in less than a quarter of a second. For longer exposures, the small screw is turned in up to its shoulder, the shutter being again set up by turning the large milled head until it clicks. The exposure will now continue so long as the ball is pressed and close immediately on its being released, so that this shutter answers perfectly for instantaneous or ordinary work, opening and closing without touching the camera to cause vibration—a fruitful source of blurred outlines. This shutter is otherwise especially constructed to avoid vibration, the opening and closing being actuated by the revolution of a single-arm crank, the crank pin moving in a slot which it *fits*, so that, however rapid the motion, the shutter is held firm at all positions. Another feature is that it opens and closes from the bottom, thereby giving the foreground of a landscape slightly longer exposure than the sky, which it requires. Mr. Stanley, of Railway Approach, London Bridge, is the manufacturer.



## THE AMATEUR WORKSHOP.—VIII.

### Planing Machines.—Power Gear (*continued*).

WE will now finish the special subject matter of our last article—the application of spur power gear for driving, and afterwards hasten on, with as little digression as possible, to the completion of the upper portion of the hand machine proper, reserving, perhaps, for a final chapter or two reference to some special pieces of mechanism. I had intended to draw and dimension unequal bevel wheels with their pulleys and bearings like those shown on Fig. 45, p. 46, for attachment to the side of this bed. Such, to be properly described in detail, would delay us another article, and as a good number of my readers will be wanting to see the work growing, I will let it go by.

It is obvious, on an examination of the views given in our last, that the work involved in the introduction of this spur driving-gear is almost enough to put it out of the range of ordinary home workers. Holes have to be bored and bushed, and these must be done in a boring mill, or upon a lathe of 9in. centres, or under a drilling machine capable of drilling 1⅜in. in diameter. But the intended possession of such a machine implies the existence of power to drive it, and presumably also to drill and bore it.

The modifications required in the bed pattern are these: The two brackets B and C, shown in Fig. 16, p. 511, of Vol. XL., are removed altogether, and a boss substituted at *d*; Figs. 68, 69, 70, on page 250, for the tappet lever. A jointed bearing, *e e*, is provided on each side of the lower portion of the bed (Figs. 68, 69, 70, and Fig. 81) to receive the shaft, *a*, while bosses bushed with brass are provided at *f*, *f* and *g* (enlarged in Figs. 82, 83, 84) to carry the spindles *c* and *b*. The angle bracket, *h*, is widened to receive the foot of a small bearing *k* (enlarged in Fig. 85), which takes the overhang of the spindle *b*, while for the overhang of the pulley shaft *a*, a special casting, Fig. 86, is provided to rest upon the floor or other convenient support. The rib F in Fig. 16, p. 511, is removed backwards 1in. (Fig. 68, *i*), to clear wheel C, and for the rocking-shaft of the striking gear a boss is added at each side of the bed at *j j*.

These various bosses are all skewered on, and it would be much the better to cast them all solid and drill their holes clean through at once. But if it is preferred to cut them out to save this labour, a round print 1⅛in. in diameter must be attached to one side only of each, those prints being all on the outside of the bed. The boss *d* for the striking lever need not be printed at all, because the pin is not large. The bearings *e e*, Fig. 81, will be brought up to breadth by pieces fitted on the outside of the fillets, and the bearing part cut out in the pattern itself to 1in. semi-diameter. The extra facing piece *l*, Figs. 68, 69, will be fastened on to the bracketing, and a hollow put behind it to stiffen it. The patterns of the brackets, Figs. 85, 86, with their caps are sufficiently clear from the sketches.

FIG 83

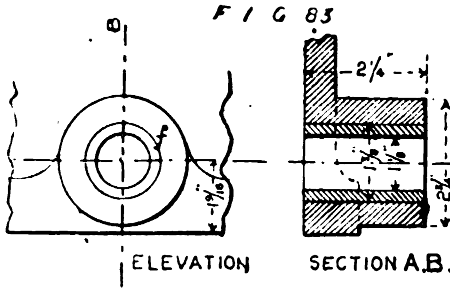


FIG. 84.

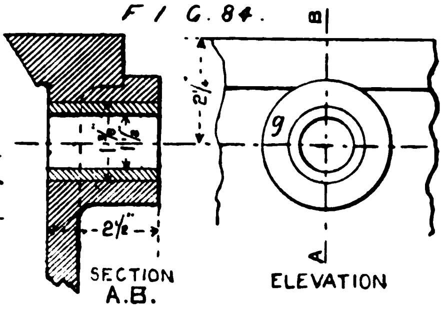

FIG. 87

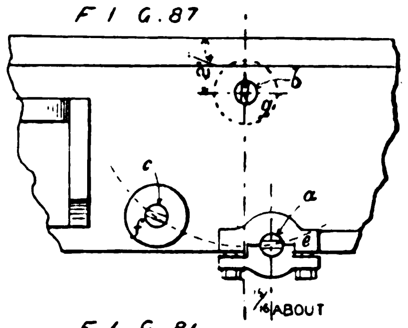

FIG. 82.

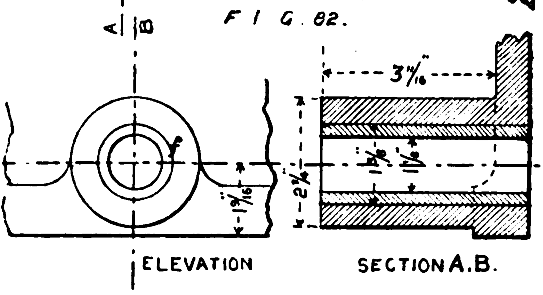

FIG 81

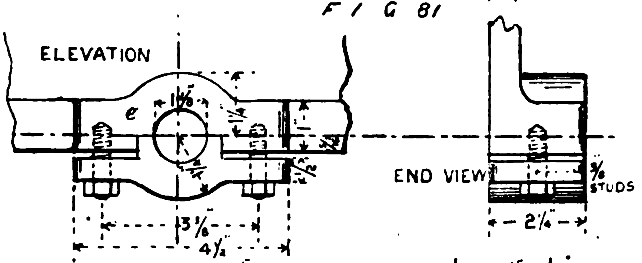

FIG. 85.

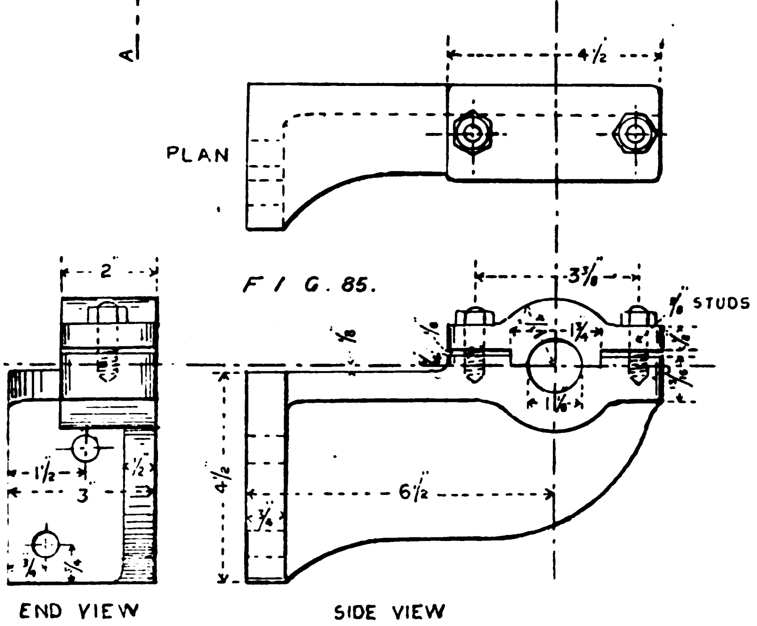

FIG 86

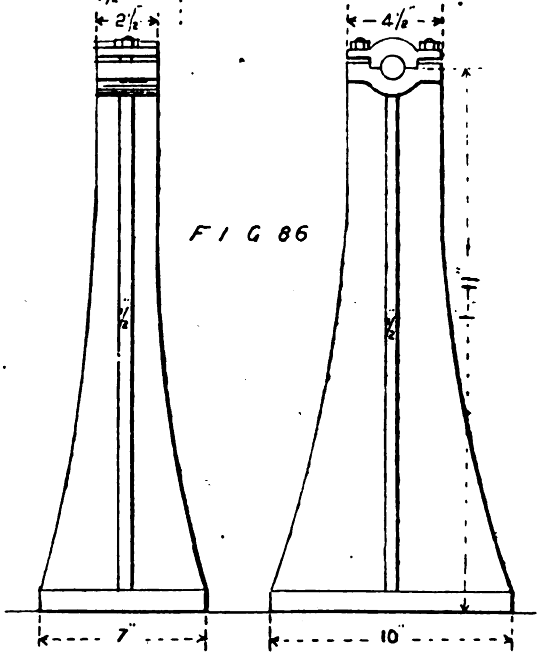


Now, assuming that we have our castings, the first thing is to bore the wheels in the lathe. When bored, it is always the safer way to try the centres of wheels which have to work with one another before marking out their bearing centres. This is necessary because unequal ramming, contraction, and variable qualities of metal produce variation in the sizes of castings moulded from the same pattern. A couple of teeth are chalked, and the positions of the pitch lines scratched on each of these in the particular pair of wheels which have to gear. The pitch lines then being brought to coincide with one another, the centres of the pair are tramelled on a slip of wood driven into the bore of each. These centres are then transferred to the intended centres of the shafts.

Now, in this instance the only centre whose position is of importance is that of the rack pinion spindle *b*, so we make that our starting point. If cored out, all the rough holes must be bridged with a slip of wood, and the caps also must be fitted into their places in the bottom bearings and bolted, and their holes bridged across. The bearing *k*, which carries the overhang of spindle *b*, should be fitted and bolted to its bracket also before being bored.

When all preparations are so made, the two centres—that on the bearing *k* and the one corresponding in the bed—should be marked in position. Carry a square, and scribe a line across the top of the bed, plumb over the cored holes for these rack spindle centres, apportioning to each its share of any variation that exists to one side or the other of the line. Square down on the faces of the bearings, and scribe across on these vertical lines, and at right angles with them, to a distance of 2¼in. from the top of the bed. From the point of intersection as a centre describe a 1⅜in. circle on the boss, and one of 1⅛in. diameter on the bearing, and remove the bearing.

Now trammelling the centres of wheels E and G—about 6⅜in., strike a line from the centres just obtained, cutting the spindle bearings *a* and *c*. Taking the centres of wheels B and C—about 4⅞ and 1/32in., set them on the bearings of spindles *a* and *c*, dividing the difference of inaccuracy of the holes between the two bearings, Fig. 87, and using the square across to maintain the spindles parallel with one another. Scribe 1⅛in. circles on the bottom bearing, and 1⅜in. on the boss bearings. Centre pop all holes.

The neatest tool to employ for boring these would be a boring bar and cutters set in a lathe or boring mill; but in the absence of these appliances a drilling-machine would be used, the bed faces and edges being well tried with a level before beginning to drill. It would be well to take the dirt out of the holes with a common drill in the first place, finishing with a twist-drill or a broach. The bushes (Figs. 82, 83, 84) would be castings made from patterns printed for coring out, and having 1/16in. allowance for turning and boring. They would be bored as well as turned before being driven in, a block of hard wood being interposed between the hammer and the brass to prevent burring over of the edge.

The pulleys will properly be bored first while held in the dogs of the face plate, and then put on an iron mandrel to be turned. Before turning, the outer skin of the rim should be taken off against the grindstone. The rounding will be given with a light feed imparted by the hand to the two slides of the rest—the file removing the tool marks afterwards. It is very possible that the pinion attached to the sleeve-pulley A", Fig. 78, page 250, will be out of truth with it, notwithstanding that the pattern itself is true, owing to inaccurate fitting of the moulding-box in which it happened to be made. This should be tried in the lathe before boring, and if the eccentricity amounts to more than 1 in., the casting should be discarded. Note also that the bosses of these pulleys stand out a bare 1/16in. beyond their edges, to keep those edges from actual contact. The only one which is keyed on is A, a keyway filed in the boss 8 in. by ¼in., and a flat to correspond on the shaft, will be wanted.

Of the three spindles *a b* and *c*, *a* and *c* will be of wrought iron, and *b* of steel. Their lengths are: *a* = 2ft. 4in., *c* = 1ft., 5⅜in., and *d* = 1ft. 2⅜in. A collar, Figs. 68 and 70, is placed on spindle *a*, to keep it steady in the one direction, the bearing, Fig. 86, maintaining it in the other. Oil holes will be drilled in all the bearings and bosses. Before the wheels are put on finally, the spindles should be tried through their bushes from side to side, and any tightness resulting from want of parallelism in the bushes should be eased with a scrape or a half-round fine cut file.

# ELECTRO-MOTIVE ACTION OF ILLUMINATED SELENIUM.

By Dr. Werner Siemens.

THE following is an abstract of a paper read by Dr. Werner Siemens before the Berlin Academy of Sciences on the Fritts' selenium cell, which we described on p. 93 in our issue for April 3.

Mr. Charles E. Fritts, of New York, sent me, early last year, a description of his method in relation to light-sensitive selenium plates, differing from mine in essential features, and accompanied the same by a number of the plates prepared by him. These do not, like mine, consist of parallel platinum wires embedded in a thin body of selenium, but of a thin homogeneous sheet of selenium, which is spread upon a metal plate and, after a subsequent heating—for the conversion of the amorphous into crystalline selenium—is covered over with a fine gold leaf. Mr. Fritts has found that the green light penetrating through the gold leaf by the further passage through the selenium, increases its electrical conductivity. In fact, the conductivity of the selenium plate between the gold leaf and the metallic base-plate is, by the illumination of the gold leaf with direct sunlight falling perpendicularly upon it, increased to the extent, in some of the specimens sent over, of from 20 to 200 times! The effect of illumination by diffused daylight is also greater in Mr. Fritts' constructions than in mine.

One of the plates sent over to me exhibited absolutely no sensitiveness to light; but in place of that it has another most remarkable property, namely, that a galvanometer connected up between the gold leaf and the base-plate shows the existence of an electric current in the direction of the light-action through the selenium, as long as the gold leaf is illuminated. I, in the beginning, conjectured that this current was not lasting, but had the character of a polarisation current, which continued only until the molecular modification of the selenium by the light was completed, and a first trial seemed to corroborate this idea. But further experiments convinced me that this supposition was erroneous. In reality, we have here an entirely new physical phenomenon to deal with, which is scientifically of the most far-reaching importance ("*die von grösster wissenschaftlicher Tragweite ist!*")

My experiments have shown that, by the illumination of the gold leaf, a difference of potential is established between it and the base-plate, which is, to all appearance, proportional to the intensity of the light, and which stands forth unchanged so long as the illumination remains constant. Obscure heat radiations do not produce electro-motive force, and therefore the supposition of a thermo-electric action, as the explanation of the phenomenon, is excluded. Mr. Fritts holds that the light waves penetrating into the selenium are transformed directly into electrical current, and therefrom states the fact that the strength of the current is proportional to the strength of the light. They showed themselves to be approximately so, by the collated experiments in the following table:—

| | | | | |
|---|---|---|---|---|
| Strength of the light in standard candles, | 6·4 | 9·9 | 12·8 | 16·8 |
| Strength of the current ............ | 18· | 30· | 40· | 48· |
| Quotient ............ | 2·8 | 3· | 3·1 | 2·8 |

The strength of the light was measured with a Bunsen's photometer, that of the current by the deflections of a sensitive mirror-galvanometer.

With the gold leaf exposed to the light from the south-eastern portion of a cloudless sky, while the sun itself was hidden by neighbouring high buildings, the series of measurements in the following table were obtained:—

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Hour of exposure— | 9.37 | 10.5 | 10.30 | 11 | 11.35 | 12 | 12·30 | 1 |
| Deflection of the galvanometer— | 190 | 196 | 209 | 223 | 250 | 250 | 244 | 235 |

| | | | | | | |
|---|---|---|---|---|---|---|
| Hour of exposure— | 1.30 | 2 | 2.30 | 3 | 3.30 | 4 |
| Deflection of the galvanometer— | 249 | 228 | 188 | 173 | 172 | 108 |

It is shown from the foregoing that the electromotive force of the selenium plate very uniformly increased from 9.30 a.m. until 11.35 a.m., then the current remained nearly constant during two hours, and thereafter again quite uniformly decreased until 3 p.m. With regard to the reason why some of his selenium plates become more conductive during illumination, while others generate electro-motive force, Mr. Fritts give no explanation. He speaks of the uncertainty in the preparation of the plates, of whose properties nothing can be foreseen, and gives various manipulations through which unserviceable plates may often be made useful. There is also still needed thorough investigation, in order to determine upon what the electro-motive light-action of many selenium plates depends. Nevertheless, the existence already of even a single selenium plate having the property described is a fact of the greatest scientific significance, since there is here presented to us, for the first time, the direct conversion of the energy of light into electrical energy.

Note by Mr. Fritts:—The uncertainties mentioned by Dr. Siemens, as existing at the time I wrote the communication referred to (in February, 1884), have since been largely overcome. I have discovered the conditions upon which the electromotive light-action depends, and, with more perfect means for constructing the plates, I believe that I can even now accomplish the conversion of the greater portion of the energy of light into electrical energy. If my theory of the action proves to be complete, when fully carried out and tested in all of its variations, we may ere long see the photo-electric plate competing, in high efficiency of conversion, with the dynamo electric machine itself. I have also ascertained the causes of the frequent alterations in the electrical conductivity of selenium plates, and the conditions which will prevent them. I am now able to foresee the general properties of the plates, and indeed to give them such of the properties as I wish. I can cause a plate to show either an electromotive action or a higher conductivity, when exposed to light, or to show both properties. I can cause one surface of a plate to offer a higher resistance to a current than the other does, and can determine beforehand in which direction this action shall be exhibited. I can cause the resistance of a plate to increase and decrease in the same direction as the strength of the current is changed, or inversely; and can change the character of a plate by reversing its action in these respects, and re-reversing it at pleasure. I have ascertained the *rationale* of the speaking and singing plates described in my paper read before the American Association for the Advancement of Science in September last. Some of the foregoing was known long before the date of my communication to Dr. Siemens; but it is all mentioned here in order to show that the principal points are already pretty well worked out and understood. For obvious reasons I do not yet publish my methods; but many points in the action of selenium do remain which cannot yet be explained or accounted for.

In explanation of the slight irregularity in the action of the electro-motive plate mentioned, it should be stated that it had not been prepared for that purpose, but was sent to him as exhibiting another and entirely different property. During the development of that property, it had received some of the manipulations adapted for giving the electro-motive action, and in consequence thereof it could generate a slight current on exposure to light, although not with the uniformity of a specially prepared electro-motive plate. It should also be noted that the "south-eastern portion of a sky without clouds" (direct sunlight being cut off and excluded) is not a very intense source of illumination. But that fact will only render more satisfactory the proof of the reality of the phenomenon and its nature.

At the time of sending him the samples of my constructions, I had not a very large number of the electro-motive plates, and those were in almost daily use in experiments from which I hoped to deduce the philosophy of the action, so that they could not be spared, and I contented myself with pointing out that this plate could generate a current sufficient, at least, to demonstrate its possession of that property. After having my papers, data, and plates under consideration for nearly a year, Dr. Siemens, than whom there is no higher or better authority, has finally accorded the honour of first discovery to me. Whatever doubts or uncertainties may exist regarding the nature or cause of the phenomena adduced by other investigators, there can be none in this case, since all chemical polarisation and thermo-electric actions are here excluded from consideration, and the phenomenon is here unquestionably the direct conversion of the energy of light into electrical energy.

## BILGRAM'S GEAR CUTTER.

THE gear cutting machine devised by Mr. Hugo Bilgram, which is illustrated in the annexed engraving, is, in some respects, a novel departure from practice, and a radical change in the method of applying principles. The difficulty in cutting the teeth of bevel gear, for which this machine is specially designed, lies in the fact that the curvature of the sections from end to end is not uniform, and tools cannot produce altogether accurate results at once. Messrs. Brehmer Bros., of Philadelphia, send us some particulars of the machine invented by a member of their firm, together with the following remarks by an American contemporary. It should be mentioned that Brehmer Bros. have several of these machines at work cutting gears. The principle of the machine can, perhaps, be best explained as follows:—It is possible to make with any system of interchangeable gears a rack which will correctly gear with any wheel of the set. Any wheel that gears correctly with this rack must, therefore, also gear correctly with any other wheel of the set; and from this it follows that if any number of wheels are made to gear correctly with this rack, they must also gear correctly with one another. If the wheels were to be made with soft material, say wax, the teeth could be formed by simply rolling the blank into the rack, care being taken that the pitch line of the blank will roll on that of the rack without slip. The desirable clearance can be obtained by giving this rack just the converse of clearance. Gears are, however, made of material that cannot be removed by pressure, and the process must, therefore, be modified. The teeth of the rack might be made of hardened steel, with sharp edges at the ends; and by giving them a lateral motion the material could be cut away instead of being pressed to one side. The diagram, Fig. 1, shows distinctly how the tooth of an involute rack would cut its way through the rolling blank, thus forming one of the spaces between two teeth.

This is, in fact, the process by which this gear-cutter accomplishes its work. The cutting tool represents one tooth of a rack, pertaining to an interchangeable set of gears, and it obtains a reciprocating motion in the manner of a shaper tool, while the blank receives a movement as though it were rolling on its pitch surface. In bevel gears the tool representing the rack tooth, while cutting, passes through the varying depths or pitches; therefore the straight line, or involute rack tooth, is the only available one for this purpose. The tool, instead of running parallel with the pitch line, must run parallel with the bottom of the space. This will be more readily understood if it is considered that the rack of a bevel gear is nothing else but a bevel gear forming a pitch angle of 80° at the apex, or a flat, circular disc with teeth converging from the circumference towards the centre. The tool, in cutting, would follow the outline of the teeth of this imaginary plane wheel; and it is evident, therefore, that only one side of the converging space can be formed correctly at a time.

The machine, then, consists of two principal parts—the shaper, which holds and operates the tool, and what may be called the evolver, which holds and moves the blank. In order that the blank shall imitate the movement of a rolling cone, the axis must, in the first place, be moved in the manner of a conical pendulum. To accomplish this, the bearing of the arbor which carries the blank is secured in an inclined position between two uprights to a semicircular horizontal plate, which can be oscillated on a vertical axis passing through the apex of the blank. To complete the rolling action, the arbor must, in the second place, receive simultaneously the proper rotation, and this effect is produced in the machine by having a portion of a cone (corresponding with the pitch cone of the blank) attached to the arbor, and held by two flexible steel bands stretched in opposite directions, thus preventing this cone from making any but a rolling motion when the arbor receives the before-described conical swinging motion. One end of each of the two bands, of course, is attached to the cone, while the other is attached to the framework of the evolver.

Mathematically speaking, a cone does not terminate at the apex, but is extended beyond, and thus consists of two opposite sides of surfaces meeting in the apex. Basing on this principle, the rolling cone above described is placed on the side of the apex, opposite that on which the blank is placed, in order to avoid an interference with the tool.

The feed mechanism effects a slow intermittent movement of the semi-circular plate which supports the inclined arbor, thereby producing a slowly progressing rolling of the blank while the reciprocating tool forces its way through the metal. The feed can be reversed by the turning of a knob, or disengaged altogether, permitting the blank to be rolled to the one or the other side by a hand-crank.

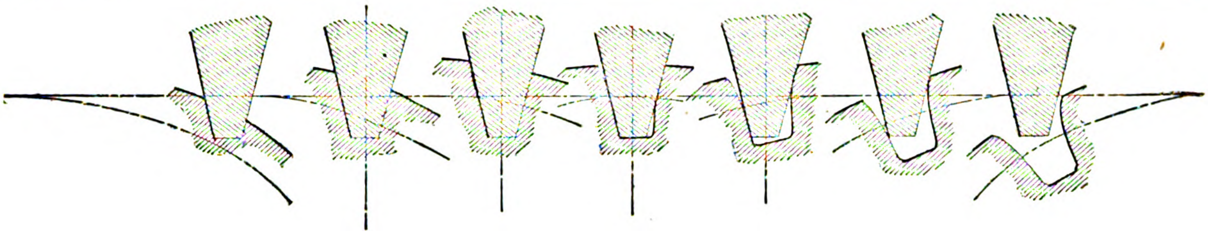
The arbor carrying the blank can be rotated independent of the rolling cone by means of a worm wheel, worm and index plate, which enables the blank to be presented to the cutting device at properly spaced divisions corresponding with the number of teeth of the desired wheel.

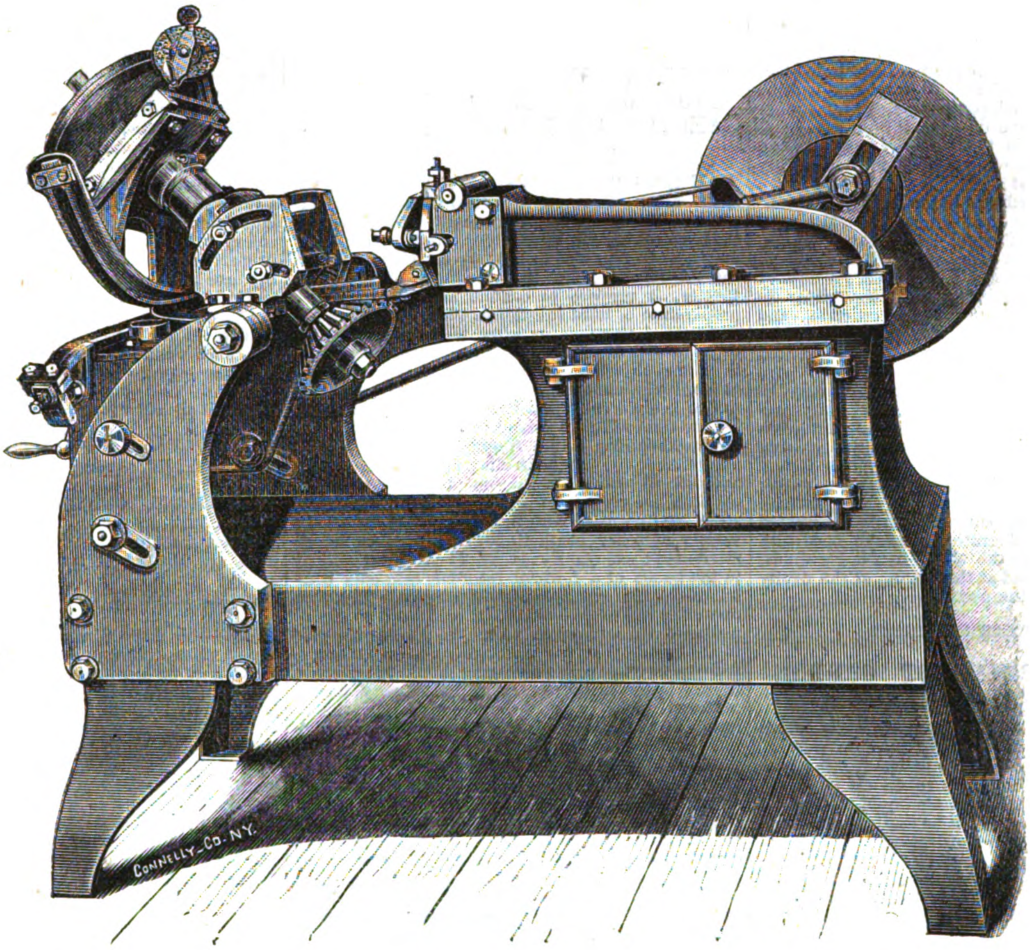
It is essential that the tool should be so adjusted that the lowest point of the cutting side should move exactly towards the apex of the blank, and, in order to set the tool, a gauge is provided by which the tool can be adjusted. A distance block is used between this gauge and the tool; this mode admits of a high degree of accuracy, since variations of distances can readily be detected by the touch when the eye ceases to discern.

When a wheel is to be cut out of the solid, the tool is at first adjusted at a slight distance from its correct position, and after each cut the feed motion of the evolver causes the blank to slowly roll, and allows the tool to cut out the stock in the manner shown in the diagram. All spaces are now treated in the same manner by using the index device, whereupon the tool is properly adjusted for one and then for the other side, each adjustment being followed by a repetition of the process in order to finish both sides of the teeth.

In securing the blank to the arbor, great care must be exercised in placing its apex exactly in the centre of the evolver. A special device enables the operator to gauge the distance of the ends of the teeth from the centre of the evolver, and, whenever this distance agrees with that calculated from the drawing, the apex of the blank is in its right place.

The inclination of the arbor which holds the blank is made adjustable, so as to adapt it to the angle of the desired gear. This adjustment must be exactly concentric with the centre of the evolver, *i.e.*, the apex of the blank. The rolling cone is





CONNELLY-CO. NY.

made detachable, in order that it may be replaced by such cones as correspond with the angle of the blank to be cut; but as the number of cones required would be unlimited, means have been devised to make a limited number of cones suffice.

The tool consists of a triangular bar of hardened steel, forming at the point an angle of 30°, 15° on each side, and held by a special holder. By grinding, it can be more or less truncated to suit the pitch of the gear to be cut. By this form of tool a much higher degree of accuracy is attainable than with tools having curved faces made to a gauge. The proper up and down and sideway adjustment is effected by two slides working at right angles, and operated by screws. The clamp which fastens the tool-holder is so constructed that it also clamps these said slides to the apron, securing the necessary stability. The apron is fitted with great care; the box in which the apron works is made in parts, and the faces are turned true with the pinholes, in order to get these faces exactly at right angles with the pin. The latter is fast in the apron, and revolves in the two sides, in which it has taper fits that the wear may be taken up. A device for lifting the apron during the return stroke prevents the dragging of the tool. The oscillating movement of the connecting-rod is employed for this purpose, by having a bar hinged at one end to a clamp which can be shifted on the connecting-rod while the other end impinges on the apron. By a lifting of the crank end of the connecting-rod, the loose end of this bar is pushed forward and the apron is lifted. It is easy to so adjust the clamp that this lifting action will occupy the time of the return stroke. The tool-bar is moved by a Whitworth quick-return motion, which is attached directly to the belt pulley. A double counter-shaft connected by cone pulleys is employed to change the speed if a shorter or longer stroke is desired. Gears cut on this machine are practically as nearly perfect as it is possible to produce plane surfaces on a planer. For this reason a careful preparation of the blanks is essential. One feature of involute gearing, which in practice in often troublesome, can be fully met by gears cut by this machine in a manner to be described. Whenever a pinion with a comparatively small number of teeth gears with a large wheel, there is a tendency of the points of the teeth of the wheel to cut into the flanks of the pinion. Reuleaux recommends that the number of teeth of the smallest gear of a set of interchangeable wheels should not be lower than 30. In practice this defect is, however, hardly noticeable when the number of teeth is not less than 20, but for a smaller number it becomes perceptible. In spur gearing the difficulty is generally met by giving the teeth of pinions more than the theoretical rounding; but this expedient is not a perfect cure, as may readily be attested by the experience of those who have cut 12-tooth involute pinions. Bevel wheels being always made in pairs, the above difficulty can be overcome by making the tooth-face of the wheel shorter than usual, *i.e.*, by cutting it off at that point of the face-involute, which, in running, will come in contact with the root of the involute of the pinion. By the extent to which the face of the wheel teeth is shortened by this measure, that of the pinion teeth is increased, and the flanks are made to correspond. It is evident that where this correction has been applied, the pitch line of the pinion is nearer to the base of the teeth, and that of the wheel nearer to the top than in the ordinary practice.

## RECOVERING SILVER FROM FIXING BATHS.*

FEW photographers who are not chemists are aware of the small percentage of the total silver in a sensitive gelatine plate which goes to the formation of the image. This is the case, notwithstanding the fact that, unlike wet collodion, the negative image is formed at the expense of the silver bromide which is itself reduced. Now as the function of the fixing bath is to remove all the unreduced bromide and leave remaining in the film only the portion that has been reduced by the developer to the form of metallic silver, it follows that a fixing bath which has exercised its functions upon several plates soon becomes surcharged with silver. It is one of the easiest operations in the whole realm of chemistry to make this saturated fixing bath yield up every particle of silver therein contained; and this being so, it is a pity that amateur photographers should heedlessly throw away so valuable a solution as a used-up fixing bath. We say "amateurs," advisedly, for professional photographers are too much alive to their own interests to permit any such waste. Each of them has his barrels, into which every drop of old hyposulphite solution, whether that from negatives or prints, is thrown, in order to have the silver extracted.

The following is the course we advise for the adoption of the user of dry plates on a moderate scale, who is not averse to the reduction of his expenses by saving his silver waste: Obtain a two-gallon glass jar having a loosely-fitting cover, and about 4in. from the bottom drill a hole in the side This hole is then fitted with a wooden plug, or, what is better, a small tap, which is retained in place by screwed nut, aided by rubber washers. This jar is placed on a shelf in a garden or outside of a window; at any rate, in some place with which there is direct open-air communication. This is rendered necessary on account of the offensive smell emitted at a subsequent stage. Into this the waste-fixing solutions are poured, and when the jar is nearly full, a small portion of a solution of potassium sulphide (sulphuret of potash or liver of sulphur) is poured in and mixed with the solution by stirring with a wooden or glass slab. Instantly there is a dense deposition of sulphide of silver in the form of a dark mass. Precisely how much of the sulphuret ought to be added can be determined only by experiment. After the precipitate descends a little, if the addition of two or three drops of the sulphuret is not seen to produce a further precipitate, then has enough been added; but if this addition causes further blackness, it must be continued until all the silver is found to be converted into sulphide. It is advisable that no more be added than suffices to effect this end. Owing to the slowness with which the precipitation takes place, it may, in many cases, be expedient to have in use two such jars as that described. After the precipitate had settled down to below the level of the hole or tap in the side of the jar, the supernatant liquid must be run off through this aperture. Upon replacing the plug, water may be added to wash the sulphide of silver which is insoluble in water. In this case the deposition will take place more quickly than before. Having obtained the silver sulphide as a dark pasty mass, the next query arises: What shall we do with it? In reply: It can either be placed in the hands of a professional metallurgist or reducer, who will most willingly either purchase it at full value or fuse it into a button of metallic silver; or, secondly, it can be converted into nitrate of silver by the addition of nitric acid into which it readily dissolves; or thirdly, it may be mixed with a flux composed of carbonate of soda, 7oz.; carbonate of potash, 7oz.; nitrate of potash, 2oz. Mixing this with the silver in equal proportions, placing in a crucible, and then fusing in a furnace, this gives a button of pure silver. The nitrate of silver obtained by the second operation is not sufficiently pure for some purposes, but, of course, it may be easily purified. The following is a pretty experiment, and one which is also useful, inasmuch as it reduces the sulphide very quickly. Having cut a hollow into a block of wood, place it in a mixture composed as follows:—Sulphur, two parts; nitre, four parts; fine sawdust, two parts; with an equal volume of silver sulphide. Apply a lighted match to this, and deflagration will take place with great rapidity, and at the close, in a few seconds, the silver will be found at the bottom of the cavity as a beautiful white lump of shining metal.

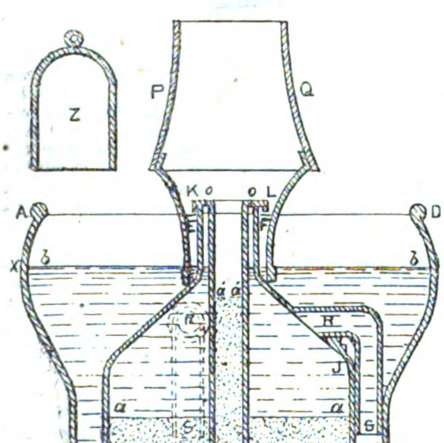
## THE BISULPHIDE OF CARBON DISINFECTING LAMP.

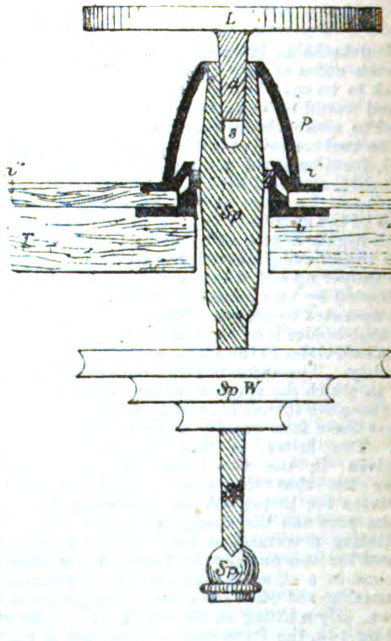
THE experiments made in Paris with bisulphide of carbon for disinfecting purposes were so satisfactory that a device was called for in which the liquid could be safely burned. It is an extremely volatile and inflammable liquid, and under ordinary conditions could not be ignited in a closed room without great danger of setting it on fire; but by means of a peculiar lamp devised by M. Ckiandi-Bey, any quantity of the bisulphide can be burnt with perfect safety. The lamp is made of copper, and consists of an exterior receptacle, A B C D, in which is placed the lamp I H E F. Three bent copper tubes, R S, pass through the sides of the lamp. The cylindrical tube, K L M N, containing a cotton wick in the upper part, reaches from the mouth of the lamp nearly to the bottom. The flame is surrounded by a copper chimney, P Q. The method of operating is as follows:—The lamp is filled with bisulphide of carbon to about the level *a a*. The outside receptacle is then filled with water to the level *b b*. By means of the bent tubes, R S, the water passes into the interior of the lamp, and forces the bisulphide up to the level *a′ a′* in the copper tube, where it is absorbed by the wick, and can be ignited at the top of the tube *o o*. As the bisulphide burns away, it is replaced by the water; and the lamp finally extinguishes itself. The combustion can be regulated by adding more or less water, so as to raise or lower the level *b b*. There is no danger of explosion; as the bisulphide is entirely surrounded by water, which keeps it cool, and only a small portion at a time is brought in contact with the flame. In disinfecting a room, about one pound of bisulphide is allowed to every thousand cubic feet. Any coloured materials likely to be bleached by the gas should be removed, the bisulphide ignited, and the room tightly closed, and left for several hours. After disinfection, the room should be thoroughly aired; and care must be taken not to inhale the gas.



## OBSERVATIONS ON THE PREPARATION OF MINERAL AND ROCK SECTIONS FOR THE MICROSCOPE.*

By John Ernest Ady.

DURING the past few years the study of the minute structure of minerals and rocks has received the attention of so many able geologists that microscopical mineralogy and petrography may now be regarded as a fairly established means for the identification and diagnosis of inorganic species. I propose to confine my remarks to the preparation of hard substances which do not require any special previous or after treatment to enable them to withstand the mechanical methods to which they are subjected. There are many trifling details of manipulation, the neglect or observance of which suffice to draw the line between failure and success. By the term failure I intend to imply that slovenly habit of securing a thin fragment of a section and mounting it anyhow, with clinging particles of dust and dirt, to which such errors of observation as a detailed description of rough surfaces, rugosities, striæ, cavities filled with unknown products, and a variety of other conflicting evidences, are to be attributed; whereas a successfully-prepared section, in the hands of a faithful recorder, can only contribute to the advancement of science. The first operation in the preparation of sections is to secure a slice of the mineral or rock. In the former case it is obvious that for purposes of investigation a definite series of sectional planes should be selected; in the latter instance, especially in very finely-textured rocks, without any natural or superinduced peculiarities, such as occur in finely-laminated examples, slates, schists, &c., or the presence of specially developed and local particles, the plane of section is immaterial, and a chip taken with a hammer may often suffice. The reduction of the slice may be accomplished by hand, or with the aid of a grinding bench. In either case the processes are essentially the same; the result to be aimed at is a section of the desired thickness, which shall be perfectly even and free from superficial scratches. The tenuity of the preparation must of course be regulated by the special requirements of each case; as a rule, however, the thinner a slice can be made the more valuable it becomes to the general investigator, especially with high powers of the microscope; minute endomorphs, cavities, and traces of fluidal structure may thus be revealed, and inferences often of great importance deduced therefrom. The mode of preparing hard sections is briefly as follows:—The slice or chip must be ground absolutely level and perfectly smooth on one side; it is not necessary to polish the face. The smooth facette may thereafter be firmly cemented on to a suitable piece of glass, and the other side then reduced until a sufficiently thin section is obtained. To do this by hand, a few soft metal plates, preferably of pewter, zinc, copper, or lap-metal, each about 12in. square, and ¼in. thick, three sizes of emery powder, and one or two Water-of-Ayr hones, are in reality all that is necessary. Glass plates are not to be tolerated, since they rapidly wear away irregularly unless extreme care is taken. For the final operation of grinding, flour emery which has been used and washed, or mirror-polishers' powder, is to be preferred. To produce a perfectly flat face upon the slice the surface of the plates should be slightly raised at their centres, so as to be somewhat convex. This may be produced by heating the central part over a spirit or Bunsen flame, when the four corners of the square will tend to bend slightly downwards, and give the desired degree of convexity to the upper grinding surface. The plate may then be fixed upon a support of wood covered with a layer of plaster of Paris, so as to prevent a springing motion during the process of grinding. The use of flour emery will secure a tolerably smooth surface, free from any serious scratches or roughness; but it is advisable to make use of a Water-of-Ayr hone, with a plentiful supply of water, in addition, to insure success. Indeed, *two* hones may be advantageously employed, and their surfaces are to be specially prepared beforehand thus:—The first hone, about 6in. long and 1½in. in breadth, is to be rubbed rapidly from end to end, longitudinally in one direction, upon a level slab of fine sandstone. This will develop a slightly convex surface upon the hone. The second hone, of similar proportions, must be treated in the same way, but it should in addition be further rubbed upon a slab of fine marble, so as to secure a smoother surface also slightly convex. The value of a convex grinding or polishing surface where the pressure is applied by the hand has long been known to practical mechanicians, for it is upon this principle that the so-called engineer's file is constructed. To the neglect of this item may be traced the cause of those inequalities which result in a section thick towards the centre and thin at the edges. In fastening the smoothened surface of the slice to a piece of glass, the best cement substance I have found for the purpose is that made of an admixture of Venice turpentine and orange shellac. The turpentine should be heated in a sand or water bath, and enough shellac ought to be added to it to produce on cooling a thoroughly hard yet tough solid; it may be tested from time to time by the removal of a small portion. The advantages of this cement are manifold: it is not prone to imbed particles of emery during the processes of grinding, its adhesive properties are exactly suited to the requirements of the case, and it is perfectly soluble in ordinary methylated spirit. By surrounding the edges of the slice with a small quantity of the cement, the borders of the latter will be perfectly protected. The slice ought to be fixed on to the small preliminary square of glass, with the fastening substance melted upon it over a spirit or Bunsen flame; it should be firmly pressed upon the glass slip (which, by the way, is all the better for being made of the best flattened plate-glass, about ¼in. thick, and 1½in. square) to the entire exclusion of air-bubbles. The process of reduction may be carried on with Nos. 60 and 80-hole emery powder, until in dark specimens, *e g.* basalts, &c., the slice becomes translucent. Flour emery may then be used, and the final touches given upon the Water-of-Ayr hones. During the latter stages, the specimen ought to be repeatedly examined under the microscope. All that is necessary now is to remove the finished section from the preliminary slip of glass. This may be best accomplished by soaking it in a saucer full of methylated spirit. The slice ought to float off of itself in the course of a few hours; it must not, on any account, be forced off. After detachment, it should be transferred to a dish of clean spirit for an hour or so, and gently washed therein with a fine camel's-hair or sable pencil. From the clean spirit the slice should be removed by means of a special lifter (a fine brush or stout needle will do), and placed between slips of clean white tissue paper, where it will dry rapidly and be ready for mounting. The best mounting fluid for rock sections is a filtered solution of equal parts of Canada balsam and gum damar in pure benzol. Hardened Canada balsam dissolved in benzol and filtered may also be used. A drop of the solution ought to be placed upon a clean warmed slip of glass, the section placed thereon, covered with another drop, and laid aside for about 10 or 12 hours in a dust-proof box, or under a bell glass. This process permits the medium to assume a suitable consistency before the cover glass is applied to the preparation. After exposure a fresh drop of balsam may be placed upon the



---

section, and a gently warmed cover glass lowered upon the whole. The labour of grinding sections of minerals and rocks for the microscope by hand is so tedious that few persons would follow that process where they could resort to a suitable grinding bench. Many instruments have been devised for this purpose, the best one in the English market being that of Messrs. Cotton and Johnson, and called the "Amateurs' Lapidary Machine." There is room, however, for vast improvements in instruments of this kind; those that are now made for scientific inquirers are either too expensive or mere toys; whilst working lapidaries use benches which require almost a term of apprenticeship to enable one to manage them. What is wanted by the petrologist is a thoroughly good machine with a horizontally disposed fly-wheel, treadle action, firm steady bearings, and the entire system so arranged as to admit of the ready change of laps, and the cleanly application of emery with the greatest possible utility. I am glad to be able here to describe a machine which fully meets all the wants I have just enumerated, and which has hitherto remained unnoticed. With its aid several hundreds of sections of the most perfect description were prepared in illustration of my journal on microscopical petography. The vertical treadle motion is modified into a powerful horizontal one by means of a strong cord passed over a pulley and attached to the crank of a fly-wheel. A connecting strap transfers the motion of the fly-wheel to a small horizontally-placed spindle-bearing wheel. The lower end of the spindle works upon a fixed iron bearing, whilst its upper extremity is free and slotted to receive the central attachment pins of the grinding discs. The circular grinding discs are provided with cylindrical rod-like attachment pins screwed into the centres of their lower faces at right angles thereto; they are simply allowed to slide into the receiving slot of the spindle-head, and can therefore be readily changed; their weight, and the pressure applied to their upper surfaces during the process of grinding, are sufficient to maintain them firmly. The fly-wheel works between two metal bearings supported by a strong framework, which can be made to slide forwards or backwards in the body of the bench by working a large adjustable wooden screw; thus, when the connecting strap becomes somewhat slack it can be speedily tightened by merely turning the screw-head. Before placing the lap into the slot of the spindle-head, the waste emery box must be placed around the latter, and over this a protecting metal cup-shaped cap is slid to prevent the possible passage of dirt to the working parts of the instrument. Lastly, the subjoined figures with explanatory notes and measurements will show the details of this new lapidary's lathe far better than any verbal description alone. It may be taken as a working plan.

### Explanation of Engravings.

Diagrammatic sectional drawing of lapidary's lathe for petographical work.—T, top of table; *u u*, upright supporting legs; J, middle joist; *tr*, treadle, *cd*, cord of treadle passing over pulley wheel (*p w*) to crank (*cr*) of fly-wheel (*f w*); *st*, strap from fly-wheel to spindle-bearing wheel (*sp w*); *Sp*, upper end of spindle; *Sp* 1, lower part of spindle resting on bearing (*Sp B*); *u b*, and *l b*, upper and lower bearings of fly-wheel, sunk in sliding frame (*fr*), which can be regulated by wooden screw (*w s*). The lower bearing, along with the inferior arm of the sliding frame, move in a limited groove in the joist (J), which is specially morticed at this part.

Enlarged diagram of grinding apparatus. — *i*., circular brass ring bordering aperture for upper end of spindle (*Sp*); it is provided with an upward projecting rim. The brass cap (*c*) acts as a steadying bearing to the spindle head (*Sp*); *i'*, circular metal ring with upward projecting rim fastened on edge of central aperture of waste emery box (*b*); the brass protecting cap (*p*) comes over the edge of this rim, and is apposed above to the free extremity of the spindle head, thus effectually preventing the entry of dirt to the bearing (*c*); *i''*, iron pegs for securing box (*b*) in its place. L, lap, or grinding disc; *a*, attachment pin of lap, is somewhat conical, and does not quite fill the slot (*s*); thus providing a grip which tends to become more firmly fixed during the process of grinding.

### Working Measurements.

Table: Height, 38in.; length, 40in.; width, 20in.

| | in. |
|---|---|

| Length of arms of sliding frame (*fr*) ........ | 10 |
| Side of square waste emery box (*b*) .......... | 12½ |

**The Chloris Baudet Cell.**—A Chloris Baudet "unpolarizable" battery was tested at the Philadelphia Exhibition. The cell is described as follows:—An outer rectangular cell, 22cm. by 18 by 9, and a porous cell for the zinc plate. Two porous jars, one for crystals of bichromate of potash, the other for sulphuric acid; one with holes and the other without; two plates of carbon, each with suitable wire connections, and a suitable cover for the whole. The solutions used were a saturated solution of bichromate of potash for the outer jar holding the carbon, and a super-saturated solution of acid sulphate of potash for the porous jar containing the zinc. In the test cell the bisulphate of potash was used in the porous jar. When first set up this cell had an electromotive force of 1·87 volt. It was then put in circuit with a resistance of 5·8 ohms, including a galvanometer, when the deflection was 47°, with a current of ·226 ampère. The internal resistance of the cell was 1·3 ohm, and the zinc was a half-inch rod immersed to a depth of about three inches. The needle fell one degree in the first five minutes, when after an hour it rose to 47½°, standing steadily for five hours; the next morning it was 45°. Here it remained practically constant for about 28 hours, when it suddenly fell.

THE East Coast railway from Newcastle to Edinburgh has had to be diverted about 2½ miles to the north of Berwick, owing to the encroachments of the sea, and at a cost, exclusive of purchase of land, of nearly £14,000.

# SCIENTIFIC SOCIETIES.

## ROYAL ASTRONOMICAL SOCIETY.

THE June meeting of the society was held at Burlington House, on Friday, the 12th inst., Ed. Dunkin, Esq., President, in the chair. The Rev. Thomas Perkins, M.A., of Shaftesbury School, Shaftesbury, Dorset, was elected a Fellow of the society.

Col. Tupman reported that sixty-two presents had been received by the society since their last meeting. Amongst them was a photograph of a portion of the Milky Way, taken by the Brothers Henry, of the Paris Observatory, with a new object-glass of their own construction of 13in. aperture and 11½ft. focal length. With an exposure of 60 minutes stars of the 14th magnitude were shown.

Mr. Knobel read a paper by Mr. W. F. Denning, on "The Velocity of Meteors." At the last meeting it was stated that in order to account for the stationary meteor radiants, which Mr. Denning claims to have discovered, it is necessary to assume that the meteoric bodies belonging to them come from outer space with a velocity at least fifty times as great as the velocity of the earth in its orbit about the sun. Mr. Denning wished to state that no such velocities had been observed by him. He agreed with Col. Tupman as to the difficulty of accounting for these long-enduring showers, but it was certain that the meteors coming from the fixed radiants did not meet the earth with velocities fifty times as great as the meteors belonging to known planetary showers. The question had been asked whether the velocity of any meteors belonging to fixed radiants had been determined by simultaneous observations of observers stationed at a distance from one another. Mr. Denning stated that there were several instances in which such observations had been made, and that the velocities did not differ greatly from the velocities of meteors belonging to the planetary streams.

Mr. Ranyard said: This seems to be a very important series of facts which Mr. Denning has communicated. If the velocity of a meteor shower coming from outer space were at all comparable with the velocity of the earth in its orbit, the radiant would, in the course of the year move in a circle many degrees in diameter, because the direction in which meteors appear to approach the earth is not the direction in which they are really moving in space; but it is determined by the relative motion, which is compounded of the meteor's motion and the earth's motion in its orbit. Meteors moving with a velocity fifty times as great as the ordinary planetary meteors, would probably give rise to quite a distinct class of phenomena. The heat generated is proportional to the square of the velocity, and consequently at the same altitude such rapid-moving meteors would be consumed in an incredibly short space of time. Planetary meteors become incandescent at a height of seventy or eighty miles above the earth's surface, and meteors moving with a velocity fifty times as great it is possible to conceive might become incandescent at twenty or even fifty times as high in a region where the atmosphere is very much rarer; but with such enormous velocities it seems probable that the process of burning the meteor would be much more rapid, and that the air would behave almost like a solid, and the meteor would be broken up with a rapidity comparable to the duration of an electric flash.

Col. Tupman endeavoured to show, by means of a diagram on the black-board, the relative heights above the earth's surface at which it would be necessary to suppose that meteors became incandescent, in order that the angular velocity of the two classes of meteors should correspond. The small relative velocity, compared with the earth, is, however, proved by the fact that the apparent velocity of the meteors, from both classes of radiants, is dependent upon the position of the radiant with respect to the apex of the earth's way. When the earth meets the meteors, their apparent velocity is much greater than when the meteors catch up the earth from behind.

Mr. Bryant read a paper on "The Elliptic Elements of Comet (Ross) II., 1883." The orbits of which elements have already been published of this comet, do not present such an agreement as might have been expected on the assumption that the comet is moving approximately in a parabola. By the advice of Mr. Hind, he had rejected all observations except those of Mr. Tebbutt; but he still failed to find a parabolic orbit which would correspond to them. Mr. Bryant, therefore, undertook to investigate its elliptic elements, and arrived at two sets of elements, both of which satisfied Mr. Tebbutt's observations with an error of six hundredths of a second of arc of Right Ascension. One gives a period of 87 years, and the other a period of 94 years.

Mr. Knobel read a paper on Al-Sufi's star magnitudes. He compared the discrepancies in different manuscripts, and illustrated on the blackboard how some of them may have been supposed to have arisen. In Ptolemy's catalogue a star of the 3-4 magnitude is indicated by the Greek letter γ, followed by the word ελασσων; a star a little larger than the third magnitude would be γ, μειζον, the letter γ signifying 3. The Arabic copyists not understanding the meaning of the words μειζον or ελασσων, as greater or less, translated them in various manners, sometimes giving the Arabic initial letters of the words and sometimes contractions.

A paper by Prof. Pritchard was read, intitled "An Inquiry as to the Grounds for Criticism by the Astronomers of Harvard College on the Oxford Stellar Photometry." Prof. Pickering had stated that the results obtained with a Wedge photometer should theoretically be affected by the brightness of the background of sky. In order to test this assertion Prof. Pritchard had examined about 1,000 observations of Polaris which had been made at Oxford during the last three years; he had had the observations divided into four classes corresponding with the four phases of the moon, but the part of the wedge at which the star was extinguished was found to be practically the same, whether the moon was full or new, there being only a difference of about one-hundredth of an inch in the average reading of the wedge for full moon and new moon which would correspond to a difference of about one-fiftieth of a magnitude. The four readings were 4·77, 4·76, 4·74, and 4·75 inches on the scale of the wedge. The paper then proceeded to deal with the probable errors of the measures given in the Harvard Catalogue, and in the Oxford Catalogue Prof. Pritchard claimed that there were no systematic errors in the Oxford Catalogue depending on the brightness of the field of view, or on the brightness of neighbouring stars. The magnitudes of the Harvard Catalogue mostly depended on measures made upon only three different nights, and as these measures are relative measures depending upon the comparison of one star with another, Prof. Pritchard claims that they are not likely to be as accurate as absolute measures made with an instrument which is independent of the sky illumination.

Mr. Stone said that he did not think Prof. Pritchard's way of comparing the various measures of the Harvard Catalogue with his own was fair. He had compared the extremes of the measures made at Harvard with the difference between the means of measures made at Oxford. He was very surprised to hear of the result which Prof. Pritchard had arrived at in comparing the differences between observations made at full moon and new moon. If Prof. Pritchard had determined the magnitudes by a differential method by which one star was compared with another, he could understand that both stars might be similarly affected, so that the relative brightness might not be changed, but with absolute measures, such as Prof. Pritchard endeavoured to make, he could not understand such a result. To the eye, and in the telescope, there were two or three magnitudes of difference between the apparent brightness of stars at new moon and full moon.

The Astronomer Royal said that he had had the advantage of examining Prof. Pritchard's work, and must congratulate him upon the accuracy he had introduced into celestial photometry by his wedge-photometer. He could understand how it was that the absolute measures of the brightness of the Pole-star differed by only about $\frac{3}{50}$th of a magnitude under different conditions. of moonlight illumination. The light of the star disc is enormously brighter than the light of the background, and it stands to reason that long before the star has disappeared, as the wedge is pushed onward, the background will have faded out of view, and will have no effect on the retina. Its effect would only be the same as absolute blackness; this objection, therefore, utterly falls to the ground.

General Tennant said that he had had an opportunity of examining Professor Pritchard's observations with Mr. Common, and he thought that a great part of the accordance which they seemed to show was brought about by the fact that Professor Pritchard rejected observations in a very wholesale way when they were not accordant.

Mr. Knobel said that he had looked very closely into the matter, and had himself made a number of observations of star magnitudes by the method of limiting apertures, and he had found that the result very much depended on the rapidity with which an observation was made; when the aperture was very slowly diminished, the retina retained its sensibility and could follow the star further than when the aperture was rapidly closed. He had especially asked Professor Pritchard how the observations were made, and whether the wedge was rapidly or slowly pushed onwards. Professor Pritchard stated that the star's brightness was greatly diminished, and then the screw of the wedge was rapidly turned. He thought that an explanation of the strange accordance of the observations might possibly be accounted or in this way.

Father Perry said that he agreed with Mr. Knobel; he had found a great deal of difference in the readings when the wedge was moved slowly or rapidly. He thought that the strange accordance might be due to the fact that the observer brought the wedge very nearly up to the old reading, and then moved it through a turn of the micrometer screw, which was not very far. He could, he believed, if he liked, extinguish the star over a large range of the wedge by such a method.

Lord McLaren said that he had endeavoured to make some observations of star magnitudes with a wedge photometer, and had found that there was a great deal of difference in the place where the star disappeared when the wedge was moved slowly or rapidly.

Mr. Ranyard said one would have expected a much greater difference in the measures when they were determined absolutely than when they were determined by Prof. Pickering's method of comparing one star with another, for a difference of clearness in the atmosphere from one night to another would probably make a greater difference in the brightness of a star than would be caused by the difference of clearness in the direction of the two stars which were compared on the same night.

Mr. Green showed some drawings of Jupiter, and called attention to some dark red spots which had recently appeared, following the well-known red spot, and in about the same latitude upon the planet.

The President mentioned that Mr. Todd, the Government Astronomer of South Australia, was present at the meeting, and called upon him to give an account of his work.

Mr. Todd said that he had not expected to have been called upon, and had made no preparation. When he first arrived in the colony the Observatory was very poorly equipped. One of his chief duties was to determine the time for the colony. This had not been very effectively done; a gun was fired every day at one o'clock, and there was a tradition that a chronometer-maker in the town used to set his chronometers by the gun, and the man who fired the gun would for long periods take his time from the chronometer-maker's window. One of their duties had been to determine the boundaries of the colony, which involved laying down a parallel of latitude as well as a parallel of longitude. They had also observed the Transit of Venus in 1874, and had given some attention to the planet Jupiter, and eclipses of its satellites, and had on more than one occasion seen them through the limb of the planet.

The following papers were also laid on the table, and taken as read:—Observations of the Satellites of Saturn, and of the companion of Sirius, made at the United States Naval Observatory, Washington, by Prof. A. Hall; Ephemerides of the Satellites of Saturn 1885–86, and Ephemeris of the Satellite of Neptune 1885–86, by A. Marth, Esq.; On Daylight Occultations of Aldebaran in 1885, by Mr. J. R. Hind.

**New Secondary Battery.**—At a recent meeting of the Berlin Physical Society, Dr. Kalischer described a new secondary battery, intended to overcome the disadvantage of the usual accumulators—namely, that the sheet of lead used as anode was very soon destroyed. This object he is said to have attained by adopting a very concentrated solution of nitrate of lead as electrolyte, and iron as anode. The iron on being immersed in the solution of lead became passive, and resisted every corroding effect of the fluid; in other respects the peroxide of lead on the electric charge became deposited at the anode as a very firm coherent mass, enveloping and protecting the iron on all sides. The charge was continued till the greater part of the nitrate of lead was decomposed, a condition which was marked by the occurrence of a greater development of gas at the anode. At the beginning of charge all development of gas must be avoided, or otherwise the peroxide of lead, or, more correctly, the hydrate of peroxide of lead, became covered with bubbles. As cathode a sheet of lead was used, but it was attended by two disadvantages. In the first place, the lead during the charge, separated itself at the cathode into long crystal threads, which soon passed through the fluid and produced short closing (of the current). In the second place the nitric acid, which remained in the fluid after the separation of the lead, acted very powerfully on the sheet of lead. Both disadvantages Dr. Kalischer avoided by amalgamising the cathode. This accumulator of iron, concentrated solution of nitrate of lead, and amalgamised lead yielded, after the electric charge, which could be carried out without any special preparations, a current of about 2 volts; after about six hours' discharge, however, the electro-motive force sank to 1·7 volt, but, on the battery being left to itself for twenty-four hours, it became a little increased. According to the measurements hitherto taken, the functions of this accumulator were satisfactory. An attempt to substitute sulphuric manganese for nitric lead in this battery did not answer the purpose, as the peroxide of manganese separated itself, not in a continuous layer, but in loose scales.

# SCIENTIFIC NEWS.

THE scientific world learnt on Monday last, with some surprise and with much regret, that Prof. Fleeming Jenkin was dead. His intimate friends knew that his health was in far from a satisfactory state; but few anticipated so untimely a termination to a career which has been of the greatest service to practical science. The deceased professor was born in 1838 at Stowting Court, Kent, and pursued his studies at Edinburgh, Frankfurt-on-the-Main, Paris, and Genoa; and after taking his M.A. degree, he entered himself as an "apprentice" in the locomotive shops at Marseilles, whence he passed to Fairbairn's at Manchester in 1851. It will be seen that Fleeming Jenkin had of necessity acquired a good deal of experience before he was 21, and the very variety of his educational training enabled him to attain a position at an early period in the life of a scientist. In 1857 he had charge of the electrical testing of the first Atlantic cable during the progress of its manufacture; and in 1865 was appointed professor of engineering at University College, London—a post he held until he became the first occupant of the chair of engineering at Edinburgh, a professorship which he held until his death. The loss of such a man in the prime of life, just as his scheme of telpherage or electrical transmission, is about to be put into practical work, is to be regretted, for his many-sided experience would have been of great value in determining several questions which are attracting much attention.

Prof. Robert von Schlagintweit, the eminent ethnographer and geographer, died on Saturday in Giessen at the age of 52. The name of the deceased is chiefly connected with the journey of scientific investigation made by him in 1854-57 in Central India and the Himalayas in conjunction with his brothers Hermann and Adolphus. The expedition was fitted out at the expense of the King of Prussia and the British East India Company, and added many important and interesting facts to our knowledge in the domains of geography, meteorology, geology, and ethnology. An account of the journey was published in English under the title of "Results of a Scientific Mission to India and High Asia." Prof. Robert von Schlagintweit also travelled in North America, and wrote several shorter works on his experiences there. For several years previous to his death he had filled the post of Professor of Geography at Giessen.

The Rev. R. Harley, F.R.S., is retiring from the principalship of Huddersfield College, after a long and distinguished career as a teacher of mathematics.

It is stated that for the professorship of chemistry at South Kensington, vacant by the resignation of Dr. Frankland, there are a large number of candidates, amongst them, Prof. Ayrton, of the Technical Institute; Prof. Dewar, of Cambridge; Prof. Hartley, of Dublin; Prof. Odling, of Oxford, and Prof. Thorpe, of Leeds. The emolument or salary, according to Whitaker, exceeds £1,600.

The conversazione of the Royal Society was held last week at Burlington House, when many objects, scientific and mechanical, were displayed in the several rooms, and were inspected with evident interest by the guests as they passed from room to room. Among the mechanical contrivances which appeared to excite the chief interest was Tate's calculating machine, exhibited by the inventor, by means of which eight figures can be multiplied by eight figures in the space of about 15 seconds. There were also many entomological and botanical specimens under microscopes exhibited, as well as samples of Edison incandescent lamps exhibiting molecular shadows and transparent deposit of copper.

It may interest a few to learn that the Council list of proposed Fellows was duly elected. The following are the names; Major Baird, R.E.; P. H. Carpenter, D.Sc.; Sir A. Clark, M.D.; A. A. Common, F.R.A.S.; Staff-commander E. W. Creak, Prof. E. Divers, Dr. H. Hicks, W. M. Hicks, M.A.; F. R. Japp, Ph.D.; Dr. A. M. Marshall, Prof. H. N. Martin, D.Sc.; C. O'Sullivan, Prof. J. Perry, Prof. Sydney Ringer, and S. H. Vines, D.Sc.

At Christiania, Herr A. Olsen, an optician, has erected a large refractor in the Great Park, and the public can make observations of the celestial bodies on payment of a small fee. An attendant gives explanations. Herr Olsen's object is to foster a love of observational astronomy.

A good instance of what can be done when there is the will, is supplied by Mr. Roberts in his late report on the Cambridge Local Lectures. He tells a story of two miners at Backworth, Northumberland, who, after their day's work, walked about five miles in order to attend a course of lectures on chemistry given at Cramlington. That meant a walk of ten miles in order to gain a little knowledge. But these miners went further still; they took copious notes, and formed a class at Backworth, which numbered seven, and to them they delivered, as best they could, the lecture they had heard on the previous night, repeating such of the experiments as the simple apparatus and reagents they were able to purchase enabled them to do. The lecturer attended one of their meetings at the end of the term, examined the students, and found they had acquired a sound knowledge of the subject so far, and the Backworth Students' Association—all miners—is now an institution, small, it is true, but containing the right material. They want to buy a microscope, for the use of the proposed summer class, and would doubtless like to see a qualified lecturer a little oftener. These Cambridge Local Lectures would have collapsed last Christmas if the Rev. T. J. Lawrence had not collected about £150, mostly in Cambridge, which was forwarded to the Miners' Committee, for the expenses of lectures to be delivered in the larger villages or small towns.

During the past ten years 600 courses of Cambridge Local Lectures have been delivered, with an average attendance of 100 students at each course, and the various towns have subscribed a total amount of upwards of £25,000 towards the expenses. In order to give greater continuity and system to the local examinations and lectures conducted by the syndicate of the University, it is proposed to grant to students in any town where there is no affiliated college, all the privileges granted to those who attend the lectures of the syndicate, under certain guarantees of regularity of study.

Mr. Mellard Reade's presidential address to the Liverpool Geological Society has been reprinted in the form of a pamphlet entitled "Denudation of the two Americas." The essay may be regarded as a sequel to the address in which he discussed the effects of chemical denudation as a geological agent. He insists strongly on the importance of applying quantitative methods to the study of geological phenomena. In the present paper he calculates the amount of solid matter removed in river-water from the surface of some of the principal river-basins of America. Mr. Reade thinks that the matter which exists in chemical solution in river-water has more importance as a factor in the reconstruction of the earth than is generally recognised by geologists.

The balloon contest at the Alexandra Palace is to take place some day this month at 5 p.m., but the balloons must be deposited in the "shelter" which has been erected for forty-eight hours before the start. The prize offered by the members of the Aëronautical Society is £25 for the nearest certified approach by actual descent to a given goal, and that is supplemented by the Alexandra Palace prize of £25 if the aëronaut descends within two miles of the goal.

At a meeting of the Leicester branch of the Amalgamated Society of Railway Servants held last week, attention was directed to letters in the engineering and mechanical papers relating to iron and steel crank axles, when a resolution was agreed to—"That this meeting sees no reason to alter the decision come to by the debating committee, as we are still of opinion that iron axles are far preferable, and more safe to the public and railway servants."

At the meeting of the San Francisco Microscopical Society, May 13, President Mouser in the chair and a large company present, Dr. J. H. Stallard demonstrated the method of cutting thin sections of delicate animal tissues by the so-called "freezing process." The section-cutter used by the doctor was the "ether spray microtome," in which the tissue to be cut is placed on a small zinc receptacle, into which, by a simple contrivance, a continuous spray of ether is injected. The rapid evaporation of this creates such an intense degree of cold that the tissue is frozen solid in about one minute, and then can be readily cut by a section-cutter sliding over two horizontal glass plates. The piece of tissue having been thoroughly soaked in a strong gum solution does not show a crystalline structure when frozen (as would be the case if it were permeated only with water), but cuts like cheese. It is claimed as a special advantage that very delicate organs, such as the retina, lung tissue, &c., which are so liable to be torn by the ordinary process of imbedding in paraffin or other fats, can be readily cut by the freezing method without being damaged. The tissue employed in the demonstration was a specimen of morbid liver, in the state known as "cirrhosis," and upon examining the sections under the microscope, the abnormal development of connective tissue and the characteristic fibroplastic corpuscles were well shown. Mr. Henry C. Hyde called the attention of the meeting to a subject of great practical importance to microscopists—viz., the comparative advantages and disadvantages of the various forms of "Camera-lucidas" or drawing prisms. Specimens of the Wollaston, Beale Neutral Tint, Nachet, Zentmayer, Grunow, Swift, Zeiss, and Schröder prisms were exhibited, and their respective peculiarities of structure and performance concisely and clearly set forth. An animated discussion followed, and great interest was shown in the subject. On May 21 the Society held its annual reception, and Irving Hall was thronged with an assemblage of delighted visitors. The members vied with one another in putting before their visitors the most attractive objects; but a slide exhibiting the electric spark seems to have been the chief novelty. It was shown in the collection by Mr. C. W. Banks. The terminals of eight fine wires from an induction coil were brought almost into contact, on a specially-prepared vulcanised rubber slide. The electric current, in leaping from one terminal to another, presented a most beautiful appearance. A halo of light played about the end of each wire, while a stream of richly-coloured violet light of ever-varying intensity connected each pair of terminals. By interposing a film of soot, the current was apparently deflected from a straight into a zigzag course, while a brilliant shower of intensely white sparks shot over the field of view. Mr. A. H. Breckenfeld exhibited the beautiful rosette-form crystals of kinate of quinia, by polarised light, and also two slides of gold dust, the first being from river sand, showing, in its rounded grains, the effects of the wear of water and sand, while the other (sweepings from coin trays) showed the characteristically flat scales which are the invariable result of the attrition of gold coins.

Herr Bohlig has discovered that boiling water will dissolve alkaline silicate from new glass vessels. It is not a new discovery, but Herr Bohlig has ascertained the amount, and finds that in two seconds 100 cubic centimètres of boiling water in a new flask dissolved as much alkaline silicate as would neutralise ·1cc. of solution of oxalic acid containing ·1 gramme per litre. From old glass vessels no appreciable amount of silicate is dissolved.

Some time ago Mr. Bayley showed that when drops of various solutions are allowed to fall on to filter paper, the salt which was in solution in many cases remains in the centre, and a water ring extends around it. Mr. J. U. Lloyd has extended these observations and a notice of them has been given in the *Chemical News*. He has observed the distances to which various substances in aqueous solutions extend on pieces of blotting paper, dipped into the solutions, before they are left behind by the water. Great differences were noticed in the length to which different salts thus travelled. Mixtures of salts were also examined; in some cases one salt passes on, leaving the other completely behind. Thus a solution of quinine and berberine sulphates was separated by the method described; the former salt passed on through the paper after the progress of the latter had quite ceased. Dilute sulphuric acid behaved similarly; pure water alone passed onwards. In the case of simple salts dissolved in water, the rule appears to be that the more dilute the solution the quicker is the separation into salt and water.

At a recent meeting of the Paris Academy of Sciences a paper was read "On a Method of Determining and Recording the Charge of Electric Accumulators," by MM. A. Crova and P. Garbe. The authors claim to have discovered a means of determining and automatically recording the exact amount of energy stored in accumulators, and so regulating the discharge as to be able to ascertain the quantity still held in reserve at any given moment. The apparatus used were of the Planté type as modified by Faure.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. Passmore Edwards.

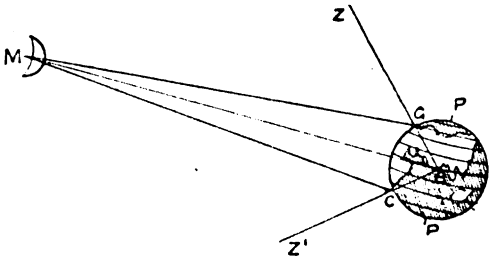
⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

## OH, WATER COMET!—FINDING THE MOON'S DISTANCE—WHAT IS "CREATION"?—TIME AND DIVIDING OF TIME—COMING ROUND—TESTS FOR A 5in. OBJECT-GLASS—A LARGE TELESCOPE FOR THE ROYAL OBSERVATORY—THE NEW TIME-TABLES OF VENUS.

[24365.]—Did "J. D. S." (letter 24312, p. 301), who talks about comets being icebergs!! ever hear that an overwhelming proportion of the comets so far examined by the spectroscope, have been found to be composed of some form of hydrocarbon, and that in the very rare cases in which a different spectrum has been exhibited, no trace of aqueous vapour in any form has ever been seen? In the existing state of our knowledge an icy or watery comet is sheer nonsense. Besides, how long would it be ere the vapour of water in space would seriously retard the planets in their orbits, and perceptibly shorten their times of revolution?

Inasmuch as "Essex Clod" (letter 24315, p. 301) has obviously a sufficient rudimentary idea of plane trigonometry to enable him to understand the method of determining the Moon's distance from the earth; I trust that the following description of the mode of proceeding will render it intelligible to him.



Here E represents the earth and M the moon; and G and C the observatories at Greenwich and at the Cape of Good Hope respectively, which, to simplify my explanation, are supposed to be on the same meridian. Very well, then: the observer at Greenwich notes the angular distance of the moon from the zenith; that is, the angle Z G M, while the man at the Cape simultaneously observes the angular distance of the moon from his zenith, Z′ C M. Hence evidently we get at once the angles G M E and C M E; in other words, the parallaxes of the moon at G and C respectively. Of course, the latitudes of the Greenwich and Cape observatories are accurately known, as is the angle G E C = their sum, the length of G E and C E radii of the earth being also rigidly ascertained; so here we have all the data needful to calculate G M, E M, or C M. In practice the problem is rather more complicated, as Greenwich and the Cape differ something like an hour and fourteen minutes in longitude, and an allowance has to be made for the motion of the moon during that interval. Moreover, the earth not being spherical, her radii differ in different places; for which reason the equatorial radius is taken as the unit in the final computation of the lunar parallax. Her distance once ascertained, the determination of her size follows as a matter of course.

As "Creation" is apparently a very elastic term, as employed by "H. B. F." (letter 24329, p. 304), I should like to ask him whether an Albino, born of normally constituted parents, is "created"; and, further, whether the same thing can be predicated of the curiously-changed forms of mollusca which descend from salt-water species, as the water from physical causes becomes merely brackish, or *vice versâ?*

The letter of "Lavant" (24333, p. 304) might have been epitomised in the dictum of the dustman *re* Emigration: "What I say about Hemigration is this 'ere. It's no use a man a hemigratin' unless he's got lots of money: and if he *has* got lots of money, wot does he want to leave Hingland at all for!" Surely this is scarcely a caricature of the arguments (?) of your correspondent.

Since Mr. Bird (reply 54698, p. 305) fails to give any reference to the letter or letters of mine on which he is so severe, I rather fail to follow him, the more especially as I do not remember commenting on the American misuse of the word "around." At any rate, that word is a solecism in more than one of his quotations from English writers. "He will then perceive above and around him a vast concave hemispherical vault"; and "Agencies at work around us," are perfectly pure and good English; while, on the other hand, "revolving around the sun," and "the equatoreal telescope turning around its polar axis," are extremely ungraceful, if not absolutely ungrammatical, forms of expression. Besides, two wrongs do not make one right. Finally, in expressing my gratitude to Mr. Bird for his kind advice to "read English works on astronomy," I would humbly venture to express my belief that I am familiar with the contents of every one worthy of perusal that has been published in this country (to say nothing of Newcomb's, Holden's, Chauvenet's, Loomis's books, &c.), and that if your correspondent will favour me with the name of one that I have *not* read, I will address myself to its perusal straightway.

In reply to "H. A." (query 56774, p. 311), the *minimum visibile* of a 5in. object-glass is Argelander's 12·7 magnitude (this lies between Smyth's 15th and 16th mags.), and its theoretical separating power for a pair of equal stars each of the 6th mag., is 0·91″. Knowing this, my querist can select objects for himself from "Celestial Objects for Common Telescopes," as tests for his instrument. In every case in which the object given in Webb appears in the "Bedford Catalogue, "Smyth's magnitudes, are retained, *vide* pp. 212 and 213. "H. A." may try ξ Scorpii, τ Ophiuchi, 110 Herculis, δ Cygni, $\epsilon^1$ and $\epsilon^2$ Lyræ (for the stars between the two pairs); the nebula 57 M. Lyræ, for stars on preceding edge, and for one following it. None of these (save perhaps 110 Herculis) are actually crucial tests; but it requires a good object-glass to show them.

It is very much to be hoped that Mr. Christie will obtain the necessary funds from the Government for the construction of the 28in. achromatic, on the need for which he insisted at the conclusion of his report at the recent Greenwich Visitation (*vide* p. 319). Albeit the National expenditure has recently "advanced by leaps and bounds," when one reflects how wickedly money has been wasted for the benefit of the ring at South Kensington, it does seem as though £3,500 might well and legitimately be devoted to the provision of an instrument worthy of the Royal Observatory, and which would certainly be employed for the purpose of advancing astronomical science, and not merely the interests of any person or persons. In a case of this sort, it does behove England to be on an equality with other nations in her instrumental appliances, and I trust to hear soon that the suggestion of the Astronomer Royal has been acceded to.

In let. (24356), "The New Time," p. 325, Mr. Hopkins quotes from a former one by "Conservative," concerning the inconvenience of a series of observations of phenomena of Jupiter's satellites being noted as occurring some on one day and some on the next. I wonder whether Mr. Hopkins ever heard of a solar eclipse beginning before noon and finishing after it; and if so—employing the present astronomical day of the *Nautical Almanac*—how he proposes to surmount this identical difficulty then? Referring again to your Report on p. 319, I would ask Mr. Hopkins to read, mark, learn, and inwardly digest what is there said on this subject. "The change from astronomical to civil reckoning has also been made in all the internal work of the Observatory, and has been carried out without any difficulty," &c.

In reply to "J. H. T." (query 56816, p. 333), I know of no later or better tables of Venus than those of Le Verrier.

**A Fellow of the Royal Astronomical Society.**

## THE REV. PREBENDARY WEBB—SUN-SPOTS.

[24366.]—Like your excellent correspondent "A Fellow of the Royal Astronomical Society," it was with feelings of profound grief I read the paragraph beginning your "Scientific News" (p. 275) announcing the death of the Rev. Prebendary Webb.

As I happen to be one of those mentioned by your correspondent, "who feel that in Mr. Webb they have lost a personal friend, albeit they may never in this life have seen his face," I may be allowed to add a few words about our departed friend, having enjoyed his confidence during a correspondence of nearly 14 years, and I looked on myself as a humble pupil of his in observational astronomy, for in my earlier beginnings he most kindly assisted me with invaluable hints and suggestions, and helped me over many difficulties with his experience of half a century. I am sure that many amateur observers over the world have, in the same way, received his kindly help in matters which could not well be inserted in his "Celestial Objects for Common Telescopes"—otherwise it would have proved a cumbersome volume indeed. Although his time was much taken up with attending to astronomical studies, I believe he conscientiously attended to his parochial duties through a largely scattered parish.

In September last he lost his dear wife, whose demise he announced to me in a most affecting letter, too sacred to touch on here, and her death, no doubt, hastened the departure of the loving and gentle spirit of one who had nearly reached a decade beyond the allotted span of life mentioned by the Psalmist. His loss will be greatly felt by astronomers and observers throughout the world, and the void will not easily be filled. On whom will his mantle fall?

Mr. D. Booth (letter 24314, p. 301) refers to a very large sunspot observed on May 25, and the portion he describes as the "nucleus" is evidently what is known as the umbra, or Dawes' "cloudy stratum," in which the late Mr. Dawes detected a black spot, or nucleus proper, using his improved eyepiece (vide *Monthly Notices* R.A.S., Vol. XII. p. 169). The sunspot mentioned by Mr. Booth is probably the one I observed on May 31, when past the sun's central meridian. It was divided by one of the well-known "bridges," and it was interesting to me as being one of the few spots in which I have seen the black nucleus with the ordinary Hodgson prism eyepiece. I remarked that the nuclei were not central in the umbræ, but were on the *s. p.* sides, and were quite black, whilst the umbræ were in comparison with the bright photosphere, like the crape-ring of Saturn relative to the bright ring. I did not notice any colour in the umbræ; but the violet tinge mentioned by Mr. Booth as seen on the 25th might be caused by the outstanding spectrum of the o.g., or if the image were put slightly inside of focus.

However, there are observations on record of the umbræ being seen slightly coloured, as cited in Webb's "Celestial Objects" 4th edition. Two large and interesting spots are at present crossing the sun's disc.

Belfast, June 9. **Isaac W. Ward.**

## NOTES ON SOME RED STARS.

[24367.]—In letter 24339 (p. 322) the Rev. T. E. Espin directs attention to certain red stars from Birmingham's catalogue. As I happen to have also observed some of these objects during the past season with my 11¼in. Calver, my notes may be of interest for purposes of comparison.

B. 135 Gem. Ruddy orange. March 1, 1815.

B. 148 Aur. Orange-red, very fine colour. Jan. 24, 1885.

B. 165 Mon. Really fine colour, nearly crimson. Feb. 9, 1885.

B. 166 Can. Maj. Orange. Feb. 2, 1885.

B. 248 Hyd. Deep red, good colour, but low. March 7, 1885.

B. 277 Virg. Almost scarlet, really splendid colour. April 11, 1885.

B. 328 Boöt. Orange-red, about 7½ mag. April 19, 1885.

B. 448 Lyr. Fiery red, almost crimson—superb colour. May 10, 1885.

B. 458 Lyr. Pale red, about 8½ mag., poor colour when compared with the previous object. May 10, 1885.

In addition to the foregoing, here are a few others in which I have found the colours good. The positions are taken from Birmingham's catalogue, and they are for epoch 1880.

B. 4 And. 0h. 13m. 34s.: + 44° 2·6′. Nov. 29, 1884. Almost vermilion, fine colour, though small.

* B. 94 Lep. 4h. 54m. 9s.: − 14° 59·2′. Dec. 14, 1884. Magnificent colour, vivid ruby; about 8½ mag.

B. 120 Tauri. 5h. 37m. 53s.: + 24° 22·0′. Jan. 10, 1885. Fine colour, like a bit of live coal; about 8 mag.

B. 121 Tauri. 5h. 38m. 30s.: + 20° 38·1′. Jan. 10, 1885. Fine orange-red, pretty good colour.

B. 123 Aur. 5h. 40m. 25s.: + 30° 34·8′. Jan. 11, 21, 1885. Fiery red; estimated 8 mag.

† B. 228 Leon. 9h. 41m. 7s.: + 11° 59·2′. March 15, 1885. Fiery red, splendid object; about 8 mag.

B. 521 Cyg. 19h. 53m. 18s.: + 43° 56·0′. Jan. 6, 1885. Small, but splendid colour—like a drop of blood.

B. 592 Cyg. 21h. 38m. 18s.: + 37° 28·0′. Jan. 7, 1885. Orange vermilion, rich colour.

* Also R. Leporis. † Also R. Leonis.

There is one object which I failed to identify as a *red* star—B. Add 27 Gem. (6h. 12m. 6s.: + 23° 19′). On March 1, 1885, I looked carefully for it, and made the following entry: "white—no coloured star here." I feel curious to know whether Mr. Espin or anyone else has seen it.

With regard to 60 Leonis, the entry in my notebook stands thus: "greenish yellow—5 mag.—March 22, 1878." And for 61 Leonis: "fine orange—5 mag.—March 13, 1878." I think the discrepancy concerning the first-named object is probably due to one of two causes—either to "personal colour equation" on the part of Schmidt (and it cannot be denied that this celebrated observer had a partiality, like Sir W. Herschel, for red tints), or to a real change in the colour of the star itself, and this, despite its seeming improbability, I am almost convinced does occur in some cases that have come under my own observation. It is, however, of little use to compare observations made by various observers at different times, without knowing more about their individual peculiarities in the estimation of colour. Of course, those made by the same observer on different occasions are less likely to be affected by this source of error. Still, it is much to be desired that some instrumental method of registering star colours could be devised, which would do away with the present uncertain state of things.

June 12. **W. S. Franks.**

P.S.—Since the foregoing was written, I have looked for B. 437, but without success. I saw the white star mentioned by Mr. Espin, but there is no red star near the place, unless very small indeed. It might be a long-period variable, possibly; but more likely the position given by Secchi is in error.

**W. S. F.**

## B. 147.

[24368.]—With reference to Mr. Espin's remark on this suspected variable (letter 24339), I may say that some years since I suspected that there was some confusion in the observations of B. 147 and LL. 12104 (H.P. 1189), and early in 1883, when collecting materials for my catalogue, I wrote to the late Mr. Birmingham on the subject, and in his reply, dated 24th May, 1883, he said that he had then no time to look up his notes, but would do so as soon as possible. I never heard from him since. He added, however, "I have no doubt of the variability of 147 Red Cat." On March 12, 1885, I estimated it 7·6m. in a clear, moonless sky (see p. 413 of my catalogue), my comparison stars being W.B. 536 (6·7m. Gould, which lies about midway between B. 147 and H.P. 1189) and LL. 12214 (7·0 Gould). On that date I estimated B. 147 about six steps fainter than the latter star. I could not have made any mistake in the identification of B. 147, as it is a tolerably isolated star, lying about 2° *n.f.* the 5m. star 10 Monocerotis.

June 15. **J. E. Gore.**

## H (G.C.) 2091 — THE SEPARATION OF DOUBLE STARS—TESTS FOR 5in. REFRACTOR — RED STARS — DOUBLE STARS.

[24369.]—I am much obliged to Mr. Tarrant (letter 24271, p. 276) for the care and trouble he has taken in looking up H (G.C.) 2091. I have found since writing letter 23999, the following observations of this interesting object with the Harvard refractor: "1868. January 24: Star 14 mag, nebulous and north of star 11 mag. Place of nebulous star with respect to the other 9 82°: 17·12″. No third star."

May I ask "A Fellow of the Royal Astronomical Society" where I can find Dallmeyer's formula, to which he refers in letter 24307, p. 300. I can only find the title of one paper of his in the Royal Society's Catalogue of Scientific Papers, and the formula in question is not in that one. Apropos of the diameters of star discs, I should like "F.R.A.S." to read Mr. Stone's paper in *Monthly Notices*, XXVI. p. 45; and Professor Pritchard's remarks thereon on page 47.

Unquestionably, Dawes's formula for the separating power of a telescope needs revision, as I have already suggested in the English Mechanic for July 14th, 1882 (letter 20263). Σ. made many experiments with artificial double stars at Dorpat, and he says of the separating power of the 9·56in. refractor, "Isdem stellis ita vero dispositis, ut centra 0·385″ et peripheriæ 0·085″ distent, in telescopio nostro stellam conspicimus duplicem distincte sejunctam." The climate of Dorpat is by no means favourable for astronomical work, and the o.g. was mounted in a deal tube on a wooden stand, and would certainly be inferior in defining power to a modern first-class o.g. of the same aperture. Surely an object-glass by Clark, for instance, properly mounted and erected in the highlands of California or Colorado, might be expected to perform better than the Fraunhofer at Dorpat. Dawes's formula applies to sixth-magnitude stars, as seen with an aperture of 1in., when the atmospheric circumstances are *moderately* favourable, and I am not aware that he used any larger refractor than his own of $3\frac{6}{10}$in. aperture when making the experiments upon which that formula was founded. He says, "As the diameter of the discs does not increase in proportion to the power, the separability of all magnitudes is nearly the same, provided the state of the air is such as to bear well the increase of power." This is certainly an oversight, as though a good 4½in. would separate two 6 mag. stars one second asunder, yet no 4½in. in existence would split a pair of 11 mag. stars at that distance.

"H. A." (query 56774, page 311) will find the following objects good tests for a 5in. refractor. The stars given are either all in Webb, or are naked-eye objects. As Franks has found that a 5in. refractor is about equal in light-grasping power to a 6½in. silvered-glass Newtonian, he can also examine the light tests given on page 188. The mags. are expressed in Σ's scale.

It is extremely difficult to give any formula for ascertaining the light-grasping power of any telescope, as that depends so much on the observer, and scales and light ratios differ so widely.

With Dawes's formula (*Monthly Notices*, XI. p. 189), the *minimum visibile* with a 5·0in. achr. would be about 11·1 Σ.; with Johnson's (Radcliffe Obsns. XII. Appendix), the faintest star would be 11·8 mag.; with the formula given in Newcomb and Holden's "Astronomy," p. 419, this would be as low as 12·5 Σ. "F. R. A. S." has given Carrington's and Pogson's formulæ on p. 77 of the present volume of the ENGLISH MECHANIC. Struve himself fixed the *minimum visibile* in the 9·6in. at Dorpat at 12·4 mag. in his scale, which, according to Newcomb and Holden or Pogson, would be the faintest visible in a telescope of exactly half that aperture; the faintest visible in the Dorpat refractor being 13·9, according to their formula. I have no doubt that such an observer as Mr. Ward would see a 12·5 mag. Σ. without much difficulty in a 5in. achromatic, indeed, he has discovered stars nearly, if not quite, as faint as this, with 4⅓in. aperture; but so much depends on the eyesight and experience of each individual observer, that any tests of this kind are unsatisfactory. The mags. of Σ's objects in Mr. Webb's book are given in Σ.'s scale.

Mr. Espin (letter 24339, page 322) will find observations of some of the red stars referred to by him in the first volume of the Washburn Observations, pages 161–163. 60 Leonis is given correctly in Schmidt's paper, "Ueber die Farben der Fixsterne" (*Ast. Nach.* No. 1902), but he does not actually say it is red; but only includes it in a list of reddish yellow stars, the four first of which are ι Ceti, δ Andromedæ, *a* Cassiopeiæ, and β Ceti. I have no doubt that Secchi's place of his new red star is in error, as such mistakes are very common in Secchi's double-star observations. The error may amount to an hour or more in R A, or 10° or 20° in Decl. The place for 1880 0 of Secchi's star from his data in "Le Stelle" would be 18h. 15m. 5s. + 25° 1 9′, exactly the same as Birmingham gives.

I am glad that Mr. Gaudibert (letter 24342) has succeeded in finding the cause of his certainly somewhat puzzling observations. I felt sure that something must have been amiss, as his success in seeing such very difficult pairs, while he failed to perceive much easier ones, was inexplicable. I presume that the observations in letter 24342 were made *before* he adjusted his mirror. The following are the latest observations of the stars he mentions:—

Gledhill 430. Σ. 1781. Eng. 264 5° : 1·36" : (7ⁿ) 1883 97 nearly equal.

The suspected double appears to be W B. (2) XII. 1086, the place of which for 1885 0 is XIIh. 55m. 58s. + 21° 53′ 25". It is not known to me as a double star. Bessel and Argelander both rate it 7·0 mag.

γ Coronæ. The position angle was not very different from 120° in June, 1882, according to Do.'s elements, but the distance was certainly under 0 15".

β 612. Hall gives 63 3° : 0 21" : 1879 48. β 619. De. 174·0° : 0 38" : 1878 46. $\mu^2$ Boötis. The angle is now about 110°, and the distance 0 85".

Gledhill 465. Σ. 1879. Eng. 209 4° : 0 31" : (7ⁿ) 1883·55. Gledhill 466. O.Σ. 285. Single Burnham, 15½in. power, 750, 1881·50. Gledhill 467. Σ. 1883. Eng. 259 0 : 0·88" : (5ⁿ) 1884·43. ξ Boötis. The angle is now about 263°, and the distance 3·5′. Gledhill 469. O.Σ. 287. Pe. 307·4° : 0·71" : 1883·50.

Gledhill 470. O.Σ 288. Seabroke 193·7° : 1·34" : 1880·55. Gledhill 494. O.Σ. 298. Sch. 7 5° : 0·33" : 1882·47 "ovale decisa." This is now wider. Doberck gives a period of 63 80 years, Dolgorukow of 70·26 years.

June 15th. **H. Sadler.**

## DISTANCE OF THE MOON.

[24370.]—SURELY "Essex Clod," letter 24316, can perceive that if the moon, on a certain day, appears from Colchester to pass south of a certain star, while she is seen, say from Capetown, to pass north of that same star, if both observations were accurate, their comparison would give us the ratios of both her diameter and distance to the distance between Colchester and Capetown. This is known to a furlong, and considerably exceeds her diameter.

In no month are any of the stars that she occults from us, occulted also from the Cape. Not only is she constantly hiding, from intermediate countries, stars that we see well north of her, and the Cape sees well south of her; but often does she eclipse the sun from Mediterranean or North African places centrally, and even totally, while neither is touched by eclipse here in England, nor in Cape Colony. The total eclipse, for which our astronomers visited Upper Egypt some years ago, was such a case. **E. L. G.**

## ASTRONOMICAL.

[24371.]—I HAVE no doubt every astronomical reader of the "E. M.," to whatever country he belongs, has felt the deepest sorrow in reading of the death of Mr. Webb. For my own part I fully endorse the paragraph, so very true, of "F.R.A.S.," in No. 1654 of your Journal. Through unfortunate circumstances I have been deprived of the privilege of his personal acquaintance, when, some years ago, we sought each other, without success, both in London and in Belgium. His "book" and some private letters from him will not fail to endear his souvenir to my heart. May I be permitted also to express my deepest sympathy for those he leaves behind.

If Mr. E. Holmes (letter 24310) will look at τ Boötis with a low power, I think he will not fail to see the *comes*. I held it steady last night, with about 100 on my 8½in. mirror; clouds not far.

In my letter (24342), B = β = Burnham, line 10, middle column, a full stop after "close."

**M. Gaudibert.**

[24372.]—MR. GAUDIBERT, some time ago, ascribed my failure to elongate γ Coronæ to my want of experience in observing close double stars. Apparently, from letter 24342, his success was due to bad adjustment of his mirror. It is fortunate he has found this out at last, for his elongations of pairs far beyond the theoretical limits of his aperture fairly staggered many observers. I could not understand how it was he failed with stars I saw, and succeeded with those quite beyond my eye and instrument. It is satisfactory to find he has had the courage to declare he has been wrong, which some of us might have hesitated to admit. If he will forgive one so inexperienced as myself giving advice to so practised an observer, I should like to tell him he need never be in doubt a second whether his telescope is in perfect adjustment or not. When he has made it as near as he can, let him point to a bright star; and when he has focussed with a high power, let him draw out his eyepiece so as to enlarge the focal image to a small ring of light. If there is the smallest imperfection, one side of this ring will be brighter than the other, looking like a ring with a badly-shaped star as an edge. But having found out his error, why has he gone on to elongate β 612 0·19"? His mirror must still be out a trifle.

His following sentences are to me a little mixed up.

I have twice estimated γ Coronæ this year near the P.A. Mr. Gaudibert gives. It is said to be double in the Bermerside refractor. Perhaps their o.g. is out of adjustment also. I am in a bad position, and possibly—nay, certainly—not provided with such perfect means; but I do not believe any 9in. instrument can possibly show it double at present, unless out of adjustment.

Will Mr. Gaudibert kindly say how he sees ζ Böotis at present? Does he get a disc of star in distance betwixt the components, or are the discs in contact? The measured distance puts it within reach of a 7in. instrument; but of course the mag. of the components is against the separation. Such an excellent mirror as Mr. Gaudibert's will, of course, surpass mine, but I can only just separate the components. Is not φ Draconis very close just now? Like Mr. Gaudibert, I have to remove my telescope every time I use it; but I long ago came to the conclusion it was a distinct advantage so to do, since it forced me to pay attention to the adjustments, and has given great command over them.

**Edwin Holmes.**

## LARGE METEOR.

[24373.]—A BRILLIANT meteor flashed forth from near to the star η Boötis on the 11th inst. at 21h. 42m. (new time), and took a direction of, almost, direct north to south for about 15°. It travelled slowly, and its duration was about five seconds. Its colour was similar to that of the star Vega, and it exceeded that star in magnitude by at least six times. It had no train of fire in its rear, and after the whitish light had disappeared, there was left, for an instant, a ruddy coloured orb travelling in the same path of the meteor.

5, Rownsley-street, Leeds. **D. Booth.**

## A NEW TELESCOPE FOR GREENWICH OBSERVATORY.

[24374.]—I NOTICE that, in your report of the Greenwich annual visitation (p. 319), the Astronomer Royal points out the necessity for a larger telescope at the Royal Observatory. It does seem anomalous that the oldest establishment of its kind in the world, and the official representative of the richest nation on the face of the globe, should be left behind in its instrumental appliances by many other Governments, and even by private individuals. Yet this is indeed the case, much to our national discredit. If we showed the same zeal to be foremost in science as we are in war, we should be more likely to avoid those inglorious struggles which bring feelings of shame and humiliation to every right thinking Englishman. If any other Power builds a monster gun or unwieldy ironclad a little bigger than our own, there is instantly a chorus of howls from our bellicose pessimists, and this nation is straightway doomed to destruction unless we beat them in turn. But with regard to our scientific priority, that is entirely a different matter, and we are content to play second fiddle to any other nation from whom we can borrow a scientific idea. Even Russia, whom we affect to despise as a semi-barbarous Power, leaves us hopelessly in the rear with respect to the instrumental equipment of her national observatory. About the cost of such a telescope as proposed by the Astronomer Royal there is, I think, some mistake in the figures, as £3,500 seems a remarkably low quotation for a 28in. refractor. Grubb's price for a 27in., complete, is £7,000, and I have reason to believe that his prices are considerably below those charged by the well-known American firm of Clark and Sons. Suppose we put it at £10,000, and an item like this would be a mere bagatelle to the richest Government on earth, who can throw away millions of money on warlike preparations which are worse than useless. And is the collective scientific enterprise of a vast nation like ours to be outdone by private persons, as at present it is? Let us hope not, for our own credit's sake. Whilst Republican Governments do not hesitate to apply public money for similar objects—and they spend it much more liberally than we do, too—it should not be said that Her Majesty's Government begrudge the paltry sum asked for by the Astronomer Royal in order that the Greenwich establishment may be as well provided with instruments as those of other countries.

**W. S. Franks.**

## THE RADIOMETER.

[24375.]—ALTHOUGH much has been written upon the Radiometer, there is one factor in relation to it which appears to have been hitherto quite overlooked—namely, the hygrometric influence of the atmosphere. The opinion generally entertained is, that the rays of heat, whether from a luminous source, such as the sun or a lamp, or from a non-luminous one, such as iron heated below redness, hot water, &c., act *directly* upon the instrument, being transmitted by the interstitial ether of the air and of the highly attenuated molecules within the bulb, and the light or heat waves corresponding to such radiations being rendered sensible by the absorption of them, and consequent radiation, by the blackened surfaces of the rotating vanes. It is, of course, implied that the shorter light-waves are thus converted into the longer heat-waves. This view of the phenomena would probably be correct if the air through which the rays of heat pass were a strictly homogeneous medium, or simply composed of nitrogen and oxygen, for then it would be almost perfectly transparent to thermal radiations, and there would consequently be no sensible absorption of them in passing through it; but it must be remembered that such is never the case, the air at all temperatures being more or less charged with invisible aqueous vapour, and containing also smaller and variable quantities of carbonic acid and ammonia (the latter gas being likewise one of the most powerful of the gaseous absorbents of radiant heat); but, taking into consideration only the aqueous vapour, it has been proved by Professor Tyndall to exert so much potency as an absorbent of radiant heat that, though its average amount in the atmosphere is less than 0·5 per cent. were it to be entirely withdrawn from it, all vegetation upon the earth's surface would probably be destroyed by cold even in a single night.

It is clear then, I think, that the rotations of the radiometer can in nowise be regarded as indicating the initial energy of the radiations acting upon it, whether solar or terrestrial, inasmuch as the secondary radiations from the aqueous vapour, though theoretically equal to the absorbing, can never represent the latter fully in amount, much energy being inevitably lost in the surrounding space.

The radiometer must accordingly, I conceive, be regarded as under the influence of *two* sets of radiations—the primary, or those unabsorbed by foreign gases or vapours existing in the air or other medium through which they pass; and the secondary, or those absorbed or intercepted by such gases or vapours, and which are given out again by them, and thus serve to act indirectly upon the instrument.

How far the revolutions of the radiometer could be made available in meteorological observations for ascertaining the comparative amount of aqueous vapour in the atmosphere, according to this principle of secondary radiation, is, perhaps, impossible to predict; but, as through perfectly dry and pure air heat-radiations of all kinds pass, as Prof. Tyndall has shown, with hardly any appreciable absorption, and if the quantity of radiant heat when absorbed be, generally speaking, proportionate to that of the invisible vapour in the air, we seem to have a direct relation established between the secondary radiations and the movements of the instrument. And here, I may mention, that I have occasionally in damp and cloudy weather found my radiometer comparatively active, although the solar light, under such conditions, has to the eye been very weak. **W. H. O.**

---

## "MIND AND MOTION."

[24376.]—The Rede lecture by Mr. Romanes, of which a summary is given in the "E.M." might naturally be expected to work on the lines of a reconcilement of the old and new modes of thought, when we consider the place where it was delivered. The method of defence adopted by the cuttlefish and his ink-bag is well known, and has often been taken as a model in such reconciliations.

But probably all Mr. Romanes' statements are not to be taken seriously, but must be considered merely as morsels of jam for reclacitrant children, who have to take nasty medicine.

It appears from the lecture that "Physiology necessarily leads to materialism." This result, however, is to be corrected by an appeal to metaphysics. "All our knowledge of matter and motion is merely a knowledge of mind-modifications"; whence the conclusion is drawn that, so far as we are concerned, mind exists before matter. This is certainly a complete *non sequitur*, even if intelligible.

It cannot mean that matter and motion have no objective existence, being merely mental phenomena; because in that case the conflict with materialism would be nothing else than the laborious churning of a vacuum. Nor can it mean that while matter really existed before mind, that the reverse is the case "so far as we are concerned," which is meaningless.

Nor can it mean that our minds existed and reasoned before we had bodies, much less before the existence of any matter at all, and if mind existed before matter, matter must have come into existence spontaneously, for according to Mr. Romanes, mind cannot produce matter any more than matter can produce mind. It is to be regretted that the reasoning demonstrating the deceptive character of physiology should be so obscure.

Materialism, I suppose, consists in supposing a causal connection between mind and brain action.

Spiritualism, I presume, supposes no causal connection—that is, none at all, for there can be no connection but what is causal.

The latter, according to Mr. Romanes, is almost (why not quite or more so?—is this a morsel of jam?) as absurd as the former. The doctrine of the conservation of energy is said to demonstrate this. Here, in my opinion, is another *non-sequitur.* The destruction of energy or the creation of energy would be certainly a violation of the received doctrine; but that there should be a causal connection without such changes between certain energetic conditions of matter and mind, although not included in the conservation of energy, is not in contradiction, but rather a supplement thereto.

In this matter I opine we cannot decide à priori, but must submit to be taught by observation—that is, by physiology. If (which I do not admit) physiology and conservation of energy were found in opposition, we should, indeed, be in a dilemma, for both have the same basis, namely, observation and experiment, and that alone; but if one had to succumb, it would, I think, be the conservation of energy, for the case would be similar to the theory of gravity failing to give any account of eclipses which happened when they were not predicted and never when they were. In this case we should say the theory of gravity was in fault, and not that unpredicted but observed eclipses really had not taken place because contrary to our theory.

So cogent, indeed, are the facts, that the lecturer who is arguing against the causal connection in question has to admit it in express words; but, of course, before doing this the cuttlefish's inkbag had to be emptied in making the statements that the "antithesis between subject and object is but apparent, and that brain changes and corresponding [what is meant by corresponding if there be no causal connection?] mind changes are not two changes, but one." This can only mean that subject and object, that is, all objects are one, and that there is no distinction between the brain and mind. This would imply personally to the present writer, that there is no distinction between his mind and the whole so-called objective universe, including all other so-called subjects, who would, to him, be merely objects, including Mr. Romanes himself and his lecture.

Under such circumstances, there could hardly be any dispute or any conclusion come to about anything or any form of theism.

After this the lecturer thinks it safe to contradict what his lecture is intended to demonstrate, and assert that "intelligent volition is a true cause of bodily movement, and that volition could not take place without brain action, and *vice versâ*!" This is said to satisfy the freewill hypothesis as well as the determinist. It would appear that it was only by a sort of recantation that Mr. Romanes could kill two birds with one stone, or, rather kill one bird and preserve the life of another. To destroy materialism it was necessary to show that brain action, or motion, could not cause mind, which implies that mind-action could not cause motion; but the "freewill hypothesis," which was not to be destroyed absolutely, required the possibility of this, so that a seat between two stools had to be accepted. The proverbial result of such a position need not be mentioned.

The result of considerations such as those presented in the lecture, is to lead to some new religion which will have the merit (it appears to be a merit in the view of the lecturer) of being more "vague"—that is, more unintelligible, than the older forms.

The creed of this new religion—if it is to have one at all—will not probably require for its acceptance much exercise of faith, if, as one may gather, it "must of necessity speak the language of Agnosticism." That is, it will not express a belief in anything whatever. **W. C. E.**

---

## ASTATIC GALVANOMETER.

[24377.]—Several errors have slipped into the description in the last number but one of the above galvanometer. The stand should be 6in., not 8in. in diameter. After the third sentence in the second paragraph read as follows: The screws work in three equidistant holes, drilled and tapped near the edge of the stand. Two binding screws are fixed between two of these levelling screws, and opposite to the brass support described below.

97, Crawford-street, W. **G. Bowron.**

---

## GAS-ENGINES.

[24378.]—I do not profess to know anything about gas-engines, and am entirely unable to discuss the respective merits of different sorts. As, however, I have been engaged in fitting one up for my own use at different times since the beginning of February, and think now that I have ascertained what may really be expected of it, and observing that there are inquiries about such a thing in the pages of the English Mechanic, I will give a few particulars of the one I have. It stands on a base of about 26in. by 22in.; cylinder upright, 3½in. bore; stroke, 10in.; weight altogether, with a single flywheel, just about 2cwt. I think a second 50lb. flywheel would improve it. Total height about 40in. or 42in. The explosion makes about as much noise (so I am told) as a Bischopp of like size would do, if there are any so small. The exhaust makes no noise at all, except at first starting cold; if the gas is properly regulated, and the hotter it gets the better.

I have had it working with a friction-brake pulling 2¼lb. at the end of a lever 15⅜in. long, and running 200 revolutions per minute, which makes an actually developed power of 4,000 foot-pounds, and that is pretty nearly as good a 1-man power as you will generally meet with. The quantity of gas consumed seems ridiculously small, as the sides of the gas bag (and a single one of about 4in. wide appears sufficient) hang down quite flabby and loose, as if the gas-supply were wire drawn before it got so far.

As I was determined that the engine should not prove a failure for want of workmanship, I made it all in superior style, taking about 200 hours over it, exclusive of the experiments that were afterwards made to ascertain its powers. Except improved ignition, it went right off at first trial as well as it does now. I could do another in half the time.

Anybody who would like to see it running can do so by applying at 100, Bolsover-street, where I myself obtained the castings, seven minutes' walk from the Langham Hotel, where it will remain probably for a month or six weeks. It has no piston-rod, no guide-bars, and no packing, and I may add, to disarm hypercriticism, not the slightest attempt at external finish anywhere, though inside as sound as a bell. **J. K. P.**

---

## THE NEW TIME.

[24379.]—The plan of printing railway and other time tables in thick and thin, or in black and red, type to indicate a.m. and p.m. is, I submit, no gain, but a loss. Persons habitually using such tables might remember which type referred to fore and which to after-noon; but the great bulk of the public, aware of a difference, would be worse off than they are now, for they would be in doubt which half of the twenty-four hours was represented by the distinctive type.

What objection there can be, except aversion to change, against adopting the new time, I cannot see. Once understood, all difficulties and mistakes are at an end; the system can be mastered in a minute. Surely no one will pretend that to add 12 to 1, 2, 3, &c., to obtain the new time, or to subtract the same number from 13, 14, 15, &c., to arrive at the old is beyond the intelligence of the age.

What would anyone think of dividing the foot, not into 12in., but into, say, six left and six right, so that 3in. would be 3in. left, and 9in. 3in. right? To be shown in print by changes in type or colour.

As regards Mr. Kloen's suggestion, the Editor points out a strong objection to it—from the printer's point of view; another remains, and that is that red figures on a white ground are not easily read in a feeble light.

The adoption of the new time would do away at a stroke with all uncertainty. It assimilates civil and astronomical time; it is a broad and simple way of dealing with the question. Change of type to preserve the old is a mere tinkering of it. As soon as time tables are issued in the new time all the supposed confusion will cease, and the public will only be surprised to find that they have adhered so long to an unscientific division of the day.

**Eye-Witness.**

---

## AUTOMATIC MUSICAL INSTRUMENTS.

[24380.]—I have taken in your paper since September last, and occasionally borrowed some from a friend of mine in August same year. I was glad to find some valuable information in your letters and articles touching on the automatic instrument made by Messrs. Wenham, Fryer, Child, Rock, "Vulcanite," "A. S. L.," "H. M., I. R." I am making an instrument myself on the blow system, consisting of five octaves. The reeds I am using are a set of broad bent reeds, a very powerful tone; in fact, the bellows are large enough for two sets and a half of reeds.

My first idea was of an instrument called the "Cabinetto" some years ago. I could not get a set of A. organ reeds at this time, so I used the above reeds for the purpose. I filed the plate slant at the sides to slide into the channels like the English concertina notes. The holes in the paper acted as valves. I had then to make a soundboard 3t. 4in. long by 12in. deep; the sound holes ranged from the bass ¾in. to ¼ square. The rollers were 3ft. 5in. in width to hold 600ft. of paper. The reeds were ½in. apart on the soundboard. When I got all ready for the rollers I found it would not act owing to the width of the paper, which used to tear, although the paper was a stout brown and glossy one side. So I dropped off going on with that class of instrument, which I think was very foolish of me to commence a large machine of that sort without any assistant. Hoping that I will see a sketch of some of our inventors on this subject, I wish to work the above with pallets and levers. My instrument was on the suction principle, but I see many letters in the "E. M." on this subject, and an article by Mr. Wenham. I think this gentleman's style would correspond with the 5-octave instrument that I intend to make, also thanking all our writers for their valuable letters on the matter, hoping that I will, after my great failure, receive some benefit from their ideas.

**Thomas Pugh.**

90, Great Homer-street, Liverpool.

## THE BREAKING OF AXLES.

[24381.]—I am extremely glad to notice that this important subject is now engaging the attention and consideration of your correspondents, and there can be no doubt that a full and fair discussion will bring to light much valuable information. "Midland Driver," p. 325, refers to steel axles, and asks for the mileage of each.

Upon reference to a statement drawn up by the Midland Railway Company to September 25th, 1884, I find that between January, 1874, and September, 1884, 172 steel crank axles, made by Messrs. Vickers, Sons, and Co., were put into service. Eight have been "broken," one (No. 73) taken out "defective," the others being at work.

| No. of engine. | Date put in service. | Miles run before failure. |
|---|---|---|
| 829. | 9 Jan., 1875. | 303,535. |
| 61. | 22 May, 1875. | 238,468. |
| 809. | 23 Jan., 1875. | 233,503. |
| 823. | 20 June, 1874. | 218,573. |
| 1104. | 18 Nov., 1874. | 150,984. |
| 63. | 31 July, 1875. | 131,603. |
| 1. | 19 Feb., 1876. | 47,447. |
| 9. | 26 Feb., 1876. | 37,524. |
| 73. | 29 April, 1876. | 27,132. |

With reference to "Midland Driver's" question relating to the crank axles taken out in the shops, I find that during the year 1883 the Great Northern Company took out 15·5 per cent. of defective axles, none being broken when running.

On the Midland Railway 2·4 per cent. broke when running, and 8·7 per cent. were taken out in the shops.

There can be no doubt that all railway companies are giving much more attention to periodical examinations than was formerly the case, and from several lines I have statements showing that this extra care is fast reducing the proportion of axles broken when running, and the number taken out in the shops is correspondingly increased.

**Clement E. Stretton,** Hon. Mem. A.S.R.S.

Leicester, June 13.

## CRANK AXLES.

[24382.]—One cannot read the letter of "Original Lockstitch" (24331) without seeing that he must have come to a rather hurried conclusion that it is impossible to find which way the grain is. No amount of hammering can destroy the grain, and Messrs. Linney and Lawson have shown how important it is to have the grain in the proper direction. Where do cranks break? is a question that "Lockstitch" has raised. 19 out of 20 go through the web, like the Penistone one; the 20th goes either in the crank-pin or any other part. The web is the fatal spot.

Perhaps "Lockstitch" would give the number of that Midland engine that he failed to detect the flaw on; as we might some of us remember the facts, and give some reasons for the same. Was it a steel or iron crank? There is a way, with an instrument, to find if a bar of iron is solid. Will any of "ours" refer to it in full?

**Iron Crank.**

[24383.]—Having read with interest several observations as to crank axles, a few notes may not be unacceptable. I was employed some years ago in a locomotive factory, and had opportunities of seeing fractured crank axles just taken out of the various engines. I kept a diary stating particulars of each fracture with a sketch of the exact part, and well remember of the twenty-five or thirty I had thus booked 90 per cent.—in fact, almost all—were fractures in the web or jaw of the crank. It was the general opinion of our best smiths that the iron was not so well solidified in the blocks forged for the cranks. I agree with one of your correspondents that the grain or fibre of the iron must to some extent be the short way of the iron in the web, and prove to be the inferior part of the forging. Hooping is no doubt an excellent thing. It will be obvious to most people that all crank shafts, marine or locomotive, are subject to a severe strain by the engines racing in the former, and surging in wet weather of the latter; in each case the jerk or grip of the work coming upon the lever of the shaft so suddenly as to deteriorate the nature of the iron in time.

West Hartlepool. **H. Casebourne.**

## HOW SHOULD CLOCKS STRIKE?

[24384.]—This question, on which you allowed me to make the following suggestion many years ago, seems quite independent of "the new time"; but yet, if rightly solved, would soon effect that superseding of "a.m." and "p.m.," which the "twenty-four o'clock" plans vainly aim at; and not only so, but simplify our way of expressing time-appointments much more. Your American correspondent, Mr. Woodside (letter 24345) makes now an approach to the same proposal. He makes his clocks strike only hourly, and only up to six, when they recommence, reducing the strokes per diem from the usual 156 to 84. It is impossible, he thinks, to make a mistake of six hours; but surely it is equally so, in all but the dead of night, to err by four hours. Why not, then, as I proposed, adopt from the mariners the full method into which the necessities of ship-life long ago drove them? Once an hour is not often enough to address the ear; but our "quarter-jacks," if not superfluously often, are at any rate ridiculously imperfect, by assuming every hearer to know what precise hour last struck. The half hour is the right interval at which to strike, as sailors discovered and settled centuries ago.

Now observe that all our public appointments are at either hours or half-hours. Even the starting of trains from their main termini will rarely be any exception to this. We do practically, then, in all our towns, make half-hours the general units, and appoint every meeting by these; or, as sailors say on shipboard, by "bells," only instead of their simple phrases "five bells" or "seven bells," we stick to our cumbrous "half-past two o'clock," and "half-past three o'clock."

Suppose Mr. Woodside now were to make his clocks, and persuade civilised Boston to make theirs, strike exactly like the mariners', half-hourly, and counting only up to eight (our present 12, and even 10, are absurdly high to count). The sailors compendious "eight bells," "two bells," &c., would soon supersede our cumbrous nomenclature in his "hub" city, as it long ago did in all ships. But of course they must, in print, distinguish the six watches by initials. Say *c* for cock-crowing, *m* for morning, *f* for forenoon, *a* for afternoon, *e* for evening, and *n* for night. Then observe how fully a single letter and single figure will suffice for all public appointments, and how much of our present printing they supersede.

*f* 7 instead of "11.30 a.m."
*n* 3 " 9.30 p.m."
*e* 5½ " 6.45 p.m."

or "a quarter to seven, p.m."

The power of the striking part of a clock need not be increased, as the odd numbers or the half-hours may be omitted in both the night watches, and the even numbers from the later one, reducing the daily strokes to 164, as easy nearly as the present 156.

Where a clock has quarter-jacks, of course retaining the use of all the bells will enable it amply to distinguish the new striking from the old. But where there is but one bell, the strokes should be *in pairs* (as sailors call them), far easier counted than when single; and only the one, at half-past 12, could ever be mistaken for the old "one o'clock."

Allow me a word on our "railway time," now carried in America to the *reductio ad absurdum* of *four* railway times—false time everywhere but on four particular meridians!—and a break of an hour whenever a train passes, who can tell where? at hundreds of petty stations. Assuredly the Celestials—if not wise enough to keep, as they have, the flowery land undefiled as yet by a railway—would have avoided this monstrous blunder. All that we ever needed, or Americans either, was two editions of the train-tables, one for officials and one for the public. The present ones ought, from the day Exeter was reached, or even Bristol, to have been confined to the hands of railway servants, and a translation of them printed for the public, by merely altering each figure from railway time to true local time. To aid in setting travellers' watches, the station clocks might have had a double minute hand, as was often proposed. However we shall make Greenwich time and Dublin time each serve for a whole island, and having set the Americans no example, they will have sooner or later, to discover this for themselves.

**E. L. G.**

## MATHEMATICS AND SCIENCE.

[24385.]—The letter of last week's issue on "Cramming in Physico-Mathematical Science" suggests a few remarks on the position which mathematics occupies towards science, and on the best way of acquiring a knowledge of those methods of calculation which are of importance to the scientific worker.

As our knowledge of a science becomes accurate and defined, and the mutual dependence of facts and theories is evolved, the value of mathematics as a weapon for the expression of these relations, and their numerical estimation, becomes more and more apparent. It is true that frequently the demand made on our powers of calculation may not overstep the bounds of arithmetic; but often the most elaborate processes of reasoning have to be brought to our aid if we are to attack a difficulty with success, and then we often find that the limits of our knowledge are determined by the limits of our mathematical penetration.

In astronomy, light, sound, &c., there are many interesting inquiries which can only be successfully promoted when the mathematics required have been first developed. The vortex theory of atoms progresses slowly for the same reason. Our advance in these, as in many other branches of science, awaits the advance of our methods of calculation.

The ordinary mathematical curriculum is so severe that most men shrink from it. What is wanted is a course of mathematics expressly designed for students of physical science, apart from those who wish to cultivate mathematics for itself. A year devoted to such a course would probably be more effective than three passed in going through the conventional stages where much time is given to subjects and parts of subjects, which are seldom of use in ordinary physical problems. Such a course need in no way be deficient in logical sequence. Many parts of algebra, trigonometry, co-ordinate geometry, and the calculus might thus be avoided without appreciably affecting their practical value for all scientific purposes.

It must not be forgotten that there always remains a very large number of persons who have neither the time nor the inclination for mathematical studies, though they may suffer great inconvenience if they are not to make use of the results of other people's. It is hard to be debarred from the use of formulæ because the proof cannot be comprehended, and there is no reason why this should be so. There is often a perfectly logical way of regarding formulæ as short summaries of fact which experiments show to be correct. Indeed, of all the calculations made the large majority are done by those who merely work by rule of thumb. Our ships are navigated over the whole world on this principle. Half a loaf is better than no bread, and in like manner a formula without the demonstration is better than no formula at all.

**Lewis Edmunds.**

10, King's Bench-walk.

## LEGAL REPLIES.

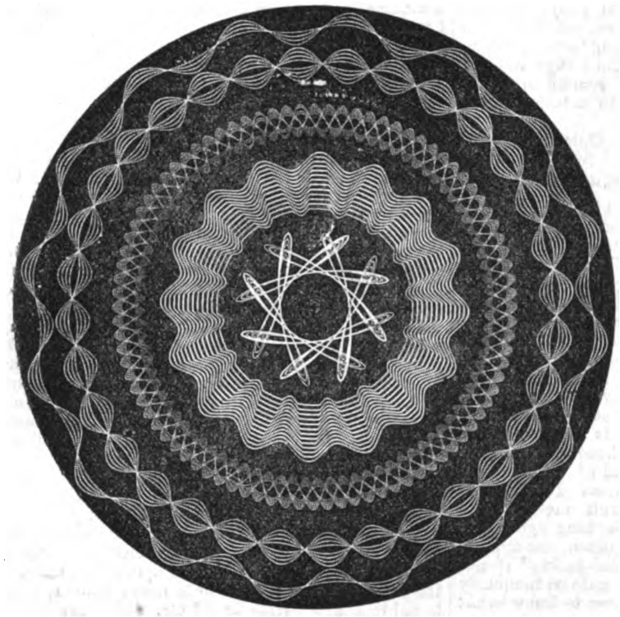
[24386.]—Lease (56641).—The lease should be conveyed, or, as it is properly called, assigned, by the mother to her daughters. I presume the widow has proved her husband's will, and so has the legal right to deal with the property. The assignment can either be by separate deed or by indorsement upon the existing lease. The former is generally the better plan. It should be properly drawn up, and as the stamp duty would only be 10s.—there being, I presume, no consideration but "natural love and affection," as we say—the cost might not be more than two or three guineas beyond the stamp, unless, of course, there is anything special in the matter.

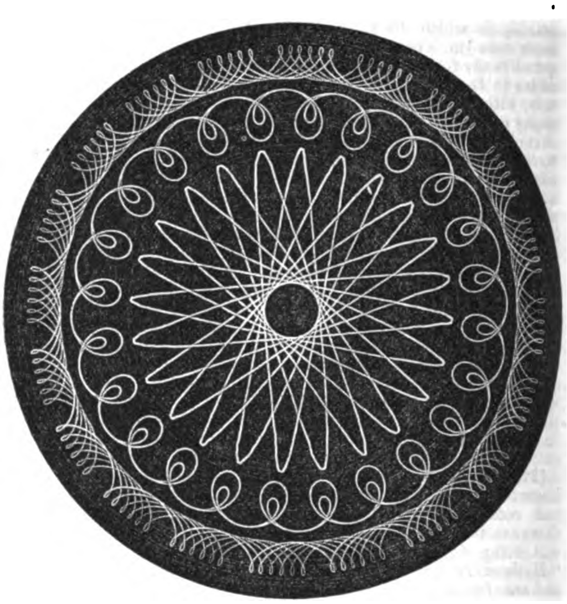
(56717.)—Will—Legacy—Age 25.—If A. by his will bequeathed a legacy to B., upon his attaining the age of 25, that is a properly valid bequest, and it will not vest or become payable until B. does attain that age. As far as I can judge without seeing a copy of the will, the executors can have no power to pay over the bequest until the legatee attains the age prescribed. The querist is, I think, quite mistaken in his information and his view of the matter. Although 21 years is often usual, a testator is quite at liberty to say that a legacy shall not vest until the person to be benefited attains the age he names—25, or even 75. It may be that this testator thought B. would be better able to manage a large fortune if he had four years' more experience.

(56726.)—Claim to Property.—I should advise this querist to consult the London solicitors having charge of the case; but without knowing more of the matter and seeing some papers, I cannot possibly help him further.

(56728.)—Agent—Default.—An agent can never be prosecuted for embezzlement, which applies only to clerks or servants. But sometimes an agent may be proceeded against as a fraudulent trustee. In this case, however, I do not think the querist has any other than the civil remedy of an action against his collector for money received on his account.

[56736.]—Partnership Agreement—Sta
If this agreement is not a deed—i.e., is not





seal, it only requires a 6d. stamp. If it is under seal, then it requires a 2s. stamp as a deed. If there are two copies, one would need a 10s. stamp, and the other only 5s., as a duplicate, if stamped at the same time. There is no *ad valorem* duty in question, and the 2s. 6d. stamp is wrong either way. The amount of capital has nothing to do with the point. **Fred. Wetherfield**, Solicitor.

2, Gresham-buildings, Guildhall, London.

## LOOPED FIGURES BY GEARING.

[24387.]—IN Vol. XXXV. our old friend "O. J. L." gave us some idea of what might be done by simple apparatus upon an ordinary lathe in his articles on "Looped Figures by Gearing." These suggestions led me to make certain small additions to my lathe, by means of which I was enabled to utilise the change wheels to rock a small ornamental slide-rest, and so produce various curves, some of which you printed on page 300 of Vol. XXXIX. Our friend's welcome reappearance in print reminds me that I have two more blocks which illustrate some further powers of the apparatus, some of which were quite unsuspected when the apparatus was made.

If you are good enough to print the blocks I now send, our friends will see some further illustrations of the rose-engine movement in one of them, and in the other they will see that by slightly altering the disposition of the parts, I have been enabled to produce cycloidal and trochoidal curves similar to those produced by the cycloidal chuck or by the epicycloidal cutting-frame. In all these patterns only the cast change-wheels of an ordinary Milne's slide-lathe were used. I may say that Mr. Milne has the few patterns required for the apparatus, with liberty to cast from them, and very good castings he sent me. Cut change-wheels would, of course, do better.

**F. A. M.**

## LATHE WITH VERTICAL SLIDE.

[24388.]—I NOW send you a cutting from the *American Machinist* of March 7th, describing a beautiful little lathe arranged with the vertical slide for milling, which I have so often advocated. The lathe is only 3½in. centres; but it is expensive, and it appears to be a kind of large watch lathe. It looks strong and (shall I say?) more English than most American work. I expect that before long an engineer's lathe will be considered incomplete without a vertical slide.

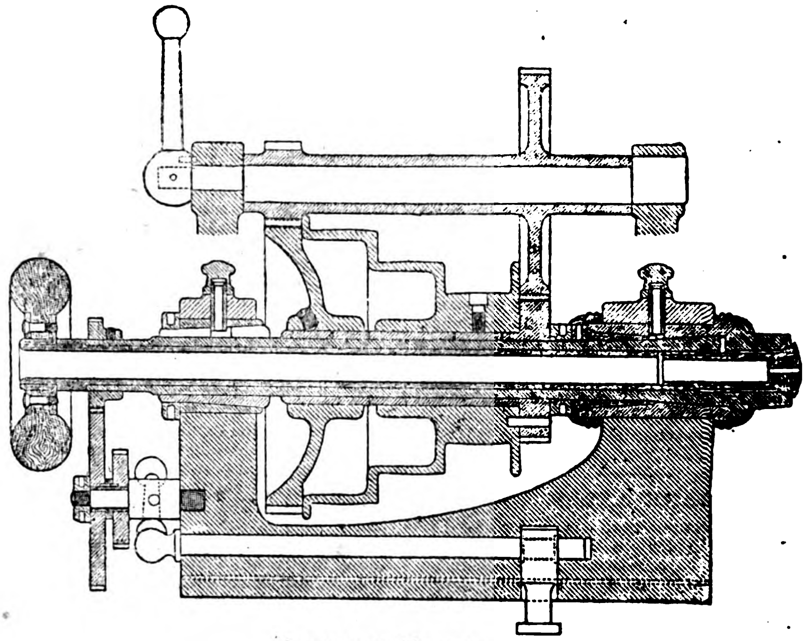
I have seen one of H. Walz's lathes, and consider the work very good and cheap; the method of raising guide-nut and releasing traversing mandrel by one movement of a handle is very convenient.

**F. A. M.**

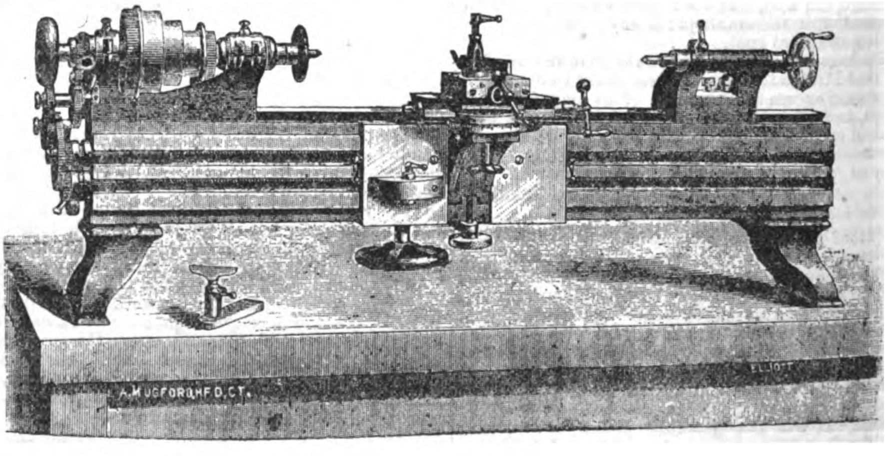
### SMALL UNIVERSAL ENGINE LATHE.

From the engravings which we present it will be seen that in the design of this lathe a radical departure has been made from the stereotyped plan of making small engine lathes—copies in miniature of larger ones. The construction is such that it will swing in line with the cutting tool as ordinarily used, a diameter about equal to what will be swung over the carriage of a commonly-constructed lathe of twice its nominal capacity.

As will be seen, the carriage may be run the entire length of the bed without coming in contact with either the head or tail-stock. The carriage is provided with a compound rest, which can be set at any angle, and which has direct vertical adjustment of 2in. Both the cross and angular feed screws of the compound rest are provided with micrometer heads reading to thousandths of an inch, the zero marks of which are adjustable to any fixed position of the slides, so that in many cases the micrometer arrangement may be used for sizing work instead of calipers or gauges, and at a good deal of saving in time. A T rest is furnished with the lathe, which is used in place of the compound rest when hand-tool work is being done.



SECTION OF HEADSTOCK.



The carriage is provided with every requisite adjustment for temporarily converting the lathe into a milling machine. If desired, a small milling machine vice is furnished, which can be screwed to the upper slide of the compound rest.

The lathe is provided with two leading screws, which are always ready for use, and are so situated as to be entirely protected from chips and dirt. One of these is a "precision screw," and is intended for use only for cutting fine and accurate screws. Both screws are geared alike, and will cut from 4 to 160 threads per inch, and from 8 to 80 per centimetre. The change gears are placed upon the stud and swinging arm instead of on the stud and screw, as is commonly done. When metric threads are to be cut, it is only necessary to substitute two translating gears—one on the screw and the other on the swinging arm—for those used for ordinary threads.

The lower part of the tail-stock is clamped to the bed by means of a cam; the upper part has a gibbed slide and clamp to set over for long tapers.

The lathe swings 7in. over bed and carriage, and is made with various lengths of bed from 42in. up. The hole through spindle is $\frac{6}{10}$in; largest hole through spring chuck, $\frac{4}{10}$in.

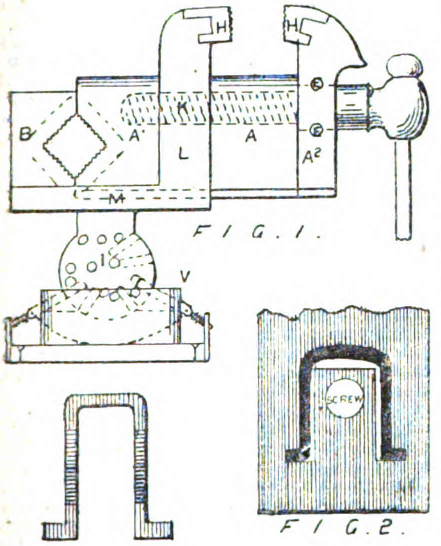
Larger spindles and chucks are made if desired. As will be seen from an inspection of sectional view, the spindle may be removed and another one substituted, or the boxes be replaced with others, without disturbing the running parts. In the sectional view the back gear is, for convenience, shown above the spindle, instead of in its actual position.

The workmanship on these lathes is excellent. The spindles and bearings are hardened and ground, and nothing but scrapers used in fitting sliding parts.

The Balloon Manufacturing Company, Hartford, Conn., are the manufacturers.

### COMBINED BENCH, PARALLEL VICE, AND TUBE VICE.

[24389.]—THINKING it would be of interest to your readers, I take the liberty of inclosing herewith a rough and rather inaccurate sketch of a combined bench, parallel vice, and tube vice, with special adjustment, recently patented by myself. If any of your readers like to make one for their own use they may. It will be seen by the globe I (which should be proportionately larger), that adjustment may be made to almost any angle and position, the holes bored in the globe fitting a ½in. steel rod, marked J. The teeth of the two vices and the screw are of steel, the other parts are of malleable iron. The screw K fits jaw L (Fig. 1), and is protected by cover A, which is also a dog of tube vice. L M and B are in one piece. A, $A^1$ and $A^2$ are in one piece also. Screw is fitted to *a* by means of groove and pins E. $A^1$ is the double jaw of tube vice (Fig. 3). Next week in the Sale Column I will advertise castings for this vice, and also the article complete. W. Bundy.



---

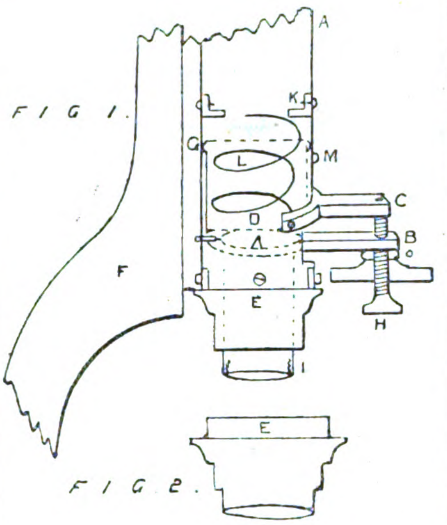
**Test for Copper and Lead in Wine.**—A new method for testing the freedom of wines from cupric and plumbic salts has been described by H. Hager in the *Analyst*. The wine is mixed with half its volume of a clear solution of caustic soda, which may contain carbonate. If the liquid remain clear after boiling, neither copper nor lead is present. A turbidity with colouration points to the presence of copper. About six cub. cent. of this solution are poured into a test tube, a piece of tinfoil introduced, and the whole heated for half an hour on the water bath. If lead and copper be absent, the foil remains perfectly bright; whereas if in the presence of a trace of one of these metals it becomes dull and grey for lead, and brown or brown-black for copper. This reaction may be applied to all cases when other metals are not present, and the solution remains clear after the addition of alkali.

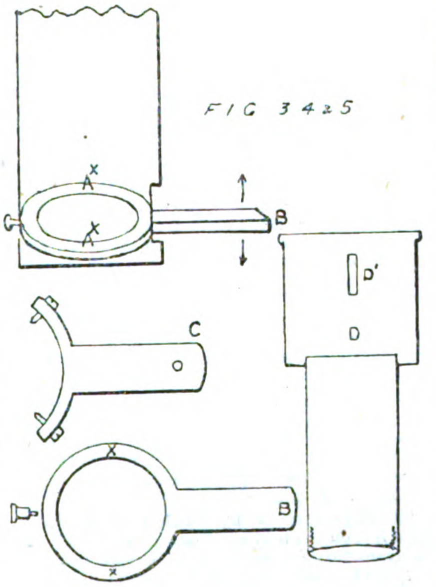
# REPLIES TO QUERIES.

◆

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[55819.] – **Microscope Fine Adjustment (U.Q.)**—"Sempervivo" will find this the form of adjustment he requires. It looks rather intricate; but a careful look at it will make all clear when the principle is seen. It can be made so that the milled head can be on the right, left, or middle. Fig. 1 is a sectional view, Fig. 2, 3, 4, and 5 the several parts. The dotted lines show the inside tube. A screw of about 60 threads to the inch should be used for the adjusting screw. All the castings can be supplied if "Sempervivo" does not want to make the patterns at the microscope maker's. I mean the actual makers, not the shop-tician. Shall be pleased to explain any part that is not clear.





A, body of microscope; B, lever for lifting objective tube; C, right angle piece for holding screw H; D, cylinder fitting body and lower casting *d* at I; E, casting for lower fitting; F, crane arm of microscope; G, solid brass block soldered to body; I, tube screwed to universal size; K, diaphragm to resist spiral spring L; D′, small slot to fit screw *m*; H, milled head; O, loose collar clearing screw; P has a tube soldered into the castings as shown. The sketches are as near actual size as possible, with the exception of the diameter of the tubes. $\updownarrow$ B indicates a play of ⅛in. up and down.—MENISCUS.

[56257.]–**Telescope Stand.**—I should advise "Omega" to procure a piece of scaffold pole 6in. or more in diameter, and not less than 9ft. long. (I presume that he has a garden, else, I should think that he would not want a cheap firm stand for his telescope). Dig a hole 3ft. deep and insert one end of pole in, hammer the earth all round the pole every few shovelfuls that are thrown in, until the hole is filled. If pole is not perpendicular give it a strong pull the way you want, and then pound away at the earth on same side to which it leaned. After a few such operations the pole will be firm enough for a telescope of double your aperture, especially after there have been a few showers of rain and the ground has got well set. Get a proper vertical and horizontal motion from an optician's. You will be best suited with one like those used with the claw table stands, and have it fastened to a piece of gas-pipe about 1ft. long. Now "let" a hole into the top of your pole in the garden that will hold the gaspipe in a horizontal position, half the gaspipe must project above the hole in the pole. Now procure sufficient lead that will make a cap for the top of pole, let it be concave at the top, and (of course, you will have it to mould); underneath let it have a groove that will fit the half of gaspipe which protrudes above the groove in the pole. Two holes must also be cast in the lead, or bored afterwards, directly opposite each other, and opposite the centre of the groove in the lead. These holes are for thumb-screws to screw the lead cap firmly on the top of the pole and to hold the gas-pipe tight. The thumb-screws will not be above 4d. each. Lead, the heavier and better, which should not be more than 7d. (I am reckoning at the rate of 1d. per lb.); gas-pipe not more than 6d.; scaffold pole, 9ft. long, not more than 1s. 6d. The vertical and horizontal motion to be screwed to your telescope I cannot speak definitely about; but that should not exceed 7s. 6d., so far as I am a judge of workmanship. I have a 3in. refractor, which I place upon a similarly constructed stand to what I have given here, and it has answered my purpose so far. For a cheap, firm stand it should suit "Omega."—D. BOOTH.

[56332.] – **Optical.**—I am sorry I did not see "Glatton's" reply before. The difficulty of the question is due to the thickness of the glass. Neglecting this, the result is easy to find. To find the mean position of $b$ for values of $\phi$ between 0° and 45°, we have, neglecting the thickness of the glass, $\sin. \delta = \mu \sin. \phi$, ∴ if $\phi = 45°$, $\theta = \sin.^{-1}\left(\frac{\mu}{\sqrt{2}}\right)$. Putting $\mu = \frac{3}{4}$ for rays passing from water into air we get $\theta = 32° 1'$. Also in this case, $D b = D P = B D \tan. \theta = B D \times \cdot 62528$, ∴ $B b = B D (1 - \cdot 62528) = B D \times \cdot 37472$, and when $\phi = 0°$, $\theta = 0°$ and $B b = 0$, ∴ mean value of $B b$ is $\cdot 18736 \times B D$ for values of $\phi$ between 0° and 45°. If the ray incident on D X is at an angle equal to the critical angle, $b$ will coincide with D, and for greater values of $\theta$ the ray will not emerge.—T. H. L.

[56475.]—**Nitrate of Iron.**—This query refers to what is pretty generally guarded as a trade secret. To save it getting into the U.Q. list Henry Holmes will find my address advertised this week.—W. JESSE LOVETT.

[56526.]—**Stained Floors.**—Scrape the parts and restain; or apply paint, and varnish that when dry.—DECO.

[56538.]–**Ink for Black-edged Note Paper.**—Use printers' ink, with extra strong, quick-drying varnish, and apply round the edge while the bulk of the sheet is protected by a stencil.—T. P.

[56542.]—**Staining Deal Floors.**—Try permanganate of potash.—DECO.

[56555.]—**Prof. Langley on the Solar Rays and the Atmosphere.**—Why should "R." think it "opposed to previous experience" that more heat should be obtained from the solar beam in a rare atmosphere than a dense one? Does not the sun brown the traveller's cheek on Mont Blanc, while in the valley they all shiver with cold?—S. P. T.

[56559.]—**A New Gum.**—Probably gum Kauri, but the "authority" is doubtful, as it is no more than a newspaper item.—C. K. T.

[56574.] — **Bearing Grease.**—Does "Inquisitor" want to sell the grease at the price named, or to make it at that cost?—ESSAR.

[56575.]—**Galvanometer.**—Is this query asked seriously? What is the use of a galvanometer if it is entirely concealed from view? Cannot querist manage to reflect the movements so that they can be read?—NUN. DOR.

[56579.]—**Pumps.**—This is a peculiar query, surely. What American pumps, and what principle does the querist suppose is employed different to all other deep-well pumps.—NUN. DOR.

[56604.]—**Differential Equations.**—It is true, as stated by "H. H.," that the differential equation in question occurs in the mathematical theory of electricity, although I should prefer to speak of the capacity of a conductor, or rather condenser, rather than the capacity of a circuit, and the current need not be alternating. In fact, to every such equation in the theory of heat there is a corresponding one in the theory of electricity. There are three or four quantities in each, which correspond to one another, as follows:—

| | |
|---|---|
| Heat. | Quantity of Electricity. |
| Temperature. | Potential. |
| Specific Heat. | Capacity. |
| Radiation. | Escape of Electricity. |

The differential equation is to be found in Clerk Maxwell's great treatise on "Electricity and Magnetism," who there states that it corresponds to the problem in the theory of heat I mentioned. —W. C. E.

[56620.]—**Steam Carriages.**—I thought the quotation from Reuleaux would clearly explain what was implied by the word "rails." It means some smooth, hard surface, such as the granite tramway laid down in the Commercial-road, E., leading to the West India Docks, or the asphalte in Cheapside. Flanged wheels are altogether beside the question, because it is a *sine qua non* with a steam carriage, that it shall be readily and perfectly steered. What "Progress" means is really a steam tramway. "Gwyllm Maesgwym" says my reply is "very one sided," but as he supplies the other side, it does not matter, only I should like to know where he finds anything believable about a steam carriage running 35 miles an hour. Expect it must be the same one that ascended old Highgate-hill (one in nine), and came down rather more quickly than it went up; but perhaps "G. M." will give chapter and verse for his statements. If I understand him, he traverses the dictum of Reuleaux, and "ventures to doubt it in toto." But what does he mean by "none were used by Gurney and Dance":—none what? He seems to have forgotten that Trevithick was a quarter of a century in advance of them, and that there were at least a dozen others equally as successful, and one (Hancock) certainly more successful. It is true that for a time heavy tolls were levied on Gurney's and on Dance's carriages, and the road was covered occasionally with a coat of soft gravel; but, so far from the success of their carriages being "indubitable," they failed like all the others, because of the enormous cost of repairs. Heaton Brothers, of Birmingham, did as much as anybody (with the exception of Hancock) to make steam carriages successful; but, after spending upwards of £2,000, they had the courage to acknowledge that to obtain an average speed of ten miles an hour the expenditure would exceed the receipts. The *Birmingham Journal* for April 12, 1834, was "authorised to state" that the experiments had not proved satisfactory, and that a meeting of shareholders would shortly be called. So far as I can find, neither Gurney nor Dance ever published a balance-sheet, or explained how much they had spent in repairs. I am much afraid that our friend "G. M." has relied upon Dr. Lardner's statements, or upon some work having the same origin.—Nun. Dob.

[56620.] — **Steam Carriages.** — With the Editor's permission, I shall be glad to enlist the attention of Mr. A. H. Bateman, whose remarks in No. 1,055, p. 329, of the "E.M." for 12th June, point him out as one suited to the production of a tricycle with accessory power beyond mere pedalling. I fancy the "motor tricycle," patented by Sir Thos. Parkyns, aimed at too much for attainment in the present state of motive power; and, as indicated by Mr. Bateman, had the steam power been sufficient to drive the machine up hills, it would have been positively dangerous on the level from the excessive speed possible. But pedalling on a level hard road is really a pleasure, and need not be fatiguing; on a falling gradient it may be very little or *nil*, to proceed at a pleasant speed; it is only the heavy adverse gradient, or slightly adverse gradient with a badly-surfaced road, that tries the rider; therefore, the desideratum is auxiliary power for perhaps one-third of the distance traversed. This would reduce the expenditure of extra motive power to one-third, consequently, save two-thirds of the fuel and water (if water) required. But that is not all the saving. In the "necessary qualifications" enumerated by Mr. Bateman, considerable extra weights for machinery and water are both contemplated; but query—are these necessary? In a former communication which you did me the honour of inserting, I offered some suggestions on this subject, in which the use of gas-engine power as an auxiliary to pedalling was advocated, provided such engine could be driven by the vapour of some hydrocarbon, and the usual "movements" of an engine simplified by shifting of the valves when required by the action of the pedals alone. This would reduce the "engine" to little more than a piston and piston rod, acting upon the driving-wheels' axle by a species of clutch action, to convert reciprocal into rotary movements; in fact, by making use of all the existing parts of an Omnicycle (except the hill-climbing gear, which might be dispensed with). The piston should be capable of being thrown in and out of gear readily as required. Of course, I am not able to suggest all the details; it requires somebody familiar with engines and engineering work to do that to best advantage; but in this direction I feel convinced that the additional weight required need not be serious.—Gamma Sigma.

[56650.]—**Lead-burning.**—Mr. Davies does not understand why I should try to put him right when he says the vitriol sold by druggists will not do for lead-burning. I say it will, and does every day, answer well. Mr. Davies keeps harping about his book. I have never seen his book, did not know there was a book, and he should remember that there are thousands of readers of your good publication who cannot buy all the books that are published, and hundreds of your readers who have not seen either his book or your back numbers, nor have the chance of seeing them. No doubt Mr. D. is very clever and kind, and I hope he has reaped his reward by the sale of his book. He asks what I would have him think when I speak of using clean zinc, free from paint and wire? Well, I would say that any lead burners, except mere learners on a bench or in a plumbing shop, would know that there is plenty of painted zinc with wire worked in it in the shape of ventilators and watering-cans that are often bought for lead-burners to work up, and I advised "Young Beginner" to shun the dirty stuff until he is more practised; as to throwing the dirty gas away, as Mr. Davies makes me say, I said nothing of the sort. I advised "Young Beginner" to make nothing but clean gas, and, by the way, how does Mr. D. make out that the gas is dirtier the first half-hour than after? This is contrary. Will any kind reader of our valuable magazine please to inform me how to have soap free enough for domestic use from lyes. I manage it now by finishing on common salt brine; but as this adds to the time and the expense, I am anxious to go the shortest way to work, as I am convinced there is a readier way than having this extra process or change of salt brine.—Henry Holmes.

[56673.] — **Mechanics.**—Thanking the correspondents who have taken so much pains to clear up my difficulty, and "M. R. C. S.," &c., for most interesting suggestions on the forming of four triangles by four straight lines, my difficulties as to the question in mechanics still remain, and which I will endeavour to express more clearly. I have not done much in solid geometry; but I was certainly under the impression that taking any four-sided pyramid it can have only one sphere described around it; therefore when Todhunter wrote "one of the described spheres," I cannot understand what he means. "Hemisus" says if all the forces are like, the centre of parallel force is at the centre of the inscribed sphere: this I reasoned out myself; but he says, if I understand, that, if unlike, the centre is at the centre of a described sphere. Now, suppose we have a tetrahedron, A B C D, and suppose force at A unlike the other forces, then it would seem to me that the centre of parallel forces ought to fall beyond the base opposite to A at a distance, if $p$ be straight line joining A to centre of base, equal to $\frac{1}{2} p$; now the centre of the described sphere must fall on $p$, as I see. Thanking "Hemisus" for his attempt, could he or someone else clear these further matters up?—J. C.

[56676.]—**Hardening Jaws for Chucks.**—I am obliged to Mr. Bundy for the information he gives, and for his kind offer to do the work for me. Having made the jaws, however, I am desirous of finishing them. Will Mr. Bundy say what amount of potash should be used in a given quantity of water, and what the temperature of the water should be; also whether the jaws should remain any length of time in the water.—Alfred West, Bridlington Quay.

[56679.]—**Supported Beam.**—In the original question, page 268, it is evident that "no tendency to break" refers to horizontal, not to vertical or shearing, strains. "Bacchus" is not quite correct, page 329, for there is no shearing at the centre of the beam.—J. S. C.

[56682.]—**Struck by Lightning.**—The "old scale left on the bottom of one of the feet" in this distressing case seems to indicate something of the nature of induration (less in degree) in the other parts of the body affected by the lightning stroke. In such case it would seem to me that applications tending to soften rather than to harden the flesh are indicated for relief, if not for permanent cure—as warm bathing. I am the more inclined to write thus on learning that the pains are acute when storms come on. Such pains are often ascribed erroneously to rheumatism, when they arise, I think, from atmospheric action on parts previously affected by rheumatism, or by other causes permanent, or leaving permanent effects, as in this case. It is quite certain that disturbances of atmospheric pressure, which storms indicate, are followed by re-arrangement through the bodily system, as well as externally. The air thus entering from without or escaping from within the body encounters resistance in hardened parts, and would make itself felt in parts left in irritable condition by previous disease. I have again and again on such occasions acted on the conviction in my own case that such pains are not rheumatic, and have been right. I advised a poor woman a short time ago to soften her feet by soaking in warm water, having this cause of suffering in my mind. I forgot the circumstance when I saw her a few days after; but she had not, the relief had so speedily and surely followed. I am not a medical man, but an observer only. I am careful, however, to keep back such statements as the above until conjecture has been followed by facts which recall it in a convincing manner again and again. Permanent cure may not, perhaps, be expected in such a case; but while I would recommend careful study of the whole of that passage in Job xxxiii. 14-30, I am strongly reminded by the 25th verse how much the habits of our life tend to induce premature old age, than to prolong or enable us to recover the freshness of youth. Everything tending to promote a healthy circulation of the blood will tend to soften and restore the flesh to a healthy state, such as moderation in eating and drinking, cleanliness, promoting free perspiration and exercise in whatever form it can be best taken. It is a case, I think, in which medicine may be of some little use, but wholly below such arrangements for healthy living as the fear of God and good sense teach.—J. M. Taylor.

[56743.]—**L. and N.W. Railway.**—Simple engines are at present the most popular with the drivers, owing to the scarcity of compounds, there being only about 40 in existence. Possibly it depends in a great measure upon the work which the engines have to do. The home of the engine Cornwall is at present at Whitchurch, and invariably runs local trains:—Whitchurch to Crewe, Crewe to Chester, Crewe to Stafford, and is this week running 5.20 p.m. train from Manchester to Crewe viâ Stockport.—Wild Rushes.

[56744.]—**Softening Water.**—I have seen a "Water Purifier" made by Gray and Sons, of Leadenhall-street, and although not a chemist, I managed to get water from 20cc. down to 2cc., Wanklin's soap test. I have been told that this apparatus is supplied with a set of nozzles properly calculated to regulate the proportion of the water and reagent, and thereby dispensing with a chemist. I believe this is one of the principal features. These nozzles could be altered to give any result, if necessary, but will probably be at their best when supplied. The apparatus is something like a coarse filter, but has the peculiarity of cleansing itself automatically. I think Wanklin's soap test is the easiest to work with, and cheaper than Clark's, and should be measured by an ordinary burette.—Kcalbred Naxela.

[56744.]—**Softening Water.**—An apparatus for this purpose is described in the *Journal* of the Society of Chemical Industry for May last. The patent number is 6,213; April 10, 1884. The apparatus is to be employed for the purpose of mixing lime-water or other liquid or liquids for use in the said process, or for mixing such liquids with lime or other solid matters. A hollow standard, capable of revolution on its own axis, and provided near its bottom with a hollow, perforated arm standing out at right angles, is placed in a tank, preferably near the floor, so that the apparatus may be immersed in the materials to be acted upon. At the top of the standard is an arrangement by means of which a stream of water can be injected under pressure, together with a quantity of air drawn in through apertures. The air and water pass down the hollow standard and along the arm until they reach the perforations through which they escape, causing a more or less violent agitation of the liquid by which the arm may be surrounded. The apparatus may be placed in the centre of a tank, or two or more of them may be placed in one tank, motion being given to them by suitable contrivances. In place of a stream of water under pressure, air may be forced from a pipe through the hollow standard. I believe there is a firm in London whose sole business is the working of the "Porter-Clark process"; no doubt they would advise "J. T. C." The best test of the hardness of water is to estimate its soap-destroying power. This is done by adding to it a "standard" solution of soap (i.e., a solution of known strength), and noting the quantity required before a lather is produced on shaking. "J. T. C." should ascertain, once for all, the hardness of his water. There would be a certain definite proportion of lime necessary, and corresponding to this degree of hardness, and this quantity would be kept to without alteration.—Chromio.

[56746.]—**A Disagreeable Noise.** — Great benefit will be derived by putting the anvil on a bed of indiarubber, say, 4in. or 5in. thick, let in the ground, taking care to prevent the hot scales getting near the indiarubber. If this does not suit your purpose, then persuade the lady to remove.—Wild Rushes.

[56746.] — **Disagreeable Noise.** — Get four pieces of cork about 4in. square, as thick as you can. Make them a little hollow, so that the surface will bear on each corner, and a groove on the other surface for the wheels, if required; or try indiarubber. Be sure and keep the bed from touching the walls.—Alexander.

[56770.]—**Putty.**—I have made it two or three times with the same materials as you used, and had no fault whatever to find with it. Reduce the whiting to powder, mix with oil, work well, and there is no fear the putty will be right. The rabbet or check for holding the glass should be primed before putting the glass in; it makes the putty stick.—David Stephen.

[56780.]—**Camping Stoves.**—I always use methylated-spirit stoves, as I consider they are best, although many of the oil stoves made are good. If you sleep on board your boat, you will require an "anchor lamp"—a lamp showing a clear white light all round—hung from the forestay or from a line made fast from the top of the mast to the bows. If you sleep in a tent, this lamp could be hung from the roof without danger of setting the tent on fire, as they are comparatively cool, burning sweet oil, and having no interior funnel, and for the same reason a similar lamp would do for the cabin. These lamps vary in price from 3s. to 10s., according to material and workmanship, and should only be purchased from a ship chandler, as similar lamps are made by tinsmiths, which are so easily blown out that they are worse than useless. —James M'Cash Govan.

[56783.]—**Problem.**—I do not think the answers given to "Trophy's" question are correct. The first supposes a mistake in the question, and, therefore furnishes an incorrect answer. The second makes $x = 800$, $y = 80$, $z = 160$ gallons. Now, if $M$ = time A. take to empty hold, then A. pumps $x + My$ in doing so, $My$ = amount of water brought in by leak. A. will pump $\frac{x + My}{M}$ gallons per hour = $z$ in answer. A. in 3¾ hours will pump $\frac{x + My}{M} \times \frac{15}{4}$ gallons, $\frac{15}{4}$ hours being time taken to empty hold, both working together. Now this, according to question, is 10 gallons more than A. did pump out. Now, by question, A. worked for 13⅓ − M hours, and in that time would pump out $\left(\frac{40}{3} - M\right)\frac{x + My}{M}$ gallons; and this quantity is stated to be less by 10 gallons than the previous; thus—

$$\left(\frac{40}{3} - M\right)\frac{x + My}{M} = \frac{x + My}{M} \times \frac{15}{4} - 10.$$

Putting—

$$\frac{x + My}{M} = z = 160, M = 10, x = 800, y = 80,$$

we get 160 = 177, which is clearly wrong. The values I get are $x = 120$, $y = 12$, $M = 10$, $z = 24$, which seem to me to satisfy all equations obtained from the question.—J. C.

[56788.]—**Agglomerate Battery.**—I have been troubled in the same way, and found the cause due to the contact between the lead cap and the carbon being faulty. I found mine out by testing with a piece of copper wire held against the carbon instead of connecting to lead cap. I put mine right by melting off old caps and casting on new ones.—Egbokg.

[56795.]—**To Mr. Wimshurst.**—To answer the questions of "W. B." would take more space in your columns than would be reasonable. Moreover, even then, owing to the absence of knowledge, the subject would be left quite open; but if "W. B." turns back your pages to January, 1883, he will find your descriptions of the machine, and have as good a working hypothesis as perhaps can be obtained. Unless the two sectors in line across the plates be brought into perfect metallic contact with each other by means of the brushes and rods, the machine will not obtain excitement, and when excited, very little resistance can be put into this circuit between the brushes without losing the excitement; therefore, I think he would not obtain either the spark or charge of any great value by connecting these rods to an insulated prime conductor. My system of using the current from the brushes is to add a length of vulcanite to form part length of the neutralising rod.—James Wimshurst, 4, The Grove, Clapham-common.

[56796.]—**Boiler.**—To "Invicta."—Your boiler, 9in. square and 20in. high, would need before using it for steam, to be fitted with stays. I should fit these in by drilling holes, so that three stays were fitted. The holes must, of course, be arranged vertically, so that the stays pass one another. I should make them of ½in. round iron with the ends screwed; by passing them through the holes nuts can be screwed on the ends with cement or a lead washer under each nut to make the joint. When these stays are in so that the flat sides are relieved of pressure, a stay should be fitted to the boiler to stay the ends. This would be best done by two stays, as they would miss the other cross stays. When you have all secure you might, supposing the plates are good and not wasted by the welding, be safely able to run at, say, 25lb. pressure. I prefer, with a welded generator and of square section, to be well on the safe side. If all be perfect, no doubt a very much higher pressure would be safe. But, unless I saw and satisfied myself as to the soundness of all parts, I would prefer to be well within the limit of safety. I should fix such a boiler in a brick setting vertically, the fire being in front and carried round with a shell flue. Such a boiler would supply steam for an engine either 1¼in. bore by 3in. stroke, or 2in. bore and 4in. stroke. I should carry the water line up to 14in., thus leaving ample steam room. Safety-valve should be to allow ample area, $\frac{13}{16}$in. in the clear bore, not the outside of valve: this would give a fraction over half a square inch. Let the joint or point of resistance be ¾in. from the centre of the valve. Length of lever from centre of point of resistance to end 5in. Let the weight be 2oz., and steam should blow off at 24lb., whilst the weight of lever and valve will at least increase the pressure another pound, thus giving 25lb. to blow at. —Invicta.

[56798.]—**Filter.**—Taking the fall into account, the flume will not give more than 40 gallons of water per minute—i.e., 960 gallons per diem (24 hours). The filter which I should say would suit "Backwoodsman's" purpose will be such a one as is used by waterworks companies, which is composed as follows:—18in. puddled clay, 5ft. of ordinary small stones, known as "metal," 3ft. of gravel, 2ft. of sand. In the clay is laid the exhaust troughs, covered with larger boulders, to keep the way clear. Such a filter will filter 500 gallons per 24 hours per square yard, and will cost about 15s. the square yard. If the above heights are too great, reduce the metal to 3ft. 6in., and gravel to 2ft. 6in. If this filter will not do, "Backwoodsman" might use charcoal filters, but they will be expensive.—Boolie.

[56806.]—**Foci of Lenses.**—The focus of all converging lenses, which are the bi-convex, plano-convex, and meniscus forms, can be found easily enough. Thus, by holding the lens you want to find the focus of in the light of the sun, and moving it to or from a sheet of white paper or a whitened wall, at a point a distinct and sharply-defined spot of light will be seen. The distance of the lens from the image thus formed is the focus. You may also employ a lamp or gas-jet, and from the image of it in the same way get the focus; but in that case the lamp or light should be not less than 20ft. away. Divergent or concave lenses are not so easily dealt with, as they do not bring the rays to a point or visible focus. One way is to ascertain exactly the size of the concave lens. Supposing it to be 1in. diam., then draw on a piece of paper a circle exactly 2in. diameter. Now pin the paper on a wall facing the lime, and hold the concave lens at such a distance from the paper that the circle of light passing through it just fills up the 2in. circle on the paper. The distance apart of the paper and the lens would be its focus. There are other ways of finding the focus, but I consider this as simple as any. A converging achromatic is dealt with in the same way as the simple magnifying lens, and the concave the same, the only difference being that the resultant focus is that of the combination, and not that of either of its components. The cement used for achromatic lenses is usually Canada balsam. One well-known telescope o.g. maker used to use a cement of equal parts of oil of cassia and either Canada balsam or castor oil.—Invicta.

[56807.]—**Buttons and Buttonholes.**—Would not some sort of a light spring clip do instead of the button-hole?—Cymro.

[56811.]—**Surface Condensers.**—To "Invicta" and Others.—Two forms, giving equally good results, are available for you to choose from. One is that of two tubes of the same length, but one, say, 1in. less in external diameter than the other; the smaller being placed inside the larger, and the annular space at each end closed, an annular condensing chamber is formed, which would be found exceedingly effective; the whole condenser being placed in a tank a little larger than itself. Or a core of tubing of sufficient length may be used in a similar tank. In either case the equivalent condensing surface of 30ft. of 1in. pipe per horse-power is sufficient. As to the volume of cold water, about one gallon of cold water per minute is needed for each horse-power, with a surface condenser and low-pressure steam, such as you mention. Air-pump may be of such dimensions that it is one-third the area of the steam cylinder, the stroke being that of the steam cylinder. For such low pressures I should allow 38 to 40 square inches to each horse-power on the piston.—Invicta.

[56812.]—**Terrestrial Telescope.**—You can easily get a new flint lens fitted, if the instrument is worth it, by sending the remaining lens, with the broken one, to any good optician's.—Invicta.

[56813.]—**Fracture of Water-Gauge Tube.** —The reason these ideas have entered the mind of the querist is probably owing to a heavy supper, which has produced a very vivid nightmare, and thus given the semblance of reality to a disordered imagination. I have often cleaned glass gauge-tubes in the way mentioned, and have sometimes even scraped them clean with a bent wire. I once worked a boiler with a wire up the tube to collect incrustation and prevent it lodging on the inner surface of the glass. My glasses wear out, but they never break.—Bacchus.

[56815.]—**Tank.**—I should prefer the outlet-pipe in the bottom to the siphon. Theoretically the siphon would not deliver the same volume of water per minute as the simple outlet. And beyond this a siphon quickly loses a part at least of its power of discharge. So that both in theory and practice a discharge-pipe on the bottom is preferable.—Invicta.

[56817.]—**To Mr. Wenham.**—The arrangement for equalising the wear of the guide screw adapted by Andrew Muir to his lathe, consisted of a flat bar attached at one end by a bolt to the slide or saddle, and at the other resting in a bearing from the outer end of the lathe-bed. This bar carried the usual form of handle and clip nut, which could be clamped and fixed on the bar in any part of its length. The object of this addition was to distribute the undue wear that would otherwise occur in one spot on the guide-screw, by constantly cutting short screws, such as taps. Of course, if very long screws were to be cut, requiring nearly the whole traverse, this arrangement would not be needed; and if in the way, could at once be taken off, and the primary clip-nut employed as usual. Both clip-nuts might be set in gear at the same time without interfering with each other; but I am not aware that this was ever practised.—F. H. Wenham.

[56818.]—**Spherical Aberration.**—Yes. The distance between the lenses produces an effect upon the spherical aberration which is even more conspicuous than that produced upon the colour. I have within the last week received from a very skilled artist what I believe, to be a fine telescope of 3½in. aperture, constructed with the special view of correcting spherical aberration by adjustment of the distance between the lenses. I hope soon to be able to send, with our Editor's kind permission, some account of its construction and performance.—W. G. P.

[56819.]—**Pickle for Brass.**—"J. H. D." will find this method answer his purpose: First, wash the article in a solution of caustic soda and dry in hot sawdust—this will remove all grease; then dip for a few seconds in the following solution: 15 parts by weight of oil of vitriol, 15 parts of nitric acid, and 3 parts of common salt, which must be well dried in an oven; then mix all three together, and stir with a glass rod. Afterwards wash the article in hot water, and dry as before. This will produce a good dead colour, which can be brightened by scratching or burnishing.—Edward Antipessent.

[56820.]—**Commutator.**—A commutator is for reversing the current in the primary, which reverses the poles of the electro-magnet, which, in its turn, alters the direction of the secondary current. You need not expect 1in. spark: you should be quite content with ¼in. spark, if you get that. With a ½in. spark you will be able to light up a 12in. vacuum tube. It is for reversing the current when lighting up vacuum tubes that the commutator is necessary. Two one-quart bichromates is heaps—one would do.—C. L.

[56820.]—**Commutator.**—The commutator is an extremely useful addition to an intensity coil, although it cannot be regarded as one of its essential parts. For a coil the size of yours it would be better to have one, and I should advise accordingly. The commutator has two very important purposes: (1) To change the direction in which the current flows through the primary, and consequently changing the direction of the current in the secondary circuit also. Hence it acts as a current-reverser, and is very useful in many experiments. (2) It may not only be used as a reverser, but also as a current-suspender. Presuming it is made of a cylinder of ebonite or ivory, with springs pressing upon plates of brass on two opposite sides of the cylinder; if the cylinder be turned one quarter of a revolution, contact will be broken, as the springs will rest upon the ivory or ebonite between the two brass plates. This enables the arrangements for the secondary current to be made without the chance of receiving an unpleasant shock. If the insulation is good, the manner in which you have built your coil should suffice; but do not be disappointed if a 1in. spark is not obtained. A condenser will be necessary, its size being in proportion to the battery-power you propose to employ, and best ascertained by experiment.—Bobadil.

[56825.]—**Mechanical Question.**—I think that "Student" has made a slip of the pen, and that in his given case "similarly supported" should be "horizontally supported." This change would make the case be consistent with the strength of fir as given in Molesworth's Pocket Book. Of course, the beam when supported with an inclination of 60°, will carry twice the weight that it would do when horizontal. The required depth of the first-mentioned beam is 3·534in.—Dubliniensis.

[56825.]—**Mechanical Question.**—Resolve the weight into two components, parallel and at right angles to the beam. Neglecting the former for the latter we have—

$$W \cos. \theta = 2{,}240 \cos. 60^\circ = 1{,}120\text{lb.}$$

Let $x$ = required depth, bearing in mind that the strength of a beam varies inversely as the length, directly as the breadth, and as one depth squared we have the proportion—

$$1 : \frac{2x^2}{10} : : 450 : 1120$$

from which—

$$x = \frac{\sqrt{112}}{3} = 3\ 63\text{in.}$$

This is not providing a factor of safety.—David Stephen.

[56826.]—**Loss of Power.**—If the ½ ton mass be moved to and fro by a bar worked by a crank connected with a sufficient fly-wheel, the energy expended in communicating kinetic energy to the mass will be exactly repaid during the retardation of the mass; so that we have to think only of the work done against friction. In the present case the coefficient of friction is about ·032; so that the resisting force of the friction is about ½ ton × ·032, or 35·84lb.; and the work done per minute is 573·4 foot-pounds. If the mass be moved to and fro without a fly-wheel, or some equivalent appliances, the question cannot be answered without knowing the velocity imparted to the mass at every stroke.—Dubliniensis.

[56827.]—**Loss of Power.**—The coefficient of friction may be taken as $\frac{1}{10}$. The distance weight moves per min. is 16ft., therefore the work lost in overcoming friction $= \frac{2{,}240 \times 16}{2 \times 10} = 1{,}792$ ft.-lb. per min. The work done on a body of $w$ lb. to give it a velocity of $v$ ft. per sec. is given by the formula $\frac{w v^2}{2g}$. This is also the measure of work done against the body in order to stop it. Taking the greatest velocity double its average velocity, we shall have $v = \frac{16 \times 2}{60} = \frac{32}{60}$, and the work done in the eight starts and stoppages will be

$$\frac{1{,}120 \times \left(\frac{32}{60}\right)^2 \times 8}{2 \times 32} = 39\ 82 \text{ ft.-lb. per min.}$$

—David Stephen.

[56832.]—**Steam.**—To get the number of cubic inches in the cylinder, multiply the diameter by $\pi$ ($\pi = 3{\cdot}14159$), and multiply this (the area of the cylinder cover) by 72in. (stroke). This will give the total number of cubic inches in the cylinder. Steam is cut off at ⅕ of stroke, ∴ only ⅕ cylinder full is used at each stroke, so that the capacity of cylinder × ⅕ = amount of cubic inches of steam used per stroke.

Diam. = 32. Area = 32 × 3 14159 = 106·81406 sq. in.
106·81406 × 72 = 7,690·61232 cubic in. in cylinder.

$$\frac{7{,}690{\cdot}61232}{5} = 1{,}538{\cdot}122$$ cubic in. of steam per stroke used. To find the amount of condensation water required by one of the old-fashioned condensers, multiply temperature of steam by ·019, when the product will be the number of gallons of water required per minute per h.p. Temperature of steam at 35lb. = 280°; 280 × ·019 = 5·12 gals. per min. per h.p.—Boolie.

# UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

# QUERIES.

[56831.]—**Removing Zinc from Tin Solder.**—I have some tin solder which contains some zinc. Would any reader oblige by giving a method for the removal of zinc in it?—Penwith.

[56832.]—**Engine Query.**—I have a pair of valve laths, but I cannot tell the whereabouts of the piston by their use. Of course I know there are machines for such use, but I should like a rule to work on for marking the laths without a machine.—Num Skull.

[56833.]—**Horizontal Engine.**—Could any of our readers kindly assist me with a horizontal engine. I have cylinder 1½in. bore, 3in. stroke, also a flywheel 6in. diameter—or say where I could see a detailed drawing? and oblige—Alexander.

[56834.]—**Sundials.**—Will some correspondent refer me to a work on the graduation of sundials?—Rosicrucian.

[56835.]—**Copying Drawings.**—Some time ago I had a formula given me for copying drawings, composed of ammonio-citrate of iron 15 drachms, red prussiate of potash 10 drachms, distilled water 16oz. I have mixed up the solution and painted it on a sheet of paper, and have both put the drawing on top and underneath the paper under glass, but cannot arrive at any result. Could any of "ours" enlighten me as to how to go to work by giving full particulars?—W. R. A.

[56836.]—**Telescope.**—"E. R. H." wants to utilise a 5in. achromatic lens, for a direct-vision astronomical telescope. What length of tube, and what kind of eyepiece would be needed?—E. R. H.

[56837.]—**Drill Chuck.**—Will "T. F." please to inform me if the Little Giant drill chuck (he recommended a fortnight ago) will hold twist drills down to ⅛in.?—T. H. and S.

[56838.]—**Telescope.**—I have a tourist telescope, achromatic o.g., 2in. dia., 24in. focus, with which I want to use a stronger eyepiece, without doing away with its present one. How can the right distance between the two sets of lenses be found? And would it be well to shorten the tube to that distance, and have a band inside with thread, to restore the tube to its present length?—Eyepiece.

[56839.]—**Automatic Steering Gear.**—I wish to fit an automatic steering gear to a 2½ft. model yacht, to make the rudder port and starboard, once every minute. I suppose it will have to be done with spring and train of wheels. Could anyone oblige with description and drawing of same?—Tiller.

[56840.]—**Rubber Stamps.**—I have a machine and appliances for rubber-stamp making, and can make any name when the impression is taken from type. I am anxious to make signature stamps. Will some fellow-reader kindly say how I must proceed?—Autograph.

[56841.]—**Accumulator.**—Will some kind correspondent give the rule to find the weight required on column of water, the height of which is 36in. by 18in. dia., with a discharge tube, 1in. diameter, inside at bottom of accumulator, to give 50lb., 100lb., and 150lb. pressure per square inch? Also to find the power required to keep up the supply of water in accumulator, and how to find the required thickness of metal of cast-iron accumulators to stand the several pressures given?—One Anxious to Learn.

[56842.]—**Lathe Query.**—Will Dr. Edmunds or Mr. Hines please say of what material the laps are composed that are used for finishing screws in lathe as referred to in letters recently in the English Mechanic? As with a lead lap it is difficult to retain a sharp edge for getting in corners, I suppose it must be some kind of soft brass or bronze.—W. B. S.

[56843.]—**To Mr. Wetherfield.**—I have a little boy who is nearly old enough to be sent to school. Instead of sending him to school in this place (to learn slang expressions and impudence), I should be very glad if you would inform me whether I can legally keep the child at home and educate him myself until he is old enough to be sent to a proper school? I hold an appointment in the Civil Service, and have, therefore, previously passed a competitive examination held by the Civil Service Commissioners. I ought, therefore, to be able to set aside any question that might arise as to my ability to educate my child in elementary subjects.—Ecossais.

[56844.]—**Mathematical.**—If the centre of a circle be the pole, shew that the polar equation to the chord of) the circle which subtends an angle 2B at the centre is $r = c \cos. B. \sec (\theta - a)$ where $a$ is the angle between the initial line, and the straight line from the centre which bisects the chord. Deduce the polar equation to a straight line touching the circle at a given point.—Conic.

[56845.]—**Coil Springs.**—I should feel much obliged if any of your numerous readers could assist me by a description of the successful method, to enable me to manufacture springs, something like a large clock spring. I propose to employ steel 8in. wide, by 17 B.W.G. thick, and 28ft. long, and when it is coiled to say 9in. diameter. I want it on a 2in. diameter shaft, to take say 11 revolutions, and sustain a weight or traction of 300lb. I can have any temper or quality of steel from good reliable makers, but it is not possible to get anyone to undertake the manufacture, so that I am obliged to undertake the work myself.—Bouclier.

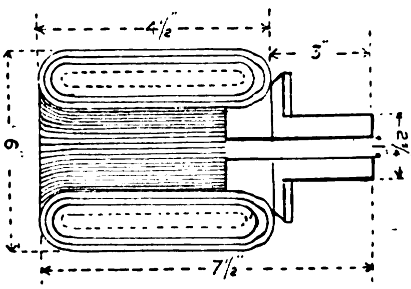
[56846.]—**Connecting Electric Bells.**—I have two electric bells with separate circuits, and I make the ringing of one complete the circuit of the other, so that the latter should ring until stopped. That is accomplished by means of an arm resting against hammer of first bell. The falling arm is insulated, but by its weight, the hammer of the bell on which it rests falls down, completing circuit of inner bell, without the outer one being rung. On the other hand, if the falling arm is made lighter, it will not press with sufficient power on falling, to make a perfect contact. If the falling arm is set too delicately, it will slip past the hammer (by reason of its weight, as explained): if more firmly set, it prevents the outer bell from ringing. Is there no other way of connecting these two bells? Should be very grateful for information as to methods of making the ringing of one bell start another.—Ignorant.

[56847.]—**To Mr. Lancaster or "Rob. Cru."**—I am about to make a telescope, and should like to know whether an achromatic object glass, 2½in. in diameter, with a 40in. focus, will be better than a ditto 2¾in., with a 50in. focus. Which would make the best telescope?—Focus.

[56848.]—**Grinding Pearl Barley.**—I have a mill for making pearl barley, and when working, a large quantity of very fine dust is flowing through the building, which is most disagreeable and unwholesome. There is a loft above this place, into which I think of driving the dust. Would any of your readers kindly help me?—X. X.

[56849.]—**Sewing Machine Motor.**—I have just made one of these, castings by Cuttriss and Co., of Leeds, style B1. The makers of castings say they are guaranteed to drive a small sewing machine. I use 6pt. Bichromate cells, and find armature starts off at a good speed, but very soon slackens until it stops. Without doing any work it will go on for a long time, but connecting it with sewing machine, it soon stops. If I disconnect the battery, and connect again in about five minutes, the motor works all right for another short period. Can any reader inform me where I am wrong? Is it in the winding, or battery? I should be pleased to forward it to be tried if any kind friend would take pity on a—Beginner.

[56850.]—**Dynamo.**—To Mr. Bottone.—Will you please help me in the following? I am making a dynamo with Gramme armature, and as my ring is finished, I want to know how to get the best effect. The dimensions of ring are as sketch. It has 672yds. of No. 16 B.W.G. wire, wound in 56 sections; and its resistance is 4·93 ohms approximately. Now, I want to know whether, with suitable F.M.'s, I could run 10 20c.p. lamps in parallel, with dynamo wound as series machine, or would it be better to run the arc light, and wind it as a shunt? My experience in this branch of electricity is rather limited, and I should feel obliged if you would give me any assistance you can, as to amount of wire, &c. I propose to use about 1 h.p.—Ignorant.



[56851.]—**Small Motor Castings.**—Having purchased a set of small motor castings, I find one F.M. to be a ¼lb. heavier than the other, the pattern being also different. Before finishing, I should like to know if the motor would be as good (other things being equal) as one where the F.M.'s are alike, *i.e.*, would one heavy and one light F.M. cause armature to rotate?—An "E.M."

[56852.]—**Quart Size Bunsen Cell.**—To "Sigma."—If "Sigma," or some other competent electrician, would answer me the following questions, I should be extremely obliged:—Note—fumes, trouble and expense of working, well known to inquirer, and expense no object. 1. To produce one arc light from the whole 50 cells, which would be the best way to arrange them, also what thickness of carbon rods in lamp? 2. Suppose two arc lights, what best way to arrange each 25 cells, and what size of carbon rods in lamp? 3. Using the whole 50 cells for incandescent lighting, about how many 20c.p. lamps will they render fully incandescent, also what will be the best way to arrange cells for this purpose? 4. What size of main leads? Distance from battery to lamps in each case, about 20yd.—Experimentalist.

[56853.]—**Writers' Cramp.**—I have been suffering from writers' cramp for many years, and have consulted many doctors, with no good results. No one in this country has found a complete cure for the disease. In the latter end of last year, a German (a Mr. Wolff by name) came over to this country, who professed to cure this disease. I went under his treatment, and improved a little, but on beginning to write constantly, I immediately became worse and now I can't write at all. I should like to know if any have been so cured by Mr. Wolff's treatment that they can write easily and well daily. I hope that any who have been perfectly restored themselves, or know of any that have been so, will kindly reply to this inquiry. —W. G. S.

[56854.]—**Valves in Compound Condensing Engines.**—May I ask some reader for an explanation of the action of the valves in compound condensing engines. It is a subject of much interest to many besides myself, and would be much simplified by sectional sketch.—Boolie.

[56855.]—**Inorganic Chemistry.**—Will some successful candidate advise me as to what are the best books for home study, in order to pass the Honours Inorganic Chemistry (S K.)? I cannot conveniently attend lectures, or I should prefer that. I have passed the two earlier stages.—Boolie.

[56856.]—**Engine Query.**—If 400 tons be raised 10ft. in six minutes by a steam engine, wherein the area of the piston is 400 square inches, the mean pressure of the steam on the piston is 25lb. on the square inch, the length of stroke is 4ft., and the number of double strokes made in a minute is fifteen, what proportion of the power applied to the piston is lost in the working of the machinery?—Goodeve.

[56857.]—**Diminished Power of Engine**—When the reversing lever of a locomotive is moved towards the central position, after being pulled over, the power of the engine is diminished. Why is this?—Goodeve.

[56858.]—**Horse Power of Engine.**—If the boiler of an engine gives out every minute 100 cubic feet of steam which propels the piston with an average pressure of 50lb. on the square inch, what is the h.p. of the engine?—Goodeve.

[56859.]—**Vertical Galvanometer.**—Culley says, "When testing, if no better instrument is at hand, use the ordinary vertical detector; but its sensitiveness is much increased if it is laid on its back." Twice lately I have been so placed, so put the instrument on its back with the N. end of the needle pointing north; but its readings are not to be relied on when so placed. The needle seems to move forward in a jolting fashion, and then suddenly remain fixed, for instance, unplugging 30 ohms did not move the needle back at all, whereas when upright, it moves over 9deg. It is an ordinary best quality detector, wound for high and low resistance, and is only a few weeks since new. Can anyone tell me why its movements, when horizontal, are so uncertain, and the best way to remedy same?—M. M. I. Sc. S.

[56860.]—**L. and N.W.R. Compound Locos.**—Will some of your correspondents, connected with the L. and N.W.R. tell me whether the high and low pressure cylinders of the compound loco., Marchioness of Stafford, in the Inventions Exhibition, are in any way coupled together so as to keep the low-pressure crank at right angles to one high-pressure crank and opposite the other? No coupling rod is shown in the two-page drawing in *Engineering*, May 1st.—Crumby.

[56861.]—**Eccentric on Crank Shaft.**—An eccentric is to be placed on a crank shaft at an angle of, say, 110deg. in advance of the crank. Would some reader describe the way in which they would proceed to mark off its position?—S. S. N.

[56862.]—**Scraping Metal Surfaces.**—Will some kind reader tell me the proper shape and method of using a scraper for trueing up and frosting metal surfaces, or can I get a book on the subject?—E. C. B.

[56863.]—**Flexible Material for Winding round Piston.**—Can any reader kindly inform me of any material, very flexible and strong, which will wind once round a piston 1·6in. diameter and pull out straight again as often as required? The pull upon the free end of this band is to communicate rotary motion to the piston. The width of the band not to exceed 1·6in. Something like the steel measuring tapes lately come into use should do, I think.—C. D. D.

[56864.]—**Safe Making.**—Wanted some practical hints on iron safe making, and a recipe for fireproofing mixture.—W. Bundy.

[56865.]—**Bolts and Nuts.**—Wanted information as to the making of bolts and nuts.—W. Bundy.

[56866.]—**Hand Drilling.**—Wanted hints to make a good easily made hand-drilling machine, double motion drill up to about ⅜in.—W. Bundy.

[56867.]—**Gas Engines.**—To "J. H" and others.—Supposing the gaseous charge was served by means of a cam once every revolution, would the suction only of the piston be sufficient to charge the cylinder with gas? Further, would an electric spark ignite the gas? Would a current of pure cold air be sufficient to cool the cylinder without the aid of water? If three ignitions were to take place on the outer stroke instead of one, would it not equalise the speed and power to a greater degree? What would be the heat of the cylinder of a gas-engine if the water supply were stopped, and if heat would be sufficient to vapourise paraffin oil? If a mixture ⅓rd paraffin vapour, ⅓rd coal gas, and ⅓rd steam, were introduced into cylinder in place of coal gas, would it give greater power at less expense? Further, is coal gas in a heated state more effective than when cold?—W. Bundy.

[56868.]—**To Chemists and Metallurgists.**—Will any of our chemical or metallurgical friends be kind enough to give some method for the estimation of cuprous oxide ($Cu_2O$) in metallic copper? I believe such estimations are occasionally performed in copper works and assay laboratories. So far as I have looked I can find no directions for such work in the books accessible to me. Perhaps our courteous friends Mr. Green or Mr. Allen or some other gentleman, will kindly notice this inquiry. Metallic copper contains, usually, arsenic and antimony and also traces of other elements. Supposing we take a weighed quantity of copper and estimate the above in it, to estimate the percentage of these volatile elements, could sufficient data be procured by roasting a weighed quantity of copper in a finely-divided condition to oxide ($CuO$), and taking into consideration the loss of weight ensuing from the absence of the arsenic and antimony, which would, I presume, escape on strong ignition of the copper. Is such a process workable?—Laudanum.

[56869.]—**Grey Acetate of Lime.**—Could any of your correspondents inform me how much grey acetate of lime could be made with the acid from a ton of wood such as black birch?—Marshall Reid.

[56870.]—**Potter's Kiln.**—To Mr. S. Arlidge.—Would Mr. A. kindly either publish or send me sketch, to scale, of kiln, and say about probable cost of building, and if it has proved a success, and also diameter of same? Also state if the kiln would be suitable for doing white or other glazing (bricks) in, and if it would be suitable for burning red brick? I do not quite understand if the kiln is a down or up draught, but I think it is the latter. How many ordinary bricks would it hold? Address published.—Thos. Plunkett.

[56871.]—**Whitewash.**—I want a good bright whitewash that will not rub off and will stand the weather. I have seen a very hard bright whitewash, but cannot get to know how it is done.—J. H. W.

[56872.]—**Coil**—A friend of mine has just completed an intensity coil for shocking purposes, but finds, from some cause or other, that it will not act. The primary consists of two layers of No. 16 c.c wire, and the secondary six layers of No. 28 c.c., each layer carefully paraffined and separated from the next by a sheet of paraffined blotting paper. The wire of both coils was found to be continuous when tested by a galvanometer. The battery power is two Daniell cells, each a pint capacity, which is powerful enough to work a contact breaker. All the connections are properly made. Perhaps some of "ours" may be able to offer some suggestions, for which I will be thankful.—Cymro.

[56873.]—**Terrestrial Eyepiece**—I have four lenses belonging to a pancratic terrestrial eyepiece, but do not know at what distances to place them apart nor where the diaphragms should be. Their foci are as follows: 1st lens (eye lens), 1⅜in.; 2nd lens, 2¼in.; 3rd lens, 2⅝in.; 4th lens 2¼in. The focus of o.g. is 38in., and aperture 2⅝in. Please say whether there is any rule dealing with pancratic eyepieces as there is with astronomical oculars, and how is the power calculated?—Cymro.

[56874.]—**Estimation of Magnesia.**—Will some of our friends kindly inform me what deduction, if any, should be made in estimating the weight of magnesia in, say, 100 parts of phosphate of magnesia obtained by precipitating magnesia from solution with phosphate of soda?—Chemical.

[56875.]—**Thymol.**—Can some chemical friend inform me if a solution of thymol can be made miscible with water? I have tried a solution in alcohol, but when mixed with cold water separation takes place, and the thymol rises to the surface.—Novice.

[56876.]—**Reflectors.**—Will any of "ours" kindly tell me the best plan for making the tube for the same, for a 9in. say? Would it be best to make it in lengths the width of a sheet of iron? I thought of making a cylinder of wood to bend it on. Any hints as regards the constructing of the barrel would oblige—Nigrum.

[56877.]—**Coil Winder.**—Will someone who has had experience with above kindly describe an efficient form of it as automatic as possible? Should description occupy too much space, will advertise address and pay all expenses?—W. G. F.

[56878.]—**Mineral Water.**—In the preparation of mineral waters, I use a quantity of citric acid, but a friend informs me that I might substitute this by acetic acid as a cheaper medium. Would Mr. Grey or some other intelligent reader say if this is so, and what proportion should I adopt in order to obtain an equivalent strength of acid?—Mineral Water.

[56879.—**Ferrotype Photograph.**—I have a ferrotype photo which, by some accident or other, had some water spilt on it, and on my wiping the plate some parts of the picture turned black as if it was smeared with ink. Could any of our readers kindly tell me what I could do, so as to remove these black stains, and make the photo. the same as it was before?—Misfortunate.

[56880.]—**Pyroligneous Acid.**—Could some of your subscribers give me specifications of retorts and fittings for the manufacture of pyroligneous acid? The retorts I propose would be 9ft. long and 4ft. diameter. I should like to know the thickness of metal used, and how the doors and ends are luted, also specification of condenser, and also the still and pans required for making grey acetate of lime?—Chemist.

**The Prevention of Yellow Fever.**—Dr. Domingos Freire, in a recent communication to the *Rio News*, gives an account of the inoculations practised in Rio de Janeiro with the attenuated liquid culture as a prevention against the dangers of contracting yellow fever. From Dec. 22nd last up to March 22nd of the present year, 1,109 persons of different nationalities, and whose ages ranged from one month to sixty years, were submitted to subcutaneous injections in the deltoid region of the arm with the said liquid. All, with the exception of one or two cases, experienced elevations of temperature, varying from 37½° C. to 40° C., frontal headache, pains in the articulations, general indisposition, and, in some, slight epigastric oppression—symptoms which ceased after from twenty to forty hours, and without any medical intervention. In many cases these injections were practised in houses where, a few hours before, deaths had taken place from yellow fever, nevertheless in the cases specified, and under disadvantageous hygienic circumstances, not one single serious accident is said to have happened. Most of the inoculations were performed in the presence of two medical men commissioned by the Spanish Government to specially study yellow fever in Brazil.—*Lancet*.

From a list just published, it appears that during the past year 152 boiler explosions occurred in the United States, by which 254 people were killed on the spot, and 261 others injured, many of them fatally.

The New Guinea Company of Berlin, incorporated on May 17, is preparing to send out, in the course of the present year, scientific expeditions to Kaiser Wilhelm Land and the islands of the Bismarck Archipelago.

A new insect, ravaging the vineyards to even a greater extent than the phylloxera, has appeared in great numbers in some parts of Roumania and Bessarabia. A scientific commission has been sent out to investigate the matter.

There has just been launched from the Low-Water Ship-building Yard of Sir W. G. Armstrong, Mitchell, and Co., a steel paddle-steamer, which is the first of three the builders have in hand for the River Thames Steamboat Company. The vessel, which is named the *Rosalind*, is 100ft. long, 14ft. beam, and her draught of water is 2ft. 9in. Everything is being done to make this line of passenger steamers attractive.

## CHESS.

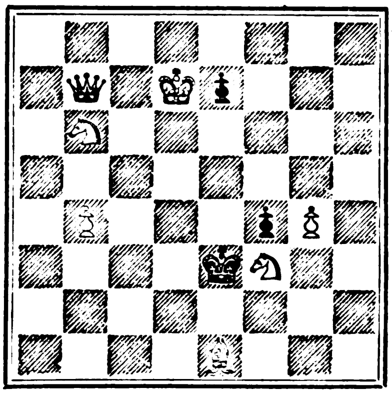
### PROBLEM DCCCCXLIV.—Check.

*Black.*



*White.* [7+3

White to play and mate in three moves.

### Solution to 942.

| *White.* | *Black.* |
|---|---|
| 1. B-R 7 | 1. K takes K P (a) |
| 2. Kt-B 2 | 2. Anything |
| 3. Q or Kt mates | |
| 2. Kt-B 5 &c. | (a) 1. K takes B P (b) |
| 2. Kt-Kt 5 &c. | (b) 1. P takes P |

### NOTICES TO CORRESPONDENTS.

Correct solutions to 941 by F. O'N. H. (For a block position, first move too obvious.—It is, however, more than this.—Ed.), E. Stanley Follwell (rather difficult; Q-Q Kt 2 admits of five or six variations, no duals).

To 942 by F. O'N. H (not too easy, but quite easy enough), R. A. Bennett, A. S. Olver (pretty).

To 943 by E. S., A. S. Olver, R. A. Bennett.

F. O'N. H.—In solution of 940, variation (e) it should be 2 Kt-Kt 5 (ch). We think you have scarcely done justice to 941.

V. S. Pochin.—No mate in your solution if 1.———B-K Kt 3.

A. W. Orr.—942 is quite correct.

J. H. W. C.—It should have been 2Kt-Kt 5 (ch); K-B 4, 3. Q-B 6 mate, if———2 P takes Kt, 3. Q-Q B 7, mate.

Game played in Mr. Nash's tourney, between Mr. Russell (White) and Mr. Gerahty (Black).

(Scotch opening.)

1. P-K 4, P-K 4 / 2. Kt-K B 3, Kt-Q B 3 / 3. P-Q 4, P takes P / 4. Kt takes P, Q-R 5 (a) 5. Kt-Kt 5, B-Kt 5 (ch) / 6. P-Q B 3, Q takes K P (ch) / 7. B-K 3, B-R 4/ 8. Kt-Q 2, Q-Kt 3 / 9. Kt-B 4, P-Q R 3 / 10. Kt-Q 4, K Kt-K 2 (b) / 11. Kt takes Kt, Kt takes Kt / 12. P-Q Kt 4. B-Kt 3 / 13. B takes B, P takes B / 14. Kt-Q 6 (c), K-K 2 / 15. Kt-B 4, R-K sq (d) / 16. Kt takes P, K-B sq (dis ch) / 17. B-K 2, Q takes P / 18. Q-Q 6 (ch), K-Kt sq / 19. Castles, Q takes B P (e) / 20. Kt takes R, R takes B / 21. R-Q 2, R takes R / 22. Q takes R, Q takes Q / 23. K takes Q, P-Q 3 / 24. R-K sq, Kt-K 4 / 25. K K 3, P-K Kt 4 / 26. Kt-B 7, B-Q 2 / 27. R-K 2, P-B 4 / 28. Kt-Q 5, K-B 2 / 29. K-B 2, P-B 5 / 30. R-Q 2, B-B 3 (f) / 31. Kt-B 7, K-K 2 / 32. Kt-Q 5 (ch), K-K 3 / 33. Kt-B 7 (ch), K-B 4 (g) / 34. R takes P, Kt-Kt 5 (ch) / 35. K-Kt sq, P-B 6 (h) / 36. P-K R 3, Kt-B 3 (i) / 37. P-B 4, K-K 4 / 38. R-K 6 (ch), K-B 4 / 39. K-B 2 (j), P-K 5 / 40. R takes Kt (ch), K takes R / 41. P takes P, K-Kt 4 / 42. Kt-Q 5, K takes P / 43. Kt-B 6 (ch), K-B 5 / 44. Kt takes P, K-K 5 / 45. Kt-Kt 5 (ch), K-Q 5 / 46. P-Kt 5, P takes P / 47. P take P, B takes P / 48. Kt takes P (ch), K-B 6 / 49. K-K 2, K-Kt 7 / Drawn game (k).

### Notes by Mr. Gerahty.

(*a*) An unsafe defence.

(*b*) B-Kt 3 probably better.

(*c*) If Kt takes P, Black would be able to castle in a move or two, and prepare for attack.

(*d*) I preferred this to the natural move, P-Kt 4, as being more attacking.

(*e*) An effort to save the exchange would have given Black a bad game, and this move gives him two Ps for the exchange.

(*f*) The B appears to be better posted here than at K 3, being valuable for attacking and defensive purposes.

(*g*) Surrendering the P to get the K into support of the advancing Ps.

(*h*) If Kt takes P / P checks, K-B sq / B checks.

(*i*) Still preventing Kt takes P.

(*j*) Preparing for R takes B, followed by K takes P.

(*k*) Mr. Russell thinks Black might have won by an early advance of Q R P.

## ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, June 17th, and unacknowledged elsewhere :—

C. P. WHITE.—Col. O'Hara.—Gestrum.—B. of T.—J. Boggis.—R. Collyer.—W. G. Penny.—Barnett and Foster.—Tee Bee.—F. Stones.—J. C. L.—Subscriber.—Little Dorritt.—C. A. W.—Souter.—F. C. P.—T. L.—J. Jones.—A. H. and Co.—Rev. R. L.—De Vigne.—Settler.—B. W. G.—Old Rex.—Jura Alf.—Windy.—Structural.—B. N.—Volvox.—Pall Mall Electric Association.

**CHARCOAL FOR FILTER.** (Yes, animal charcoal is used for filtering water, but it is not necessary. See the description by Prof. Guthrie of his "penny water cleaner" on p. 61, No. 965. It consists of a large flowerpot, filled with bits of clean well-burnt brick.)—**INQUIRER.** (Must first know what the eruptions are like. A little potash would do no harm, and you can obtain that very pleasantly in ripe fruit and lime juice.)—**AMATEUR ELECTRICIAN.** (Kindly look through the indices. We really have had almost enough about electric lamps for use in private houses.)—**A RECENT SUBSCRIBER.** (See the indices, or pp. 257, 274, 317, last volume, and p. 5 of the present. There is no practical book on the subject.)—**ROVER.** (How is the steam exhausted after driving the pistons outwards?)—**DR. BRENCHLEY.** (Neison's "Boat-building for Amateurs," Gill, 170, Strand, W.C.)—**J. J. N.** (See the lists issued by the booksellers. It would be invidious to mention any one of the many books on the subject as the best.)—**A COUNTRYMAN.** (See Hints No. 4. Rope ladders, ropes with a sling, and strong tubes of canvas are all used.)—**COLONIST.** (Rubber stamps are made by taking a plaster cast of the type, and pressing into the cast a compound of rubber and sulphur, which is then vulcanised by the aid of pressure and heat, in an apparatus resembling a dentist's vulcaniser.)—**EDWIN G. CAMP.** (We have noticed that group on p. 227.)—**ENQUIRER.** (See the indices, or examine an equatoreal. You do not see the movement in the sketch sent because it is not there.)—**ELECTROTYPE.** (See the indices. They are produced by what is known as the zinc process.)—**DIZZINESS.** (If "different doctors" have failed to give relief, how is it expected that a query in our columns would help? The answers would probably be "bile" in the one case and "hard wax" in the other.)—**BACCHUS.** (In any of the newspaper guides—Mitchell's or Sell's.)—**CEMENT.** (Marine glue, shellac. If vulcanised, clean the brass thoroughly and cut a fresh surface to the rubber, which slide on. Weight down for a few hours, and it will probably adhere with sufficient tenacity.)—**MILK.** (Salicylic acid, we believe, is used.)—**ANOTHER ANXIOUS ONE.** (Given many times. Glue one part, glycerine four parts; sufficient whiting to colour it, and a few drops of carbolic acid.)—**SANITARY.** (Animal charcoal is made by submitting bones to a red heat in closed vessels, so as to exclude the air. So far from being a waste refuse, it is a commercial product.)—**W. S. F. S.** (The phonograph has been described several times. In No. 683 you will find full directions for making one. A patent agent will supply you with the number and date of Edison's specification on payment of his fee for the search.)—**LONG SIGHT.** (You will find the advertisement in No. 1048. The prices given are—Power 4, 50s.; 7, 82s.; and 10, 181s. The 7-power in brass is 39s.)—**CHARLES BEAVIS.** (See indices and recent numbers, and read up the subject. For your purpose a battery would be cheapest in the long run, unless you have a steam-engine to drive the dynamo.)—**GEO. WHEELER.** (We have not a copy of the Latin Version by us; but no doubt the clergyman of your parish has a copy.)

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk, Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists, London."—Also makers of Epps's Chocolate Essence.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and CO., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., and XL., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

NOW READY,
HANDSOMELY BOUND IN CLOTH,
VOL. XLVII.
of the
BUILDING NEWS,
PRICE TWELVE SHILLINGS.
Order at once of any Bookseller, as only a limited number are bound up.

# THE NEW ESTABLISHMENT OF
# THE MEDICAL BATTERY COMPANY, Ltd.,

52, OXFORD ST., LONDON, W. (former address, 205, Regent St., W.)

Sole Proprietors of **DR. CARTER MOFFAT'S "AMMONIAPHONE"** (Harness' Patent, see below.)

**Write for the History of the AMMONIAPHONE, 80pp. 4to. post free.**

The enormous demand for Dr. CARTER MOFFAT'S AMMONIAPHONE, consequent on its extraordinary popularity throughout the Medical, Clerical, Musical, and Dramatic professions, has resulted in such an enormous expansion of the business, hitherto carried on at 205, Regent-street, London, W., as to necessitate the acquisition of more commodious premises. Accordingly, the freehold of the handsome and spacious premises, 52, OXFORD STREET, LONDON, W., has been secured, and no expense spared in fitting up the laboratories, reception, and consulting rooms in the most *recherché* manner. New and elaborate machinery has been laid down, and the Medical Battery Company now anticipate no difficulty in meeting the rapidly increasing demand for the Ammoniaphone, the popularity of which has hitherto taxed their manufacturing resources to the utmost, and has proved a veritable *embarras des richesses.* So intense has been the interest excited throughout the civilised world by Dr. Carter Moffat's unique and interesting discovery, and so universal is the confidence in its merits, inspired by the incontrovertible testimony that has been received from the highest medical, scientific, and artistic authorities, that telegraphic orders have been received from the most remote quarters of the globe, including Honolulu, Hayti, New Zealand, and South Africa; one firm in Cape Town stated, when ordering a supply, that they had orders booked for upwards of 200 instruments. Dr. CARTER MOFFAT will be in daily attendance at 52, OXFORD STREET, to demonstrate the extraordinary utility of his invention for strengthening, enriching, and beautifying the voice, and relieving BRONCHITIS, and all PULMONARY AFFECTIONS.

**WILL LAST A LIFETIME. Price 21s., post free.**

What is the AMMONIAPHONE? In the course of a long descriptive article, *Knowledge*, on the 6th March, 1885, says:—"Dr. Carter Moffat's Ammoniaphone is one of the most remarkable inventions of the day." It is a tube about 25in. long, constructed of a specially-prepared non-corrosive metal, with handles, having patent spring valves. It is charged with a chemical compound, composed so as to resemble in effect that which is produced by the soft, balmy air of the Italian Peninsula when inhaled into the lungs, hence the term "Artificial Italian Air."

Dr. CARTER MOFFAT'S AMMONIAPHONE has proved of the utmost value in the treatment of Coughs, Colds, Clerical Throat, Bronchitis, Asthma, Consumption, Aphonia, or Loss of Voice, Deafness resulting from Colds, all affections of the Throat and Chest, and Sleeplessness. Such ailments may be entirely overcome by means of this simple and beneficent invention.

Dr. CARTER MOFFAT'S AMMONIAPHONE will last for years. It should be used by Actors, Vocalists, Clergymen, Public Speakers, Parliamentary Men, Readers, Reciters, Lecturers, Leaders of Psalmody, Schoolmasters, Amateurs, Church Choirs, Barristers, and all persons who have to use their voices professionally, or who desire to greatly improve their speaking or singing tones, producing a rich, powerful, melodious voice, of extraordinary ringing clearness and range. A poor, weak voice becomes rich and massive, while great good is done to the general health.

"Those sing who never sang before,
And they who sang now sing the more."

## Dr. CARTER MOFFAT'S
# AMMONIAPHONE

AMMONIAPHONE

Reduced *fac simile* of Ammoniaphone.

Will last a LIFETIME.

## DR. CARTER MOFFAT'S
# AMMONIAPHONE.

**5,000 TESTIMONIALS have been received from the leading Vocalists and Amateurs, from which the following are selected:—**

**Madame ROSE HERSEE,** the distinguished English Operatic Soprano, writes:—"Lee-place, 102, Lee High-road, Lewisham, S.E., April 4, 1885. Dear Sirs,—Although at one time strongly prejudiced against DR. CARTER MOFFAT'S AMMONIAPHONE, I am bound by a sense of justice to say that I have found it a most valuable invention. Recently it enabled me to conquer a prolonged hoarseness, which threatened to prevent my fulfilment of an operatic engagement. I have also tried its effect on some of my pupils with striking success."

**CHARLES WYNDHAM,** Esq., Criterion Theatre, Piccadilly, Jan. 15, 1885, writes:—"I have now used the AMMONIAPHONE which you forwarded me about a fortnight ago, and, although rather sceptical at first, I am bound now to confess it is of very great service to me."

**Rev. W. HAY M. H. AITKEN** writes:—"14, Bryanston-square, London, W.—Will you kindly recharge my AMMONIAPHONE? I have derived much benefit from its use. It certainly does clear the voice in a remarkable way, and enables me to get through my work, preaching two or three times a day and sometimes oftener, with much less trouble and fatigue."

**LADY MACFARREN** (wife of Sir G. A. Macfarren, the distinguished President of the Royal Academy of Music) writes:—"7, Hamilton-terrace, N.W., Oct. 22, 1884.—I consider the AMMONIAPHONE to have a wonderfully bracing effect on the vocal organs, and shall have great pleasure in recommending it to such as have weak or relaxed throats; indeed, I have already done so."

**The Very Rev. DR. VAUGHAN,** Dean of Llandaff, writes:—"Nov. 5, 1884. Dear Sir,—My voice has now nearly recovered its tone, and I have certainly derived benefit, though not suddenly or rapidly, from the use of your AMMONIAPHONE."

THE DOCTOR'S VERDICT.

**A. S. KENNEDY,** Esq., L.R.C.P., L.R.C.S., &c., writes:—"14, Conduit-street, London, W., Dec. 20, 1884.—The two AMMONIAPHONES that I had from you have given very good results. Apart from improved timbre, resonance, and extension of register, which are undeniable, I have found the AMMONIAPHONE most useful in cutting short catarrhal and laryngeal troubles, and of great benefit in removing huskiness. Several patients have tried the AMMONIAPHONE at my suggestion, and are all pleased with the improvement in their voices."

**NOTICE.**—DR. CARTER MOFFAT attends daily at the Rooms of the MEDICAL BATTERY COMPANY, Limited, 52, Oxford-street, London, W., to demonstrate the extraordinary utility of the AMMONIAPHONE. Write for "The History of the Ammoniaphone," 80 pages, post free. DR. CARTER MOFFAT'S AMMONIAPHONE (Harness' Patent) will be sent Free by Post to any part of the United Kingdom on receipt of P.O.O. for 21s., payable to C. B. HARNESS.

THE MEDICAL BATTERY COMPANY, Limited, 52, Oxford St., London, W.

# THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—King Mendham. and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—King, Mendham, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 31s.—King, Mendham, and Co., Bristol.

**Wimshurst Influence Machine**.—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—King, Mendham, and Co., Bristol.

**Ice Machine**, make half-ton day, in splendid order, bargain.—H. Harris, Union-road, Ryde.

**100ft. Glass**, cut to size, 12s. 6d. Pamphlet on Polariscope, 3 stamps.—Holmes, 149, Essex-road.

"**American Brand**" Dry Plates (Registered). Amateurs and professionals should send for particulars of these remarkable plates.

"**American Brand**," as above, dozen, postage paid, for 2s.—From Hunter and Co., Stockton-on-Tees.

Brass **Pentagraph**, by Jones, 60s. Harmonigraph, 50s. Powerful Medical and Rhumkorff Coil, 25s.—99, City-road.

Also 10-sq., Bellows Studio **Camera**, with swing back, and large portrait lens by Powell and Lealand, £8 10s.

Patterson's **Ammeter**, 50s. Thomson's Reflecting Galvanometer £4; Browning's arc lamp, 30s.—3, Essex Villas, Fillebrook, Leytonstone.

Model Portable **Engine**, new (Wood, London), cost 12 guineas, slide-valve, cylinder on top boiler, safety valve, beautifully finished, works splendidly, boiler on brass wheels, £3 17s. 6d.—Fritz, 39, Essex-road.

**Liverpool Astronomical Society** —Just out; Vol. III. of the "Journal," 140pp., illustrated by 40 lithographs and wood-cuts, and containing 100 papers on astronomical subjects, index, &c. Stiff paper 4s., post free. May be had of the Secretary, 41, Irvine-street, Liverpool.

Model **Engine Castings**.—Best and cheapest. See list (stamp) and compare.—Wood, Dalley-street, Broughton, Manchester.

**Violin** for sale, magnificent solo tone, perfect preservation, labelled "Antonius Stradvarus 1690," lock-up case and bow, suit lady or gentleman, only 25s. Cash needed, approval with pleasure.—Mrs. Jones, 50, Myddelton-street, Clerkenwell.

"**English Mechanic**," Vols. I. to XXX., good condition, (14 volumes bound in cloth), must be sold at great sacrifice. Any offer likely to be accepted.—W. N., 79, Hare-street, Bethnal-green.

**Stop Diapason**, well made, finished all but feet and voicing, £2.—"Bath Arms," Weston-super Mare.

**C. Pilkington**, 32, Sackville-street, Piccadilly, W., Magic Lantern Artist and Photographic Colourist.

Magic Lantern **Photograph Colouring**, finely and artistically done, 12s. per dozen. Special terms to the trade on application.—C. Pilkington, 32, Sackville-street, W.

**American Organ**, by Bell, first make, having beaten all others in competition; grand tone, 4 sets reeds, 11 stops, patent grand expression and knee swell, 17 guineas; free trial.—W. Hands and Co., Bedford.

**Character Read by Lines of the Hand**. Chart explanation, 7d.—H. Wyke, 21, North-street, Taunton.

Odd **Spiral Springs** made to order. Mattress Springs, 9d. per dozen.—James Parish, 52a, Bard-street Park Sheffield.

**Batteries** (to the trade).—Pint Bunsen's, Bichromate Daniell's, 8s. per doz. Other sizes in proportion.—Below.

**Electro Motors**, 14s., 24s., 78s. per doz. List free.— J. Hanks and Son, Seaforth, Liverpool.

**Electro Motor**, free 2s. 3d., with Battery, 3s. 6d Model Engine, 1s., free. Not approved money returned.—Below

**Batteries**.—Bunsen's, Daniell's, Bichromate, 1s. each in box, 1s. 6d., post free.—Hailey, Novelty Stores, Seaforth Liverpool.

4in. **Slide-Rest**, unplaned, 7s.; ditto, planed 16s. 6d. Perfect Castings from newest patterns.—William Gladstone, 18, Lovatt-street, Stafford.

**Harness Oil**, best, 3s. 6d. per gallon.—PINNELL Brothers, 214, Whitechapel-road.

Powerful **Electro Motor and Medical Coil**, perfect order, carriage paid, 3s.—W. K, 71, Vine-street, Coventry.

Vols. XIII. to XX. "**English Mechanic**," 2s. each, good condition, monthly parts.—G. Wessley, Waterloo-road, Aldershot.

**Treadlé Saw Bench**, all iron, fence and angle guide, good condition, £6.—98, King's-road, Camden-road, N.W.

**Launch and Other Engines**, Boilers, Propellers, Lathes, and all kinds of machinery cheap.—S. Smith, 11, West-street, Soho, W.C.

**Patents, Designs, and Trade Marks**.—Special terms quoted to English Mechanics referring in their enquiry to this column.—F. M. Rogers, 21, Finsbury-pavement.

**Brass Scrolls** to Design, Tube Bending, &c., Copper and general Brass Work (medium size) turned and finished. Terms moderate.—Write Portsous, 32, Brewer-street, W.

**Fistula** cured without operation.—Electric Herbal Ointment, free for 13 stamps.—Jamieson Bros., Covent-garden, London.

**New Time**.—Alter your Clocks and Watches. Twelve Sets of figures, with instructions, 6d.—Wheeler, Preston.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings**.—Improved Registered Designs; sets 4in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors**.—Complete one horse-power. £9 Half, £6; Quarter, £1; Eighth, £3.—Thomas Wheeler, Preston.

**Gas Engine**, 3-man, Barker's Patent Universal, good as new, £28. All my extra fittings.

Also Patent **Band-Saw Machine**, on stand, two saws, hand or power.—10, Darby-road, Folkestone.

**Arc Lamps**, very simple, work with small dynamo, 100 c.p., carriage free, 6s.—Hasgood.

**Wheatstone's Bridges**, accurate, 3s. 6d., carriage free.—W. Hasgood, Hazlebrook, Buccleuch-road, West Dulwich, London, S.E.

**Standard Ohms**, 2s. 6d. each. Delicate Galvanometers, astatic, 5s.—S. Bottone has a few for Sale.

**Am-meters**, indicating up to 8 amperès, 5s. Voltmeters, 5s. Model Electro-Motors, 5s.—S. Bottone.

**Wheatstone's Bridges**, accurate up to 1,000 ohms, 5s each, post free.—S. Bottone, Stanley-road, Carshalton.

3in. centre **Lathe Heads**, several for sale, cheap, new.—C. Pool, Tool Maker, 30, Hockley, Nottingham.

3½in. back-geared **Heads**, hardened double coned, steel mandrels, phosphor bronze bushes.—Pool, as above.

Steel **Name Stamps**, 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d. per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**To Joiners**.—Remaining stock of small Ironmongery bought cheap. Brass cupboard knobs, blind racks, buttons, escutcheons, hinges, holdfasts, 180 latches, complete (3d each). 19 good door locks (cost 2s. 6d. each), for 35s.; padlocks, &c. Particulars on receipt of stamp.—J. N. D., Tuxford, Notts,

100-light self-regulating **Dynamo**, two 30-light Machines, one 5-light fine Brequet Hand Machine, several Motors, and large stock of Woodhouse and Rawson 20 c.p. Lamps, Cable Switches, &c. Low prices; all warranted.—Prices, testimonials, write, Warne, 39, St. John-street-road, E.C.

**Orange Champagne**.—How to make this delicious beverage equal to champagne at 3½d. per gallon. Recipe, 7d.—Below.

**Horehound Beer**.—How to make excellent Horehound Beer at 3d. per gallon. Recipe, 7d.—Below.

**Black Beer**.—How to make this excellent Beer at 8d. per gallon. Recipe, 7d.—Below.

**Vinegar**.—How to make the best Vinegar at 8d. per gallon. Recipe, 7d. All four, 18d.—James Hall, 17, Allhallowgate, Ripon.

**Lathe**, self-acting. 5⅜in. centre, with change wheels, £9. Boiler, vertical, full 1-horse, £6; Launch Boiler, 3-horse, £9; Combined Engine and Boiler, 2-horse, £17.—79, Dudley-road, West Bromwich.

"**Engineering**" for the year 1877, price 10 shillings, "Cassell's Technical Educator," 7s. 6d. The above are all complete, ready for binding.—J. S. Bonnaad, 18, Holgate-road, York.

**Galvanometer**, suspended Astatics four circuits, for strong or weak currents, handsomely got up, silver-plated, with glass shade, 30s.—A. Mathieson, Glebe-street, Falkirk.

**Parallel Vice**, 3⅜in., solid steel patent box screw, as new, cost 27s., price 18s. 6d.—Hawkins, Towcester.

3¼in. **Lathe**, American hollow spindle, 30in. bed, on iron table stand, with polished ash top, 3-speed wheel, fret saw attachment, and sundry chucks; cost £6 15s., price £4; perfect as new.—H. D. Hawkins, Towcester.

**Pianofortes** by all makers at 25 to 35 per cent. discount.—Dauncey, Stroud.

**Pianoforte**.—A good Pianette, walnut, warranted 14 guineas.—Dauncey, Stroud.

"**See-Saw**" **Waltz**, post free, 1s. 4d. All music at one-third marked price, post free.—T. W. Dauncey and Son, Music Sellers, Stroud, Gloucestershire.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, JUNE* 26, 1885.

## TOOLS AND CUTTER-BARS.—IV.

BEFORE speaking of the very necessary and important matter of grinding and shaping cutters, I will reply to the recent query of a correspondent who asked what depth of cut can be taken. Not caring to rely upon my own experience with a light ½in. bar, I requested my kind friend and ally, "J. K. P.," to put matters to the test, feeling that his dictum would satisfy most of our readers, if not all. The result is most satisfactory—to wit, a shaving over 2ft. long, cut from a 1⅝ bar of ordinary rolled iron, the depth of cut 1-9th of an inch, the feed 80 to the inch, and the remark is added: "I have no doubt I could cut 70 to the inch in another and a stronger lathe." There is, in fact, no reason why a cutter securely held in a bar should not do as much work as if it formed the end of a cranked tool, which, with its holder, it actually becomes; and it is because such a cutter being a straight bar is easier to grind than a cranked tool that these bars are so convenient. But in addition to this advantage is the unquestionable one of facility in adjusting the height and position of the cutting edges, and the bar which does this the best is the one that should bear the palm. The question of grinding cutters naturally occupied the attention of Mr. Haydon at a very early period of his experiments; but it was "J. K. P." who, I believe, solved the difficulty in such a way as to give the double-edge system a fair chance of acceptance with practical mechanics. No gimcrack contrivances would do. The ordinary shop grindstone must be pressed into service with some simple and easy method of controlling the angles as the grinding proceeds. Gauges for the pocket might be added, but so far as possible the workman must be as independent of these as if he were grinding an ordinary solid lathe tool. The method that suggested itself to "J. K. P." was the use of a board resting on the bearers of the grindstone, of such thickness as at once to give to the tool the requisite clearance on its lower faces. The angle desired for this purpose could thus be obtained without further measurement, or special attention on the part of the workman. But in order to obtain a given angle, even in this way, the cutter must be raised to a certain height in the sling; and the higher it is placed while the shank lies upon the before-named board or rest, the greater will be the clearance given to the cutter, provided the rest raises the tool above the level of the centre of the axis of the stone. This will be seen on reference to Fig. 39, where A represents the grindstone, and B C D the level of its centre. Then the spaces between the dotted lines may represent tools *a*, *b*, *c*, *d*, *e*, lying end on, at various heights for grinding. All above the axis will be more ground towards their lower surface—i.e., with more clearance, each as it stands higher, and all below will be ground nearer the upper surface—i.e., with less clearance.

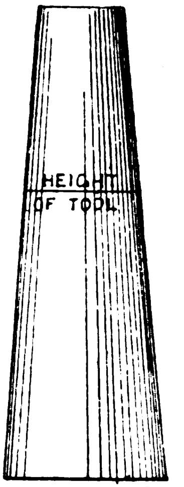

FIG. 43

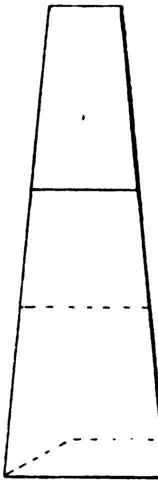

FIG. 44

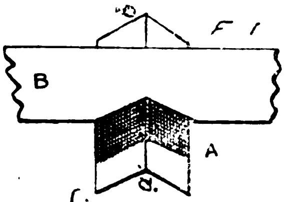

FIG. 45.

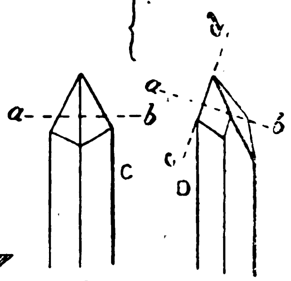

FIG. 46.

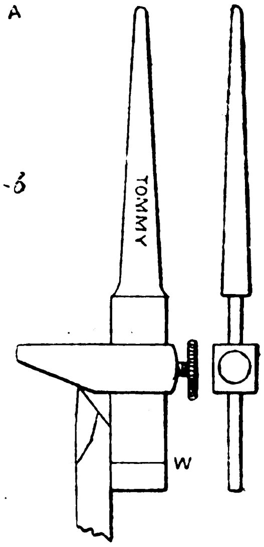

FIG. 42

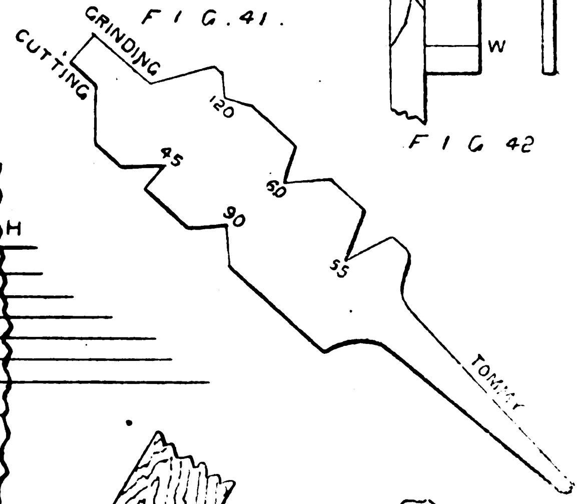

FIG. 41.

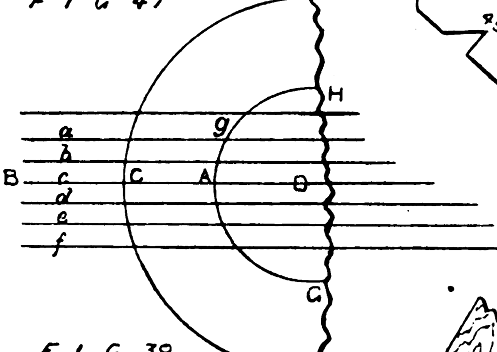

FIG. 39

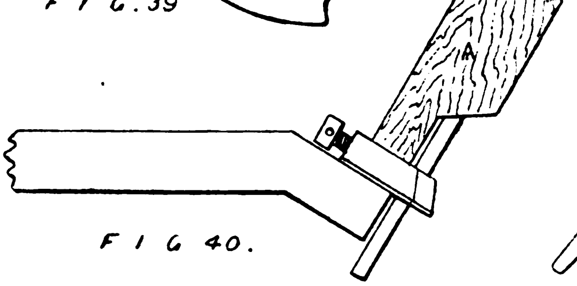

FIG. 40.

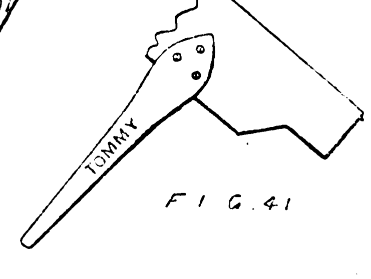

FIG. 41

Hence, in arranging the grinding block or board (say, 3in. wide), matters must be so arranged as to insure the correct position of the tool. It may be necessary to cut down the water-trough or bearers, and then to fit the block; but in any case, it will be a matter of experiment to find the correct height or thickness of block, and also the height to which the cutter must be raised above the sling of the bar. When this has once been ascertained, a very simple gauge will insure such height being kept; and when it is thus determined how high the cutter must stand to get a clearance of 3°, nothing will be easier than to increase or reduce it at pleasure. Some one asked, in a recent number, whether the wear of the stone would not upset the calculations as to the clearance angle. To answer this, I have added the circle H A G to represent such worn stone, and the effect is evident. The tool *g* has plainly more clearance than *a*. But until considerable wear takes place, this is of very slight importance, and can easily be remedied by slightly lowering the grinding block—*b*, for instance, ground on the big stone has about the clearance of *c* ground upon the small one. As, therefore, the stone diminishes in size, the grinding block needs to be planed thinner. It must be remembered that the actual clearance angle may range from 3° to 6°; so that this alteration in the thickness of grinding block need not be very often resorted to. These little theoretical difficulties are of no great importance in practice, being so easily remedied.

A very easy gauge is made by cutting a notch in the grinding block A, Fig. 40, such that when the top of the sling is placed as shown resting on the end of the board, the cutter may touch the end of the notch, supposing it to be raised to the proper height for grinding. For a perfectly new bit of steel, that has not been ground before, it is necessary to set it up a little higher in the sling, as more will eventually be ground off in all probability, in shaping the tool; but the difference will not be great. Mr. Haydon, however, was in the habit of using two gauges. A very useful combination tool is shown in Fig. 41; a gauge and tommy to fit the capstan head of the screw of the bar. I made my own of a broken flat file slightly lowered in temper and ground smooth on both sides. There is a gauge for height of tool for grinding, another for height of tool for use in the lathe, a notch of 120°, one of 55°, one of 90°, and one of 45°, the latter forming edges of 60°, and suitable for cutters to go into corners; another is added of 60°. The tool is 3½in. in length, ¾in. wide, and $\frac{1}{16}$in. thick, and answers all purposes as a pocket gauge. The burnished edges, which are rounded, give it a finish. It was probably a copy of one of Mr. Haydon's; but I have had it some years, and am not quite certain. Of the next two, however, Figs. 41 and 42, I can say positively that they are by the above named amateur, and although useful as adjustable gauges, that can be accommodated to different lathes, I prefer the simpler one already drawn. Only the movable gauge might have two marks for grinding and cutting, as W. and others, for larger lathes.

Now in this there is nothing complicated. Any workman could make such gauges, and if not combined with the tommy, they can be cut out of tin or zinc with even greater ease, as can also (Fig. 43) the cone gauge for the clearance angle, which likewise acts as a test for height of centre, if a line be drawn for that purpose. Ordinarily it is a solid cone of iron or gun-metal turned to an angle of 3°, and large enough at the base to stand firmly upon the lathe-bed. The tool in its bar, if it is one of these, or the shank of the solid tool, is then laid on the table of the rest, and the lower faces of the cutter being brought each in turn against the cone, are thus gauged.

The point of the cutter is then adjusted to the centre line, marked here as height of tool, and can be clamped and set to work. Now it is easier by far to cut and bend a bit of sheet brass, zinc, or tin, like Fig. 44 the sides being at 3° to the perpendicular, and I think it is far easier to test the side *faces* against this thin edge than against the round conical gauge. The latter would test the front *line* easily enough, but I have already explained that this is not what is required. The conical gauge if preferred, however, will be just as serviceable if made of boxwood instead of metal, and will, of course, be easier for an amateur to make. It should be turned with the slide-rest set to 3° and carefully finished. The sheet-metal gauge has this further advantage, that the sides need not be of the same angle. One, for instance, may be 3° and the other 6°, the two extremes allowable for the clearance of metal-turning tools.

These gauges were designed before the plan was arranged of the grinding block already explained. They are, however, useful accessories, and may well be added to the paraphernalia of the workshop.

If this gauge is used with a self-acting lathe, it may be more convenient to stand it upon the saddle of the slide-rest instead of on the lathe-bed. In that case, the line of centres will be lower down upon it, as indicated by the dotted line. We have plainly, in these gauges, a choice which is often convenient. We can use the tommy gauge, and by its means set up the tool in its sling, so that when the bar is placed on the table of the rest, the tool point shall be exactly at the height of the centres, or we can obtain the same result by this cone or plate gauge when the bar is clamped on the tool-holder of the rest. Sometimes we may find the one, and sometimes the other, method preferable; but it is, in all cases, exceedingly advantageous to be able to set the tool at exactly the correct height, without having to test its action upon the work itself.

I have myself seen "D. H. G." grind a tool, set it up by gauge, and at once cut a long clean shaving without the smallest hesitation, as if it were quite impossible that the tool could go wrong, and, after duly imbibing the system, I have done the same scores of times, and so may anyone.

The two points which I have found most important in practice are the clearance and the position of the tools. In most cases, if the work is not satisfactory, it is more probable that the fault is there than in the cutting angle, which may vary a degree or two without material effect on the work. The following edge, too, must not be the sharpest; but although, if any difference exist in this way, the leading edge should be most acute, it is very questionable whether equal acuteness is not the best for nearly all purposes. In taking the measure of an angle, it is very important to make that measurement at right angles to the line which forms the meeting point of the two planes. In Fig. 45, A may represent a bit of folded paper with a gauge across it, which is intended to look as if standing up on edge, only somehow it does not. To measure the angle of the fold, the gauge must stand across at right angles to the line *a b*. C, Fig. 46, is the back of a cutter; *a b* the line of the gauge; and, taking a side view, D, *a b*, the position of the edge of the gauge must be at right angles to *c, d*, representing the line of junction of the two lower faces of the tool—the lozenge-shaped facet on the right hand being the front or top face. If the gauge is not actually up on edge, or if it is inclined in either direction, it will not give the real size of the angle. A few experiments will soon show the workman how to test all the several angles accurately. Amongst other very useful experiments upon the use of tools, is testing by actual trial upon a bar of iron the result of various positions and different angles of edge and clearance. The result will be that if any tool fails to work as it ought to do, the reason of the failure will be recognised from these experimental lessons. The tool may seem to scrape so as not to give a continuous shaving; it may chop—*i.e.*, cut too deep for a second, and then miss, and so on alternately. It may draw into cut so eagerly as to catch and break, or play one or the other of those annoying freaks so well known to the amateur; but his carefully-conducted experiments will lead him in most cases to recognise the cause of failure, and to know the cause, so as to know the remedy. I had overlooked a bar made by Taylor, and exhibited at the Inventionaries, which is on the principle of Tangye's, and of its kind, seems to offer certain advantages. The inclination of the upper face is determined by the vertical angle at which the cutter is placed, and the front or lower face is that which has to be ground. Its peculiarity is that the cutter is put in at the side, and that the tool can cut right up to a large shoulder. Fig. 47 is a sketch of one of these, which will suffice to show the nature of the clamping arrangement. There are other bars by the same Birmingham firm, slightly differing from the above, and one novel pattern for screw-cutting tools. I give the above sketch because of the method here adopted of a side clamp. I do not pretend to decide its claim to superiority over others of its class, but it seems a useful tool. **O. J. L.**

(*To be continued.*)

## ASTRONOMICAL NOTES FOR JULY, 1885.

### The Sun.

| Day of Month. | Souths. | At Greenwich Mean Noon. Right Ascension. | Declination North. | Sidereal Time. |
|---|---|---|---|---|
| | h. m. s. p.m. | h. m. s. | ° ′ ″ | h. m. s. |
| 1 | 0 3 34·05 ,, | 6 42 23 | 23 5 39 | 6 38 48·71 |
| 6 | 0 4 27·74 ,, | 7 2 59 | 22 39 42 | 6 58 31·49 |
| 11 | 0 5 12·93 ,, | 7 23 27 | 22 3 56 | 7 18 14·27 |
| 16 | 0 5 47·07 ,, | 7 43 44 | 21 18 43 | 7 37 57·05 |
| 21 | 0 6 7·90 ,, | 8 3 48 | 20 24 27 | 7 57 39·83 |
| 26 | 0 6 14·29 ,, | 8 23 37 | 19 21 39 | 8 17 22·61 |
| 31 | 0 6 5 76 ,, | 8 43 11 | 18 10 50 | 8 37 5·39 |

The method of finding the Sidereal Time at Mean Noon at any other Station will be found on p. 355 of Vol. XL.

Spots and faculæ of considerable size and beauty continue to appear upon the Sun's face.

At 11 p.m. on July 3rd the Sun is in Apogee, in other words the Earth is then at that point in her orbit which is farthest from the Sun's centre. At this instant we are 93,910,166 miles from the great centre of our Solar System.

There is no real night in any part of the British Islands until after July 20th.

### The Moon

Enters her Last Quarter at 25·6m. after noon on July 5, and is New at 5h. 15·8m. a.m. on the 12th. On this and the subsequent day High Tides may be looked for. The Moon will enter her First Quarter 19·8 minutes after midnight on the 18th, and be Full at 2h. 22·8m. in the Early Morning of the 27th.

| Day of Month. | Moon's Age at Noon. | Souths. |
|---|---|---|
| | Days. | h. m. |
| 1 | 18·6 | 2 45·1 a.m. |
| 6 | 23·6 | 6 32·4 ,, |
| 11 | 28·6 | With the Sun. |
| 16 | 4·3 | 4 4·1 p.m. |
| 21 | 9·3 | 8 2·0 ,, |
| 26 | 14·3 | 11 57·8 ,, |
| 31 | 19·3 | 2 57·6 a.m. |

The Moon will be in conjunction with Mars at 9 p.m. on the 9th; with Saturn at 11 p.m. on the 10th; with Mercury at Noon on the 13th; with Venus 3 hours later; and with Jupiter at 7a.m. on the 15th.

### Mercury

Is an Evening Star during the whole of July, and is very fairly well placed for the observer. About the middle of the month he sets more than an hour after the sun, and may be detected in the twilight over the W.N.W. horizon. His angular diameter increases from 5″ to 7″ between the 1st and the 31st.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 7 3·5 | 24 17·1 | 0 24·7 p.m. |
| 6 | 7 48·5 | 22 59·4 | 0 49·9 ,, |
| 11 | 8 29·1 | 20 52·4 | 1 10·7 ,, |
| 16 | 9 5·0 | 18 12 8 | 1 26·9 ,, |
| 21 | 9 36·5 | 15 14·9 | 1 38·5 ,, |
| 26 | 10 3·7 | 12 9·7 | 1 46·0 ,, |
| 31 | 10 26·9 | 9 6·8 | 1 49·5 ,, |

A Study of the above Ephemeris shows that the path it indicates begins in Gemini, extends across the entire width of Cancer, and about half-way across Leo. Mercury will be in conjunction with Venus (11′ South of her) at 2 p.m. on the 17th, and with Regulus (12′ South of that Star) at 7 a.m. on the 26th.

### Venus

Is an Evening Star during the entire month, setting, like Mercury, about an hour after the Sun. She is now perceptibly gibbous in the telescope. Her angular diameter, which is 10·2″ on the 1st, increases quite imperceptibly to 10·8′ by the 31st.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 7 50·5 | 22 21·6 | 1 11·5 p.m. |
| 6 | 8 16·4 | 21 12·5 | 1 17·6 ,, |
| 11 | 8 41·8 | 19 48·3 | 1 23·4 ,, |
| 16 | 9 6·8 | 18 10·3 | 1 28·6 ,, |
| 21 | 9 31·2 | 16 20·0 | 1 33·3 ,, |
| 26 | 9 55·1 | 14 18·9 | 1 37·4 ,, |
| 31 | 10 18·5 | 12 8·4 | 1 41·1 ,, |

The path of Venus begins on the boundary line between Gemini and Cancer; traverses the last-named constellation, and extends to a point between α and ρ Leonis. Her conjunction with Mercury has been spoken of above.

The night sky this month is, as far as the planets are concerned, a practical blank—**Mars**, **Jupiter**, and **Saturn** all being invisible, and

### Uranus

being pretty low down in the west ere it is dark enough to observe him. In fact, he too is beyond the reach of the ordinary observer during the last 10 days of the month, for which reason our Ephemeris does not extend beyond the first three quarters of it. His diameter diminishes from 3·8″ to 3·6″ before he gets finally lost in the Sunlight.

**Occultations of (and a near approach to) Fixed Stars by the Moon.**

The exceedingly short arc thus described by Uranus while as yet he remains visible lies about two-thirds of the way from β towards η Virginis.

**Neptune**, we might have added above, is invisible too.

**Shooting Stars**

may be watched for on the nights of the 17th, the 20th, and the 29th of July, respectively.

**Greenwich Mean Time of Southing of Seven of the Principal Fixed Stars on the Night of July 1st, 1885.**

| Star. | Souths. h. m. s. |
|---|---|
| γ Herculis | 9 36 29·81 p.m. |
| Antares | 9 42 0·33 ,, |
| $\alpha^1$ Herculis | 10 28 54·81 ,, |
| α Ophiuchi | 10 48 3·09 ,, |
| γ Draconis | 11 13 19·61 ,, |
| Vega | 11 52 19·75 ,, |
| ζ Aquilæ | 12 19 20·06 ,, |

The method of finding the Greenwich Mean Time of Southing of either of the Stars in the above list for any other night in July, as also that of determining the local instant of its Transit at any other Station, will be found on p. 356 of Vol. XL.

## THE INTERNATIONAL INVENTIONS EXHIBITION.—VIII.

### Chemistry and Chemical Manufactures.

THE Chemical Department of the Inventions Exhibition is not so large, and perhaps scarcely as interesting, as the similar department has been in other exhibitions; but the contributors are, in most cases, representative firms, and the exhibits are fairly typical of the direction taken by chemical invention of late years. The stall which first claims attention is one on which are exhibited a number of samples illustrative of the alkali manufacture, and the recovery of sulphur from the vat-waste of the Leblanc process. The names of L. Mond, Jas. McTear, Brunner, Mond and Co., Bell Bros., Gaskell, Deacon, and Co., J. C. Gamble and Son, &c., appear as the joint exhibitors on this stall. Besides an interesting series of samples showing the manufacture of soda, &c., in different stages, there are some fine specimens of chlorates. A model of McTear's revolving furnace is to be found near at hand, and close by are some admirable models of the plant used in Weldon's process for the manufacture of chlorine. The most recent method of the latter ingenious chemist consists in adding powdered magnesia to hydrated magnesium chloride, fused in its water of crystallisation. An oxy-chloride of magnesium is thus formed, which, on being heated in a current of air, splits up in accordance with the equation : $MgO + MgCl_2 + O = 2MgO + Cl_2$. The hydrochloric acid, which is always produced in practice, is washed out of the gas in the usual way, and the magnesia serves for another operation. Some pretty specimens are shown in connection with Muspratt and Eschellmann's patent for manufacturing chlorates, and Messrs. Boake and Co. exhibit liquified sulphur dioxide and various metallic sulphites. Messrs. May and Baker have an interesting stand, on which are a number of beautiful specimens, including various metallic oleates, a fine specimen of metallic bismuth, and tablet camphor in large and perfectly transparent blocks. Messrs. Howard and Sons show various preparations from cinchona bark, and Messrs. Hopkin and Williams have a number of interesting exhibits, some of which are remarkable for their beauty. Among them may be specially mentioned some sulphocarbolate of zinc in crystals resembling arragonite, hydriodate of quinine in beautiful orange crystalline needles, fine colourless crystals of cantharidin, and pure urea in very beautiful needles. A very fine collection of sulphocarbolates is also shown by Messrs. F. C. Calvert and Co., who also show four brands of crystallised carbolic acid, melting at 85°, 95°, 104°, and 108° F. respectively, while the carbolic disinfecting powders range in strength from 5 to 50 per cent. of carbolic acid. We believe in the case of the stronger powders the absorbent used is kieselguhr. A remarkable exhibit is that of Messrs. Burt, Boulton, and Haywood, besides models of their improved apparatus for creosoting timber, according to which the timber is immersed in the creosote oil, heated somewhat above the boiling point of water, while a vacuum is maintained, which results in the effectual expulsion of all moisture, and, on readmitting the air, the creosote is forced into the pores of the wood in a very perfect manner. But to the pure chemist the beautiful collection of coal-tar products shown by the same firm will be of more direct interest. Among these we would call particular attention to the following specimens : —Dinitrobenzene in delicate tufts of yellowish-white needles, acridial hydrochlorate in golden or brownish-yellow scales, a magnificent specimen of anthracene, lemon-yellow crystals of dichlor-anthracene resembling picric acid, and a beautiful fluorescent solution of six drops of dichlor-anthracene sulphonic acid in one quart of water. A specimen of anthraquinone in magnificent, extremely long, delicate lemon-yellow needles should be noticed, and also one of chrysoquinone in minute needles of a deep red colour. A specimen of alizarin in orange-red needles of the colour of bichromate of potassium should also attract attention. The British Alizarin Company show a series of interesting specimens connected with their manufacture. Messrs. Brooke, Simpson, and Spiller likewise exhibit some coal-tar products, as do Messrs. Levinstein, Campbeli, and Co. An interesting collection of seaweed products, shown by the British Seaweed Company, exhibits, in a striking manner, the industry with which Mr. E. C. Stanford has investigated the somewhat unpromising subject of algin. We are glad to hear that this curious body is now used for dressing cloth and cotton thread, and is employed as a dung substitute in calico printing. The collection of metallic alginates is very complete, and well worthy of notice. Young's Paraffin Light and Mineral Oil Company, Limited, exhibit certain specimens which are rarely seen. Among others, three different compound ethers of pyrogallic acid, boiling at 253°, 265°, and 285° C. respectively, together with cymol-phenol boiling at 237°, and phlorol boiling at 220°. They also show specimens of the tar bases, tetracoline, cryptidine, iridiline, and leucoline. The same firm show an interesting collection of pure paraffins, ranging from octane, having a density of ·726 and boiling at 255° F., to heptadecane, with a density of ·803, boiling at 568° F, and solidifying at 48° F. Among their exhibits are some pretty artificial flowers moulded in paraffin wax; while a large block of paraffin attracts attention from the number of air-bubbles it contains, and which we should have thought would have prevented it from being selected as a specimen for exhibition. H. Bollmann Condy shows a collection of hyposulphates, including those of copper, manganese, barium, sodium, and potassium, and also exhibits a new disinfectant said to consist essentially of a mixture of permanganate and sulphate of aluminium, and to be capable of yielding a far more concentrated aqueous solution than permanganate of potassium will do. Among other exhibitors in the Chemical Department we may call attention to the stand of Messrs. Mackey, Mackey, and Co., Messrs. Townson and Mercer, E. Packard and Co., and others. The balances of Degrave and Co., and L. Oertling and Co., should be noticed, and the very ingenious airtight taps of Arnold Eiloart should not be passed without examination. Altogether, the Chemical Department of the Inventions is well worthy of careful inspection, and, to those who can appreciate it, will be found highly illustrative of the march of applied chemistry during recent years.

## THEORY AND PRACTICE OF PHOTO-MICROGRAPHY.—II.[*]

By MAURICE N. MILLER, M.D.

LET us now select and arrange our apparatus. We are to use sunlight—we must have a heliostat. Of the almost numberless forms of this, ranging from the most simple to the most complicated, I unhesitatingly give the preference to the simple and inexpensive instrument invented by Mr. Rutherford, and brought to our notice by one of our oldest and most useful members—Mr. D. C. Chapman. This apparatus is familiar to most of you. It is described in *Silliman's Journal*, 1863-65, and I will give the essential features. The works of an ordinary Yankee clock, with balance, are made to rotate a steel mandrel which is inclined so as to present a continuation of our polar axis. This mandrel carries the mirror. The entire apparatus can be made well and solidly at an expense of not more than fifteen dollars. It is easily adjusted, and when regulated performs with sufficient precision for the best work. Secretan, of Paris, makes an instrument on this plan, entirely of metal, which is necessarily less liable to loose adjustment by exposure than one made partly of wood. Inasmuch as we do not work except in pleasant weather, the heliostat of Chapman will remain in adjustment for a long time if properly cared for when not in use.

Time affords me no opportunity to say anything here about the adjustment or regulating of this piece of our apparatus. I cannot refrain, however, in passing, from suggesting that a great deal of valuable time will be saved by carefully regulating the clockwork before attempting to use the heliostat in actual work.

Having adjusted the apparatus, we find the proper position for it on the shelf outside our window, and by some means affix it so that we may always be sure of securing the same position. This is preferable to attempting to box it in, as the storms are almost certain to injure and alter it. The heliostat is so placed that a beam of sunlight the size of the mirror, say 4in. by 8in., is projected against the outside of our stationary window shutter at a point about one foot above the window-ledge. The mirror should be of glass silvered and not covered with amalgam. At this point in the shutter a hole about six inches square is to be made, with cleats entirely around it, inside, so that with buttons we may quickly fasten therein a piece of board, which, as we will see in a moment, will carry our secondary mirror. You will observe that the beam from the mirror of the heliostat will pass through the hole in the shutter at an acute angle, and so on up to the ceiling of the room, and this is precisely where we do not want it. We have got the light into our room, however, and if everything be working as it should the spot of light will remain unmoved for hours. But we want to bend this beam so that it may come through the opening in the shutter at right angles to the same, and so pass on through the microscope, &c. This we accomplish by means of a second mirror, also silvered, placed just outside the square opening in the shutter; this is attached to the perforated board which fits therein. This mirror must be susceptible of movement in two directions, so that we may always catch the beam from the primary mirror, and direct it with accuracy and delicacy as we desire. This is best accomplished by using the arrangement employed in the old solar microscope, and which is also used in solar photography by reflection. Suffice it to say that the mirror with its attachments is affixed to our perforated board so that when the latter is in place we may have the mirror completely under our control, as the rods which accomplish the adjustments pass through the board and terminate in milled heads inside the shutter.

---

[*] A paper read before the Photographic Section of the American Institute.

Our light is at last passing through our shutter and into our room parallel with and above our shelf. The latter must be so adjusted for height that when the microscope is placed thereon and the optical body placed horizontally, the beam of sunlight may pass through the optical axis of the lenses. As to the microscope—the great desideratum is solidity. You will have noticed that this solidity crops out very frequently in my remarks. It is the natural outgrowth of the use of apparatus which the mechanician seems to think cannot combine solidity with delicacy of adjustment.

The microscope should have, first, a mechanical stage; second, a centring sub-stage; and, third, a fine focussing adjustment that does not alter the length of the optical body. The tube of the microscope should be large and short. Schrauer, of New York, makes a special stand for this work, that answers our purpose admirably. Cleats are affixed to the shelf, so that the microscope may be moved to and from the shutter, but remain fixed as far as its lateral adjustment is concerned.

Our beam of sunlight coming through the shutter we will suppose to be about two inches in diameter. Now is our time to correct one of our original defects with the first simple apparatus. The scattering rays must be picked up and be made to arrange themselves in proper order. In a short piece of tubing fastened in the opening in the shutter we slide a second piece of tubing, which, in turn, carries a plano-convex or double-convex lens of nearly the diameter of the sunbeam. I believe nothing is gained by more light; even an inch is probably sufficient, and an achromatic lens here is not only useless, but less servicable than the single glass. This lens should have a focus of not less than eight to nine inches. Immediately in front of this lens, and supported on a little stand, we place a cell containing water that has previously been boiled. This cell is best made by separating two pieces of thin plate-glass by a frame of wood one-half inch thick. Bore a hole in the upper side of the frame, saturate it with melted paraffin, and, while hot, press the glasses against either side of the frame, and keep them in place by means of two rubber bands, or by thin binding wire. This makes the most perfect and permanent cell with which I am acquainted. Just before the beam of light is brought to a focus by means of the lens, another cell should be placed, which must be filled with freshly filtered solution of ammonio-sulphate of copper. This cell may rest on a stand by itself, although a more elegant way is to attach it by a mounting to the sub-stage.

To the sub-stage is affixed a good achromatic objective. A good one-half inch objective answers an admirable purpose, although for special work the condensers of Abbé and others can be used. The microscope should be so placed that when the achromatic condenser is in proper position the cone of rays from the primary condenser, or the plain lens, may just cover the large or bottom lens of the former. This is an important adjustment, and, in order to secure it and at the same time keep the microscope stand immovable, I have added a rack and pinion movement to my primary lens.

It might now be supposed that we might place an object upon the stage and an objective on the microscope and proceed to work; but should we do so we will find that more light will reach our plate from extraneous sources than will pass through the microscope. Several methods have been devised to cut off these stray rays by means of curtains; but they are all cumbersome, unsatisfactory, and inefficient. I have devised a little arrangement which answers the purpose admirably, although it must be seen to be appreciated. I construct a light framework which completely covers the apparatus on our shelf, being of the width and length of the latter, and about 12 inches high. This frame, except the bottom and ends, I cover with heavy straw board. This, if put on wet, glued, and well tacked, will, when dry, be as tight as a drum. These sides are hinged, so that when let down completely expose the microscope and all the accessories, rendering the adjustments of easy accomplishment. One end of the frame (or box, as it now presents) is fastened tightly to the shutter, while the opposite end, through which the end of the microscope tube projects, is covered with broadcloth or velvet, with a perforation and drawing-string through which the tube passes.

Now we may place our object upon the microscope stage. The heliostat has been steadily following the sun, and our light requires no adjustment save an occasional touch of the secondary mirror. The light passes through our first cell and the water absorbs the heat and renders it safe to our valuable objects and objectives. Remove the eyepiece, and, bringing the camera frame into position, proceed to make your adjustments. We find that, standing by the microscope, the ground glass frame perhaps two feet away, the image appears very weak and faint. This is because the light is absorbed by or passes through the ground glass. Inasmuch as our preparatory, yet, final adjustments are made while we are at the microscope and not at the camera, we place a piece of white cardboard in front of the ground glass and projecting the image upon that it is seen clear and distinct. We can remove our blue cell, as we do not require it just now, and proceed with the mechanical stage to find the portion of the object we wish to reproduce. Let me here observe that a good slide of dried human blood makes a splendid object to begin upon—as it will quickly show faults of lighting. This is the time to look out for internal reflections: remove the draw tubes, and varnish the inside of the tube with good negative varnish. When it becomes tacky allow the smoke from a kerosene lamp with the wick turned up and the chimney removed to coat the varnished surface. Or line the tube with paper so varnished and smoked. So cover every surface that you regard as liable to prove troublesome.

Well, everything about the image on the paper screen appears as it should, and we are now prepared to complete the focussing, yet hardly so, for after having replaced our blue cell, shut the microscope in, and move our position to the ground glass, we find we cannot reach the milled head of the fine adjustment of the microscope. So we require to affix a little grooved pulley to our shelf which shall carry a light gum-elastic belt over the milled head of the fine adjustment. The latter should also be grooved to receive the belt. To the axle of our grooved pulley is attached a light rod which passes back to the camera. Now we can assume our photographic position and finish the focussing.

The question will be asked: "How far distant should the ground glass or sensitive plate be from the microscope?" To this question only a general answer can be given. The only thing gained by distance is amplification. And just here you must appreciate the difference between amplification and magnification.

If you desire increased detail in your picture you can only secure it by using higher power in the objective. Do not attempt to make great blurred images by removing the sensitive plate to a great distance. With your screen at a distance of two feet from the microscope stage, employing a first-class one-eigth inch objective, you may get from 800 to 1,000 diameters, ample for your first twelve months work. Indeed, I would advise beginning with a good quarter-inch objective and about eighteen inches distance.

In ordering our steps, you may have noticed that I removed the eyepiece, and I mean to keep it so removed. I have never seen an instance where the introduction of the eyepiece was desirable; and I have seen a great many errors and imperfections introduced by the employment of it. If, however, you will insist upon using the eyepiece, let me caution you—see to it, that no speck of dirt, however small, remains on either lens, for the slightest fleck of dust is sufficient to make an ugly mark on the negative. This precaution should prevail with the mirror surfaces as well. Let them be thoroughly cleaned before commencing your day's work.

Now, how long shall I expose? No earthly intelligence can answer this question for you. You will, after a time, be able to look at the image on the ground glass, and judge with considerable accuracy as to the length of exposure—and it is just this experience alone which will enable you to so judge. With our present facilities, and with moderate amplification, the drop-shutter can be used—although it is better to diaphragm down the light and expose longer. The best exposer is a little flap of velvet hanging over the eyepiece end of the microscope tube, as it may be lifted and the exposure made without disturbing the adjustments. When it is not required it is turned aside, and so held by a hook-and-eye.

Now, in what way can we modify our apparatus, and lessen the expense, without materially affecting the final result? I am perfectly assured of one thing: for results that will prove satisfactory to the conscientious amateur, I believe that the darkened room cannot be dispensed with. Anything short of this is shaky and unreliable, besides tedious, in consequence of the endless running to and fro, from the stage of the microscope to the screen of the camera. With our gelatine plates, for a very large range of work, the heliostat can be dispensed with. It is a luxury, and indispensable if very long exposures are necessary. But a great deal of work can be done with the secondary mirror alone, although the constant adjustments are tiresome. The next absolute luxury—and this is purely so—is the expensive mechanical stage. If the student is prepared to draw liberally on a very large stock of patience, the mechanical stage may be omitted. The modern glass stages, moving, as they do, easily and with ready control, answers fairly well for the more expensive attachment. The centring sub-stage for first-class work cannot be spared. Much low-power work can be fairly done with a plain sub-stage, however.

To sum up, therefore, we may say that a great deal of very fine work can be done in photo-micrography with the secondary mirror, the centring sub-stage, and an ordinary microscope stand. I should rather discourage attempts that had not these facilities in contemplation at least. Much amusement can doubtless be secured with less than I have indicated; but it is not to these idlers in science that I am speaking here.

I desire now to refer to some matters connected with our subject, more especially the outgrowth of my practical work. As to lenses. What objectives are best? I think I can safely say this: As a rule, the lens that is found to produce the very best photo-micrographic pictures will also be an excellent lens for general microscopic work. It is no longer necessary to look for lenses corrected for photography. This idea is a delusion and a snare. If you have a lens that works well on tissues, you need not be afraid to try it on these subjects in photography. If you have a lens specially made to resolve the *Amphipleura pellucida*, why try it on *Amphipleura*, and don't try it on anything else. Occasionally you will find an objective that, for some reason unknown to men and opticians, does excellent photographic work. You order a duplicate, and it is a dead failure. I have in mind an instance in which the great and lamented Tolles made three several and separate attempts to duplicate one of his previous lucky hits, and signally failed. I can—and I say it with regret—only say try. There is no certainty about it. Of one thing you may be sure: a poor, cheap lens will never make successful photographic pictures. I have a one-sixth by Miller Bros., not specially made for photography, which, they frankly tell me, they would not guarantee to copy. The most successful pictures the world has thus far seen have been made with the objectives of Powell and Lealand, Tolles, and Zeiss, although the great master of this art died before he could give a final verdict respecting many of the latter maker's lenses.

From the little I have worked with the very low-priced lower powers of this cunning optician, it seems probable that they will prove most excellent lenses for our purposes. There is no necessity, however, in importing lenses, unless it may be in certain instances where the expense is the most important item, for the objectives of William Wales, of our own city, have produced some excellent pictures, and we owe much to his patient work in the direction of producing lenses for this special work. I must, however, repeat my original opinion, that success will more generally be gotten by trying first-class working glasses than in attempting the construction of lenses specially corrected for photography. I have no special theory on the matter. The statement is made only as a result of experience with very many trials with almost every known maker. For low amplification almost any first-class microscope objective will answer. It is only when the higher powers are required that the striking difference in objectives will be apparent.

It will not be found sufficient to simply attach a lens to our apparatus and proceed, leaving the glass to work out its own salvation. The same delicate correction for thickness of cover, the same careful preparation of immersion fluids, and the same patient adjustments for illumination are required in photo-micrography as in ordinary microscopy.

The introduction of polarised light affords a method of producing beautiful results, especially in photographing rock and mineral sections. The polarising Nicol is placed between the water and the blue cells. It should have a diameter of at least 1¼ inches, and had best be made after one of the modern formulas producing short prisms, as there is always sufficient loss of light in this work without the introduction of unnecessary elements of absorption. The analyser should be as large as is possible to use comfortably, certainly sufficiently, so to cover the posterior combination of the objectives completely; if it be smaller the field is much reduced. The small polarising attachments usually supplied with observing microscopes are totally inadequate to our present needs. The field is too small and the amount of light passing through the combination insufficient.

Respecting photographic processes adapted to photo-micrographic work, it becomes me to say little to such an audience as this. The factors that produce the full detailed portrait negative are only necessary. The rapid working gelatine films will enable the present worker to enter a field that has been entirely unexplored by our predecessors armed with the silver bath alone.

It may not come amiss to say something just here about the microscopic objectives themselves. Each worker will select a field for himself. Diatom pictures, so far, take the lead. It is probable that the great value of photo-micrography in the future will be exemplified in the production of illustrations in the minute structure of living organisms, both in their healthy and diseased states—*i.e.*, normal and pathological histology. The one great feature of our productions in this line is their absolute truth to nature. The pencil of the retoucher is not here available. The pictures are not always beautiful—there is no opportunity to select a fragment here and there, and with perhaps a slight draft on the imagination, as *in the composite* picture for the wood-engraver. *For this reason* rather than the great expense, photo-micrographs have never been very popular as general book illustrations; several beautiful volumes so illustrated on anatomical subjects have, however, been widely distributed among scientists. The inestimable value of our art is already seen in the domain of bacteriological investigations; and already do we look with suspicion upon the engraved illustrations of these minute, though potent, organisms.

The same conditions that produce a beautiful view are necessary in our microscopic object. If we have an object affording plenty of clear, sharp detail in proper colour, we may reasonably expect good pictures. And just here presents one of our most serious difficulties. Microscopic objects are, as a rule artificially coloured. As a rule, however, we are not limited in the selection of our dyes; in certain work we are so hampered. Tissues are dyed or "stained" in order to sharpen the differentiation. The dye attacks one part. of a minute animal of vegetable structure very strongly, while other portions are only slightly coloured. The dyes most commonly used are those made from carmine and logwood. The aniline dyes are also used almost exclusively so in bacteria staining. Carmine-tinted specimens are tolerably well adapted to our work, although the contrasts are feeble. The very best staining for photo-micrographic reproduction for tissues in general, there being no universal process, is that obtained with properly prepared logwood solution, the sections having been subsequently tinted slightly with eosine. Many complaints come to me regarding the logwood staining, and as often employed it is valueless, inasmuch as the resultant tint is blue. This is a fault of the operator, the proper staining containing sufficient non-actinic colour to give good differentiation. For fresh tissues, especially epithelial structures, the litho-carmine with the yellow of picric acid will give good photographic contrasts. Insects and parts of the same are usually unstained, and present sufficient contrasts. The most striking popular productions will be obtained in this direction. In micro-organisms we are, unfortunately, sometimes unable to select our tint. Certain peculiarities of composition render them amenable to particular dyes, and we have little choice. Certainly strong contrasts are not to be expected with extremely minute translucent points or lines of a faint blue tint on a white ground.

America has, so far, taken the lead in photo-micrographic work. Indeed the late Colonel J. J. Woodward, in whose death the scientific world lost an enthusiastic, indefatigable, and highly intellectual worker, was almost the father of high-class photo-micrography. His publications have done more than all other causes combined to stimulate endeavour in this important branch of illustrative art. May I not be allowed to hope that you are not willing to be satisfied with simple mediocrity, but that those now commencing this work will aim, not to only equal what has already been done, but to secure results far in advance? It was in the hope of stimulating such endeavour that I consented to appear here on a subject that is of interest to only a portion of our number.

## BACKLASH IN GEARING.*

EVERYONE who has much to do with machinery is familiar with backlash; but very little has been written concerning the cause of it, or the means of getting rid of it. Indeed, direct and palpable mistakes concerning it have been made by authors who ought to have known better. For instance, Rankine defines backlash thus: "The excess of the space between the teeth of one wheel above the thickness of the teeth of another wheel with which the first wheel gears, is called play, or backlash, because it is the distance through which the pitch line of the driver moves after having its motion reversed before the backs of the teeth begin to act." This is very imperfect and inadequate. Unfortunately, the jarring and rattling of teeth, known as backlash by millwrights, is certainly not the clearance space between two teeth; nor is it met with only when wheels are reversed. If two cogged wheels properly made be run together with a steady pressure there will be no backlash, and and there will be very little noise. The cause of backlash is simply that the pressure is not uniform, and the cure of backlash can only be effected by making it uniform. The old millwright's rule, that the velocity of the rim of a fly-wheel must be in excess of that of the circumference of the millstones, went right to the root of the whole matter; and we propose to show here in a few words what are the special means to be adopted to get rid of backlash. Whether they can be applied in practice or not depends in all cases on conditions over which the engineer sometimes has, and sometimes has not, control.

No matter how heavy the flywheel of an engine may be, it never revolves with a uniform velocity. Its speed falls off as the crank approaches the dead point, and the dead point being passed, it gradually augments until mid stroke or some point near it has been attained by the piston. If the machinery driven is so light that it has not much momentum, then its speed will rise and fall with that of the engine, and there will be no backlash. If, on the contrary, the driven machinery has a good deal of weight and momentum, then there is certain to be backlash. Let us suppose, for example, that a flywheel 15ft. in diameter, and weighing 10 tons, makes fifty revolutions per minute. The average speed of the wheel rim will be 2,355ft. per minute. Let us further assume that the maximum velocity of the wheel is 2,360ft., and its minimum velocity is 2,350ft. per minute. Let the rim of the weeel be toothed, and let it gear into a wheel 5ft. in diameter, weighing 1 ton; the speed of this wheel will be identical with that of the fly-wheel, and its momentum will be too small to help the fly-wheel in any way over the dead point. Its momentum, indeed, will be only one-tenth of that of the fly-wheel. Now, let us suppose that the machinery driven is run under these conditions at a speed too irregular for the required purpose, say, spinning cotton, and that to get over this difficulty the mill-owner mounts a second fly-wheel 15ft. in diameter on the second-motion shaft. The rim velocity of this wheel will be three times that of the fly-wheel, or 7,065ft., and as the controlling power of fly-wheels varies as the squares of their velocities, this second wheel will have nine times the steadying power of the first wheel, instead of only one-tenth of it, as was the case with the spur wheel alone. What, then, happens is that whenever the chain flywheel tends to lag behind, the second motion wheel takes up the running, and the spur wheel on the second motion shaft will actually run faster than the flywheel, and will drag it, the pressure being transferred from the front of the teeth to the back, and the play existing between the teeth will permit them to hammer each other, and so backlash will be set up. The velocity of the second spur wheel will not tend to vary much over 1ft. per minute, while the velocity of the main flywheel tends to vary, as we have seen, 10ft. per minute, and the toothed spur wheel will therefore alternately drive and be driven twice in each revolution. As far as the spinning machinery is concerned, the result may be satisfactory enough, but the backlash will be intolerable. The teeth will be worn out of shape and broken. We have here, of course, a purely imaginary case, the conditions being worse than those which are usually met with in practice; but this is the best way to put an elementary truth, so that it may be readily undsrstood by those who have not much knowledge of the theory of machines. The second flywheel is seldom used out of ironworks, but the equivalent of a second flywheel is by no means unknown. Thus we meet with long lay shafts fitted with numerous heavy spur wheels, running at a high speed, and these are often quite adequate, especially when the load is light, to drag the flywheel after them twice in each revolution. When the load is heavy in proportion to the momentum of these secondary revolving masses, the backlash will be small or absent; and this is the reason that, as is well known, gearing will sometimes run with noise and tremour enough to shake a mill down, while at others it is quite quiet. In one case the load is light, in another it is heavy. Broadly stated, all revolving masses on second-motion shafts which tend to help a flywheel to equalise velocity are liable to cause backlash in spur gearing. The way to avoid backlash lies in taking measures to prevent the load driven running away from the driver.

There are, moreover, other causes which tend to the same end. A frightful source of trouble is want of balance in some part of the machinery. Some years ago a horizontol engine, indicating about 50 h.-p., was put down to drive a corn mill. From the first this engine, which worked expansively, gave trouble in the way of backlash. After much talking and thinking, the manager of the firm by whom the engine was made suspected that the fly-wheel was out of balance. The wheel was unkeyed and swung, and this was found to be the case—probably from an imperfection in the casting; and to make matters worse, the wheel was so hung as to aggravate the want of balance, retarding the wheel when the crank was near one dead point. About 2 cwt. of balance weights were cast and bolted to the rim, when the backlash at once disappeared, and no further trouble was experienced. It may seem that the means adopted were quite inadequate to the end; but it must not be forgotten that the difference between silence and noisy backlash is often very small. A very little hanging back of the flywheel of an engine may suffice to take the cog faces away from each other for a moment, and these, coming together again, will make quite as much noise as is desirable. One other cause of backlash deserves notice, and that is the whipping of long shafts. An instance came under our notice some years ago where two rows of 3ft. 8in. burr stones, fifteen pairs in each row, were driven by two lay shafts, each over 90ft. long. Fine flour could not be made with the stones furthest from the engine, because each shaft whipped nearly one-sixth of a revolution, being too small in diameter for its work. It will be seen that if a weak shaft is interposed between a driving spur wheel and a load, we have all the elements of unequal stresses between the teeth of the gearing at once introduced. It must not be supposed that backlash is confined to cog wheels; in some cases much trouble is experienced in driving with ropes, because the second motion-pulley is so heavy that it helps the flywheel of an expansive engine. The result is that the ropes surge up and down, and may be thrown off. Rope gearing has been used for driving tilt hammers in Wales and elsewhere, but with unsatisfactory results, due to the sudden flying forward of the rope pulleys when the helve trips off the wiper. It may not be out of place to add here that the heavier the flywheel, and the more expansively the engine is worked, the greater is the probability that there will be backlash. It is a favourite notion with some engineers that a fly-wheel cannot be too heavy. The truth is, however, that the wheel should always bear some definite ratio to the weight of the other revolving masses whose momentum tends to render motion uniform. To put once more an imaginary case, let us suppose that on the shaft of an engine two flywheels of equal weight were mounted, the one keyed on the engine shaft and fitted with spur gearing, the other mounted loose and driven from the shaft by a coiled spring or some such flexible arrangement. It requires no great familiarity with mechanics to see that the second, or loose wheel, would soon set up a kind of rhythmical apparent motion with regard to the first, the spring would alternately coil and uncoil as the second wheel was alternately driven by and helped to drive the first wheel; and it is also clear that the lighter either of the wheels was, the more closely would their rates of motion of rotation coincide.

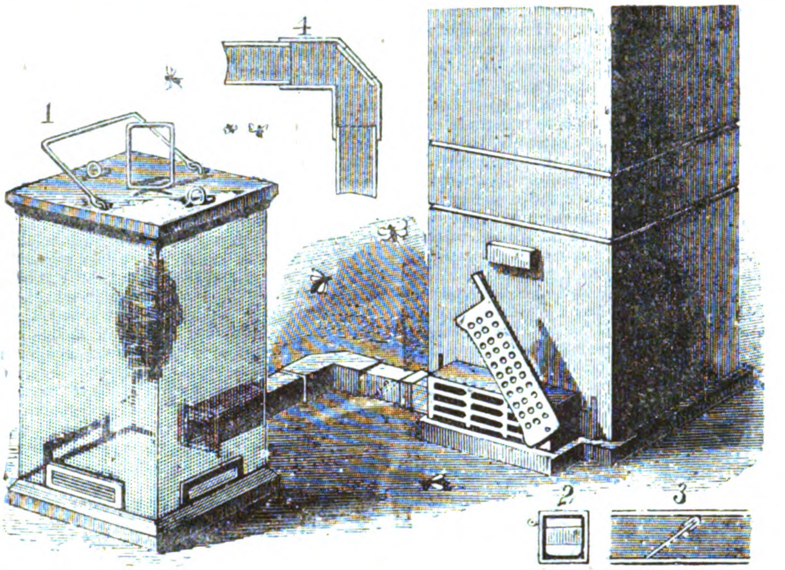
We sometimes hear it said that wheels are running with a great deal of backlash, when there is nothing of the kind. There is a tremendous noise, it is true; but this is due to the bad form or condition of the teeth, and to nothing else. Wheels out of truth on their shafts, or with considerable play in the shaft bearings, cannot run silently; and it should never be forgotten that when a wheel has been properly pitched and trimmed to run with another, if that other gets broken, it cannot be properly replaced by the first wheel of the same pitch that the millowner can lay hands on. Certain firms, we may add, make the production of gearing a speciality; and our readers will find it cheapest in the long run to resort to such firms rather than go to anyone who happens to have a set of wheel patterns handy. Second-rate gearing is the most expensive commodity any millowner can use.

## ACETIC ACID FROM WOOD.

IT is well known that most of the acetic acid sold in the United States is produced by the distillation of wood, but some details of the operation may be new to our readers. The possibility of this method depends on the volatility of acetic acid and the fact that it is not decomposed at a dull red heat. Among other volatile products of this distillation are marsh gas, olefiant gas, and liquid at ordinary temperatures, benzol, toluol, phenol, &c. This distillation is usually carried on in iron ovens or retorts into which the wood is introduced. In some cases the more volatile matters, such as water mechanically obsorbed or contained as sap, are driven off by the application of a lower degree of heat, and in others this is not considered necessary. In some factories wood is treated both for its volatile products, such as acetic acid, benzole, and creosote, and free access of air until carbonised, which is predicated when the smoke given off becomes bluish instead of dark and heavy. The air supply is then shut off and for charcoal. In these the charge is ignited with in place of a clean combustion the decomposition desired by the manufacturer is effected. The yield of acetic acid, as well as of liquid products, with the exception of benzole, in general, is less when the wood is rapidly charred. In operating upon refuse wood, such as sawdust, spent dyestuff, and tan bark, retorts of special form are necessary, as the application of heat is almost immediately followed by the formation of an exterior coating of hard carbon, which effectually protects the interior of the mass from the action of heat. This fact prevented for a time the utilization of such materials, but the difficulty was overcome by exposing only thin layers of material to the heating surface. The retort for this operation consists of a horizontal cylinder of iron, containing for its entire length a screw, which, while moving the materials steadily on by its revolutions, keeps it evenly distributed over the bottom of the retort. The cylindrical retort is so built as to expose the greater part of its length to the heat of a furnace, while at one end is a provision for feeding the material regularly. The other extremity has two branches: one running directly downwards terminates in a tank of water, into which the carbonised substance falls; the other leads to the condenser. Where wood is operated in billets, simple cast or

---

* From *The Engineer*.



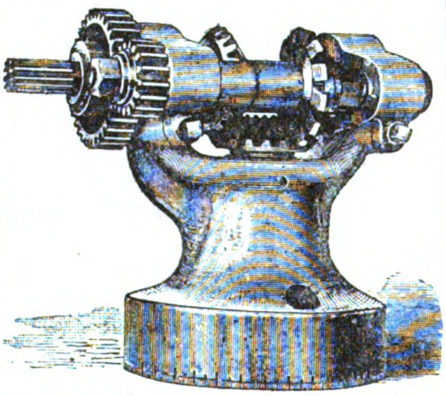
wrought iron ovens capable usually of holding about one-half a cord are used, and the vapours conducted to a suitable condenser. The amount of acid and charcoal obtainable from a given weight of wood varies with the kind of wood employed, but in general may be stated as something under 50 per cent. of charcoal. This acid is the crude product containing tarry and other empyreumatic products known in commerce as pyroligneous acid. It is purified by subjecting to a slight heat, to separate benzole, and saturating the acetic acid with lime or soda. The salt is calcined in order to decompose the tarry matter present, and afterwards distilled with sulphuric or hydrochloric acid, which combines with the base and sets acetic acid free. This part of the manufacture is not always carried on by the distiller of wood, who must, from the nature of his crude material, operate near the source of his supply. Therefore, the acetate of lime is a commercial article from which the manufacturing chemist may produce the acid in question. One advantage of this is that the solid acetate is more cheaply transported than the liquid acid.

## FERGUSON'S COMBINED BEE SWARMER AND HIVER.

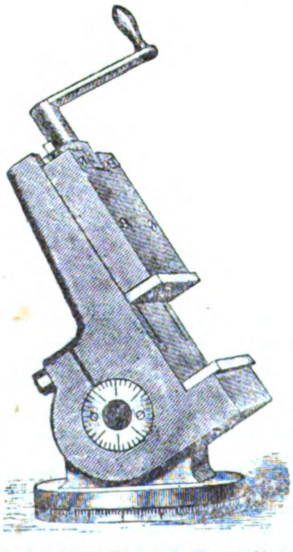
THE object of the contrivance represented in the engravings is to conveniently control the swarming and hiving of bees. It has been invented and patented (in the United States) by Mr. S. E. Ferguson, of Eureka Springs, Arkansas. At the hive entrance is placed a trap, in the rear side of which is an entrance, the size of which can be regulated by sliding gates. By adjusting the slides so that only one bee can pass at a time, the bees can easily guard the hive against robber bees. The front of the trap is provided with a bar door, the spaces of which are large enough to permit the passage of the working bees but not the queen, and also with a perforated door, through which only the workers can pass. These doors are hinged so as to swing open and shut through vertical planes. In one or both ends of the trap is an opening to receive the end of a conductor, the first length of which is made of wire gauze to admit light, so that the queen can readily find her way into the conductor. The second length, Figs. 2 and 3, has a drop door made of mica or other transparent material to transmit light, so that the queen, in seeking to escape, will raise and pass the door, thereby being prevented from returning. When the conductor turns as in Figs. 1 and 4, the elbow is provided with a transparent plate. The other end of the conductor enters the wall of the cluster cage, which is formed with a number of entrances to admit the bees. The wall of the cage is of wire gauze. The lower frame of the cage is permanently attached to a bottom, while the top is formed with slots to receive set screws screwed into the top frame; the top can be secured in place by turning the set screws at right angles with the slots. The handle of the cluster block placed within the cage passes through a slot in the middle of the top, and has a loop at its upper end. The lower part of the loop is at right angles with the cluster block, so that the latter can be supported by turning the loop one-quarter around. The loop also serves as a handle for carrying the block. A bail is hinged to the top of the cage. In using the apparatus the trap is placed in front of the hive entrance, and the perforated door raised to allow the workers and drones to pass. The only passage for the queen to escape by is through the conductor into the cage. The bees then enter the cage through the openings, and cluster upon the block; the swarm can then be readily transported to a hive. If desired, the outer end of the conductor can he connected by another trap with a second hive.

## NEW ATTACHMENTS FOR MILLING MACHINES.

THE vertical angular attachment for milling machines shown in the illustration is especially adapted for heavy milling machines. It is



cast hollow and secured to the head of the milling machine by four bolts. The base has an annular T-slot, and a hole to insert the bolts. It is driven by a socket fixed in the spindle of the milling machine, which is key-seated to fit the keyed stud



in the attachment. Through the medium of a pair of mitre wheels, this stud drives a spindle at right angles to the attachment, and it is geared to a shaft in line with it, which is utilised as a cutter or saw arbor, for cutting racks, sawing-up stock, &c. This shaft runs in gun-metal bearings, and can be removed by means of the two clamp screws in the clamp bearings. This attachment can be used either vertically, horizontally, or at any angle around the centre, the base being graduated to register its position. Cutter arbors or boring bars can be used in either end of the main spindle. For rack cutting there is no limit as to length, while for milling or boring castings of irregular shape or troublesome to hold in ordinary tools, this attachment will be found very useful. In cutting large gears the cutter spindle is placed vertically, and the index head at right angles to the platen; the gear blank is then fed in line with the main spindle of the milling machine. By setting the platen at an angle bevel gears may be cut. Spur gears up to 6ft. in diameter may be cut with this attachment in connection with the heavy milling machine referred to above. This attachment can be utilised for and is adapted to the cutting of racks, spur and bevel gears, profiling or angular milling: boring or drilling at right angles to the main spindle of the milling machine, sawing up stock, milling of slots, links of locomotives, arcs of circles, dies for sheet metal, square pieces on edge, etc.

This vice, represented in the illustration, is adapted to swing from a horizontal to a vertical plane or at any angle therein. A graduated plate with a central stud fills a hole in the base of the vice, enabling it to be set at any angle. It can be held in position on the trunnion by clamping the body of the vice with the two nuts shown in the cut. A graduated dial on the trunnion, marked by degrees, gives the angle to which the vice can be thrown, facilitating the milling or planing of work at an angle. The jaws, of hardened steel, open 8in. with a depth of 2in. In addition to the numerous uses to which this vice can be put on a milling machine, it can be applied to advantage on a planer, shaper, drill press, etc. These milling machine attachments are made by Detrick and Harvey, Baltimore, Md.—*American Machinist.*

## RE-DYEING FADED GARMENTS.*

ALL light-coloured woollen and silk garments especially the former, should be cleaned not hotter than hand heat, and with very little soda in the soap-liquor. When the goods are cleaned and rinsed ready for dyeing, sort them out according to their colours, and pass through an acid bath at boiling heat. For a sixty-gallon copper or bath use ½ pint vitriol, 8oz. oxalic acid, and handle the goods in this for ten minutes; then lift and rinse in two lots of hot water. Observe what garments are the most faded, and after passing through the acid bath, sort them out and keep separate until the scouring is finished. Then add to the acid bath half a gallon nitrous acid, and re-enter the goods which still show the fades, and keep handling them until they are all of a uniform colour. This would not, of course, apply to garments for blue, pink, or grey. In the case of faded white goods for light blue, after cleaning, pass through a bath at boiling heat to which has been added one pint spirits of salts. Work in this for ten minutes, then lift and rinse in two lots warm water; should the goods be required dyed soft, before dyeing pass through a bath at hand heat containing one gill ammonia. Should a greenish shade be required it can be got with indigo, and you can dye direct from the acid bath, adding 12oz. Glauber salts or 1lb. common salt. Dye at boiling heat.

Faded Garments for Grey, Drab, Fawn, and Slate.—If the fades show after cleaning, pass through a bath at boiling heat containing nitrous acid in the proportion of one pint to 40 gallons of liquor. This will cut the fades, and will not give too much yellow body to prevent dyeing a good grey. Some dyers may object to this on the ground that a good grey cannot be dyed on a garment after it is treated with nitrous acid. To this objection my answer is emphatic. I positively affirm that never does an article come into my hands for grey, which is faded, but I treat it with a little nitrous acid as explained above, and with invariably satisfactory results. It matters little what shade of grey is required, as it can be regulated by the proportions of blue and red employed in the dye bath. The principal thing to be studied in dyeing faded garments is the use of the proper drugs. Take for instance an article for marone. If dyed with cudbear, and boiled all the time of dyeing, the faded parts of the garment will turn out much darker than the other parts. If the goods are all wool, dye at boiling heat with acid roseine, acid yellow, indigo, and Glauber salts. There are some classes of goods that cannot be dyed by this method, such as woollen garments trimmed with silk. This class looks much better dyed with cudbear, as the silk and wool will match in the same bath, provided the goods are not boiled.

Faded Damasks for Crimson, Marone, and Claret.—These should, after being thoroughly cleaned and rinsed, be stripped in a bath at boiling heat with spirits of salts and oxalic acid, which will help materially to cut the fades. Rinse in two warm waters, and dye the crimsons with cochineal and cochineal paste (or acid magenta and cochineal), grain spirits, and Glauber salts. The marones can be dyed in the same copper, using acid roseine, acid yellow, and indigo, with a little sulphuric acid. On no account boil the damasks until after they have been in the copper for fifteen minutes. Even after this it is not advisable to boil the goods for long, merely keeping the copper at boiling heat.

---

* From *The Dyer.*

FADED DAMASKS FOR GREENS. — These trouble dyers more than any other colours. The great mistake is boiling them too much. Many dyers labour under the impression that the only way to cover fades in green damasks is to boil them well. I have seen a master dyer, who ranked himself second to none as a thoroughly practical man, boil a lot of damasks over four and a half hours, and then, finding the fades still showing themselves, he declared that they had not been boiled sufficiently. Instead of a lengthy boiling covering the fades, it made them still darker. The best method for greens is to dye them with indigo, acid green, and either common or Glauber salts, together with sulphuric and picric acid. But be sure not to err on the side of too much boiling.

# SCIENTIFIC SOCIETIES.

## ROYAL METEOROLOGICAL SOCIETY.

THE concluding meeting of this society for the present session was held on Wednesday, the 17th inst., at the Institution of Civil Engineers, 25, Great George-street, Mr. R. H. Scott, F.R.S., president, in the chair.

Lieut. A. Leeper, R.N., was elected a Fellow of the Society.

The following papers were read:—

(1) "A Few Meteorological Observations made on a Voyage up the Nile in February and March, 1885," by Dr. W. Marcet, F.R.S. The author on a voyaye up the Nile from Cairo to Assouan made a series of meteorological observations, and in the present paper gives the results of those relating mainly to nocturnal radiation, and the temperature of the water of the Nile.

(2) "The Mean Direction of Cirrus Clouds over Europe," by Dr. H. H. Hildebrandsson, Hon. Mem. R. Met. Soc. The author has collected a number of observations on the movements of cirrus clouds over various parts of Europe, and after discussing them has arrived at the following results:— (1) the mean direction at all stations lies between south-west and north-west; (2) in winter the cirri come from a more northerly direction, and in summer from a more southerly; (3) in winter the northerly component is greater on the Baltic and the North Coast of the Mediterranean; (4) the mean directions of the upper currents nearly coincide with the mean tracks of storm-centres; (5) the upper currents of the atmosphere tend in general to flow away from those areas in which a barometrical depression exists at the earth's surface, towards those in which there is an elevation of pressure.

(3) "On the Influence of Accumulations of Snow on Climate," by Dr. A. Woeikoff, Hon. Mem. R. Met. Soc.

(4) "Note on the Weather of January, 1881," by Mr. E. Harding, F. R. Met. Soc. It will be remembered that the weather of January, 1881, was remarkable for the prolonged and exceptionally severe frost, the heavy gale of the 18th and 19th, and the snowstorms. The author has prepared isobaric charts for the North Atlantic and adjacent continents for January, 1881, and compared it with similar charts for January in other years. He shows that the severe weather in 1881 was due to a reversal of the normal conditions, the atmospheric pressure being high in the north and low in the south.

(5) "Results of Meteorological Observations made in the Solomon Group, 1882-84," by Lieut. A. Leeper, R.N.

(6) "Graphic Hygrometrical Table," by Mr. D. Cunningham, M.Inst. C.E., F.R Met.Soc.

**A New Hair Dye.**—A very recent hair dye, and one which is said to be good, is made by dissolving freshly-prepared ammonia-tartrate of bismuth, or the ordinary scale citrate of bismuth and ammonia, in weak glycerine, and mixing this with a solution of hyposulphite of sodium in glycerine and water, and finally diluting with more water.

THE New York *Industrial America*, in commenting on English and American made axes, says the real reason that the latter is preferred by colonists and others is on account of the superior shape. "Its refinements of form are not easily copied. The handle is one of the most perfect pieces of work human ingenuity has produced, and it seems strange that it has not been carefully copied by means of the ordinary copying lathe."

# SCIENTIFIC NEWS.

THE jubilee meeting of the Statistical Society was held this week, and was attended by a number of representatives from foreign countries. Sir R. Rawson, the president, claimed that "statistics might be defined as the science which treats of the structure of human society," and undoubtedly they do form a very valuable branch of knowledge. As M. A. De Foville pointed out, however, "ignorance, passion, and unscrupulousness render an instrument of truth the vehicle for the dissemination of error." Dishonest and unscrupulous statisticians are the worst enemies of statistics; and it is well, therefore, that there is a society in which statistics, which form the bases of arguments, can be calmly examined by a dispassionate body of experts.

At the recent annual general meeting of the Marine Biological Association, the report which was read stated that nearly 300 persons had already joined, and that a sum of over £8,000 had been collected or had been promised. The expenses for the year amounted to only £263. Prof. Moseley and Mr. Crisp spoke warmly of the services rendered by Prof. Ray Lankester, especially in pushing on the work of establishing the laboratory at Plymouth. The scheme has now been taken up at Oxford, and we may hope that it will in a short time become a flourishing institution.

The Astronomische Gesellschaft will be held at Geneva on August 19—22, Prof. Auwers, president, and Profs. Schönfield and Seeliger, secretaries.

Part VIII., Vol. III. of the *Journal* of the Liverpool Astronomical Society contains a variety of interesting papers, several illustrations, and the index to the volume. The annual meeting for the election of officers and council will be held on July 25.

The eighth annual report of the Hackney Microscopical Society shows that, although the finances are in a not altogether satisfactory condition, owing to a non-observance of Rule I. by a considerable number of members, the society is progressing with its work, and attracting notes and papers of considerable interest. The report contains, amongst others, a valuable paper on the Hackney Brook, by Mr. J. Greenhill.

The Cutlers' Company of Sheffield will hold in July, in the Cutlers' Hall, an exhibition of handicraft work carried on within the jurisdiction of the company during the present year. The exhibition will show samples of all stages of manufacture of hardware and metal goods, cutlery taking a very prominent part, and will contain also a loan exhibition of the finest specimens of old metalwork that can be got together for the purpose, and a loan collection of old silver of great value. The applications by exhibitors already exceed 1,400.

The International Industrial and Commercial Congress will be opened on the 16th of August at Brussels, where technical questions and those relating to work and to Industrial property will be discussed. The Congress will then be transferred to Antwerp for the consideration of economical, commercial, and geographical subjects.

The most remarkable ride ever accomplished on a bicycle was completed on June 19, when Mr. H. R. Goodwin, of the North Manchester B.C., reached London from Land's End, and made a record of 2,050 miles in 19 days. Leaving Land's End on June 1, he reached John o' Groats in 7½ days, and arrived at the starting point again in less than 16 days. Thence he rode up to London, and arrived as stated on the 19th, feeling fresh and well. Mr. Goodwin rode a 40in. "Facile," a machine which long ago established its claim to be a first-class and safe roadster.

The *Engineer* says:—Complaints are constantly being made by passengers using the Great Northern trains running on the Metropolitan Extension of the London, Chatham, and Dover Railway. They complain of being forcibly thrown from the carriages as they are stepping to the platform by the sudden recoil of the brakes. A considerable period elapses between the stoppage of the train and this recoil, and hence even the most careful passengers are liable to be thrown as they step from the footboard. Several passengers have been thrown in this way, and insult is then added to injury by their being told to be more careful.

At a public meeting convened last Saturday by the Royal Academy of Music, and presided over by Sir G. Macfarren, it was resolved "that it is desirable to fix a standard for musical pitch throughout the United Kingdom which may accord with that of other countries"; and "that steps be at once taken for securing the adoption of the standard pitch in the principal orchestras; and also, if practicable, by the regimental and other bands of the British Army. Another resolution appointed a committee to carry out the previous resolutions, the following being requested to serve:—Mr. R. H. M. Bosanquet, Mr. A. J. Ellis, Mr. Hipkins, Dr. Pole, Dr. W. H. Stone. Mr. Walter Bache, Mr. Otto Goldschmidt, Mr. Henry Holmes, Dr. Hopkins, Sir G. A. Macfarren, Mr. Walter Macfarren, Mr. Patey, Mr. Sims Reeves, Mr. Sainton, Mr. Santley, Dr. Stainer, Mr. Van Biene, Mr. A. C. White, Mr. Bruzaud, Mr. Blakeley, Mr. Willis, and Mr. Brinsmead. If organs are to be brought to the new standard pitch there will be plenty of work for builders, even if it is only in shifting the pipes to lower the pitch. As to bands, the cost of new instruments will be a great obstacle.

News has been received that the German expedition in Eastern Africa has failed completely, Dr. Böhm having died at Mua in the end of March, last year. His companion, Herr Reichard, is safe at Karema, but all the collections have been lost.

The Mexican Government have resolved on undertaking a geological survey of the whole country, as far as practicable, and they have assigned 10,000 dollars for the preliminary expenses. Such a survey will be of the greatest importance to all the mining districts of Mexico.

Writing in the *Bulletin Société Chimique* on the action of bacteria on albuminoids, M. A. Gautier says that the poisonous alkaloids produced seem to be identical with those generally known as ptomaines. He proposes that, as they are constant and necessary principles in the normal excretions of living organisms, and have been detected in the saliva, urine, muscular juices, sweat, and also in numerous glands, they should be called "leucomaines." They are mostly poisonous, crystalline, and give crystalline platino-chlorides.

It is stated that Dr. Riebeck will next autumn commence a second voyage round the world. He will visit North America, the West Indies, South America as far as Magellan's Straits, the West Coast of America, the Sandwich Islands, Australia, the islands of the Pacific, and Eastern Africa. Dr. Von den Steinen, who has only recently returned from an important exploration in South America, will accompany him.

According to M. Witz, the proportion of ozone in the atmosphere of Paris last year was in inverse ratio to the mortality from cholera.

**Selenium Sunlight Measurer.**—M. Morize, of Rio de Janeiro, has invented an ingenious selenium apparatus for measuring the relative intensities of the rays of the sun at different altitudes above the horizon. It consists of a selenium cylinder prepared according to the plan of Professor Graham Bell, 38 discs of copper being insulated from each other by smaller mica discs, and the edges filled in with selenium. It is insulated by glass supports inside a glass envelope, from which the air has been exhausted. The vessel is elevated in a place where surface reflection does not reach it, and the axis is placed parallel to the axis of the earth, so that the rays of the sun fall normally on the selenium cell, and illuminate the same surface. Its position can be altered to keep up this condition from day to day. A constant current traverses the selenium and a galvanometer in circuit with it.

**Koumiss.**—The following is said to be a good recipe for the preparation of koumiss: Powdered sugar of milk, 100 parts; glucose (prepared from starch), 100; cane sugar, 300; bicarbonate of potassium, 36; common salt, 33. Dissolve these ingredients into 600 parts of boiling fresh whey of milk, allow the solution to cool, then add 100 parts of rectified spirits, and afterwards 100 parts of strained fresh beer yeast. Stir the mixture well, and put into half pint bottles. The bottles must be well corked and kept in a cool place. For the preparation of koumiss add five to six tablespoonfuls of this extract to a quart of skimmed, lukewarm milk, contained in a bottle of thick glass, cork well, keep the bottle for half a day in a moderately warm room, and afterwards in a cool cellar, shaking occasionally.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. Passmore Edwards.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

> **"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."**
> —*Montaigne's Essays.*

## 16 CYGNI AND PAIR IN FIELD—$\alpha^1$ CANCRI—$\alpha$ DRACONIS—53 OPHIUCHI AND STARS IN FIELD—M 53 COMÆ—THE LATE PREBENDARY WEBB—16 COMÆ—OPTICAL.

[24390.]—In mentioning the fact that in the immediate neighbourhood of the wide pair formed by 48 Cygni and P XX. 243, there are "two similar but smaller pairs," Prebendary Webb says: "The student will meet with many inexplicable arrangements of this character in crowded fields." In speaking of 16 Cygni, Mr. Webb makes no mention of the circumstance that there is a pair in the field which to a considerable extent illustrates the truth of the remark quoted. 16 Cygni is itself a beautiful object. I observed it for the first time on the 17th September last, with 45 in my 3¼in. (o.g. by Wray). Both stars were yellowish, but B was noticed to be dusky. A was found to be 0·2 mag. above B. The pair in field referred to above was observed, and noted in these words: "An exactly similar, but fainter, pair in field, *following*." On the 21st I saw 16 Cygni again, and confirmed these observations. On November 27th I made another observation. Both seemed pale gold, but B somewhat dusky in comparison with A. A was a little brighter than B. The pair in field was again observed, and the *f.* star was found to be the brighter. From "Celestial Objects" we find that the difference between the components of 16 Cygni was found by Struve to be 0·2 mag.; but that the difference between them, according to Smyth, is half a magnitude. A suspicion might therefore arise that one of the stars, probably the smaller, is variable; but from the observations given in "Celestial Objects" by Mr. Webb himself and by Mr. Franks, it is evident that the relative brightness of the components has been for a long time the same as it was found to be by Struve, and it will be noticed that the observations given above show that the difference between the stars last year was just the same as what Struve found. Perhaps Mr. Sadler will say whether or not *both* the magnitudes given by Smyth are taken from Piazzi, or whether the magnitude of B was estimated by Smyth himself.

*$\alpha^1$ and $\alpha^2$ Cancri.*—I think I can clear up Mr. Holmes's difficulty. The star called "α Cancri" in the appendix to "Celestial Objects" *is* $\alpha^2$; but Mr. Webb seems to have omitted the small "²." I presume the small "²" has been omitted because the star is simply called "α" in Proctor's "Atlas." $\alpha^1$ is commonly known as "60 Cancri," and is so marked in Proctor. 60 Cancri is β 212; and it is 275 in Mr. Gore's recently issued and most valuable "Catalogue of Suspected Variable Stars." There seems some reason for believing it variable; for while the *D.M.* mag. is 5·8, Webb and Birmingham both found it 8 mag. In 1877 and 1878 Mr. Gore found it equal to 45 Cancri (which was the same brightness as that which Sir Wm. Herschel had found it to have); but in 1883 he found it to be "two steps less than 45." The colour given by Birmingham was "pale orange red." I observed it twice within the last few months for colour; but although I did not estimate or record its mag., I may say safely, I think, that it was not fainter than 6 mag. On Jan. 11, I called it "light orange," and on February 9th "orange."

*α Draconis.*—Under this star, Mr. Gore, in his work referred to above, quotes this from Smyth: "I have had this in view many times, and always looking like a small third, though Baron de Zach but shortly before classed it 2·3." Could Mr. Gore or Mr. Sadler give me Smyth's authority for this statement, and any additional information concerning Baron de Zach's observation referred to? If de Zach was right, the star must have brightened very appreciably after the epoch of Pigott's observation.

In describing M. 53 Comæ, Prebendary Webb says, "Not very bright, $3\frac{7}{10}$in." I was much surprised in examining this object, for the first time, recently, to find that this description could not be considered applicable, but that the cluster was both bright and beautiful, even although the aperture (3¼in.) I employ is less than the aperture of Mr. Webb's telescope. My first observation of it was obtained on the 10th May. I used powers of 45 and 145. I entered, "Large and splendid; like a comet; and with blazing centre. It is difficult to understand how Mr. Webb could say, 'Not very bright $3\frac{7}{10}$in.' Brighter and larger than M 94, Can. Ven., with which it was compared. It forms an isosceles triangle with two small stars." Conditions on this occasion were not at all good. On the 14th it was "quite plain; bright," despite the fact that dawn was commencing, and the sky hazy. On the 17th I wrote, "Bright; though it did not seem quite so bright as before." The sky was beginning to brighten, and definition was poor.

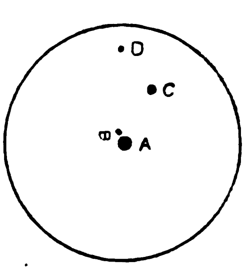
Since writing the preceding, I have learnt the heavy loss astronomy has sustained in the death of Prebendary Webb. I am sure all will heartily agree with what "F.R.A.S." says on p. 300. No one, probably, has done so much for amateur astronomers, even in England—where astronomical research has been so much and so successfully prosecuted by amateurs. He was, too, an astronomer in the truest sense of the word. Everything he wrote showed how unaffected was his pleasure in his favourite pursuit, and showed also how fully he realised the true nature and object of that pursuit. The most apparently trivial detail and circumstance has its beauty and its value for him; he rejects nothing as insignificant; yet he never subordinates the end, the attainment of a realisation of the constitution and mechanism of the universe, to the means, the registration and discussion of the detailed facts. I think that herein, and in the feeling of the vastness, the unity, the mystery, and the beauty of the heavens, which pervades his work, lay the secret of much of its influence. Of course, the detailed facts of the science, and its technicalities of detail and expression, are essential, are the indispensable material out of which it is to be built up; but they are not the science itself, and it was Mr. Webb's good fortune so clearly to recognise their true importance as to accord them their full value and their proper place, neither depreciated nor exaggerated, in the vast and matchless structure of the science.

On p. 280 of "Celestial Objects" it is said, concerning 12 Comæ, that it is "1½° *s.p.* 16, the 'lucida' of the constellation." Upon what authority does this statement that 16 Comæ is the "lucida" of Coma Berenices stand? For whether we include in the name "Coma Berenices," the whole constellation, or restrict it to the lovely asterism from which the group derives its name, 16 Comæ certainly cannot be called the "lucida" now. Argelander makes β Comæ mag. 4, and the brightest star in the constellation. Heis makes β and γ the brightest stars, making them equal, and the mag. 4 – 5. Argelander and Heis agree in their estimates of 16 Comæ, making it mag. 5. So far as the results of my own observations go, γ is the "lucida" of the group itself. On May 18, 1884, I made it, with opera-glass, 4·5, and called it, with 45 on 3¼in., "ruddy orange." The next evening I estimated it again, and made it 4·6. On June 18 I made the following sequence and estimates of colour. I used γ Comæ as the standard at 4·5. The mags. in the last two columns of the following table are Mr. Espin's, and are taken from the L. A. S. *Proceedings* II. page 65.

| Star. | Mag. | Colour. | Arg. | Heis. | Acti-nic. | Opera glass. |
|---|---|---|---|---|---|---|
| Comæ | | | | | | |
| 14 | 5–1 | Reddish cast | 5–4 | 5 | 5·05 | — |
| 16 | 4·9 | — | 5 | 5 | 4·95 | 4·90 |
| 13 | 5·1 | Yellowish | 5 | 5–6 | 5·00 | 5·30 |
| 12 | 5·0 | Pale yel. or pale orange | 5 | 5 | 5·00 | 4·90 |
| 17 | 4·9 | Yelsh. white | 5 | 5–6 | 4·80 | 4·80 |
| 21 | 5·2 | — | — | — | 5·20 | 5·50 |
| 18 | 5·5 | — | — | — | 5·52 | 5·60 |

The magnitudes of 21 and 18, according to Arg. and Heis, are not given in Bazley's "Stars in their Courses," from the table in which I have taken these comparative estimates. Just now I have not access to any other authority. If, therefore, 16 Comæ was ever the brightest member of this beautiful group, it must surely be variable, unless, indeed, γ Comæ has increased in brightness. γ is 15 Comæ, and is β 279. It is called by Schmidt "deep golden yellow." Its mag. in "D. M." is 4·7.

*53 Ophiuchi and Stars in Field.*—53 Ophiuchi is an exceedingly pretty object. There seems to be some difference about the colour of A. Smyth's colours are "greyish; pale blue"; but Webb adds —"Dawes, 6, light yellow, so Franks 1876." In a valuable letter in "Ours," for Nov. 18, 1881, entitled "Star Gazing," Messrs. Read and Sadler, say: "A, pale yellow; B, pale blue." They add: "According to Smyth there are two 8 mag. stars following, the south one of which seemed very much fainter than the other, which was almost equal to the *comes* to 53." They used a 6½in. Calver. In a letter in the succeeding number, Mr. A. Stanley Williams gives the colour as "pale yellow, bluish," in 1880, with 5¼in. Calver. I have obtained several observations of this star, which are given below. I suppose that Smyth's 8 mag. stars are the two stars lying *s.f.* in field, and marked C and D in the following diagram. It will be noticed that while my observations of the colour of A agree with the majority of those given above, I have always observed B to be either "lilac" or "purple."



| Date | A | B | Power |
|---|---|---|---|
| 1883, July 17 | Light Yellow | Lilac. Assuming A at 5·6 (Σ.'s mag.), estimated B at 7·4. | 145 |
| „ „ 27 | Light Yellow | Purple | 145 |
| „ Aug. 3 | Yellow | Purple 8·0 ± | 145 |
| 1884, Aug. 29 | Pale Yellow | Lilac | 45 |
| | Of the two stars *s.f.* the northern one is much the brighter. | | |
| „ Sept. 13 | The two stars *s f.* are certainly not *both* 8 mag. The N. one is distinctly brighter than the *comes* to 53, and the *south* one is distinctly fainter than the *comes*. | | 145 |
| „ Oct. 15 | Many stars in field. The two nearest *s f.* are very unequal in mag.—the N. one 7 mag., or so; the S. one, not more than 9. | | 45 |
| 1885, June 8 | C is certainly above the *comes* to 53, and D as certainly below it. There is at least 1½ mag. between C and D. | | 45 |
| „ „ 9 | Light yellow. | Lilac. | 145 |
| | Confirmed last night's observations of C and D. | | |

Perhaps Mr. Sadler, "F.R.A.S.," or some other astronomical correspondent, can give further information about these stars.

With reference to what Mr. Sadler says on p. 276, concerning the dividing by Dawes of η Coronæ with a 3⅜in. when the distance was only 0·88, I would like to ask if Dawe's formula was not intended to apply to *six-magnitude pairs*, and whether the circumstance that both the components of η Coronæ are brighter than the sixth magnitude may not have a bearing upon the matter? I would also like to ask whether the distance Mr. Sadler names (0·88″) is an actual measure, or was obtained by calculation—and if the latter, whether the theory of η Coronæ is so thoroughly understood that calculation based upon it may be relied upon implicitly?

Upon p. 277, "Beta" says, speaking of the telescope employed by "F.R.A.S.," "His o.g., however, is probably no larger than mine; for although I called my telescope a 4in. for brevity, it has a *clear aperture* of that diameter, and the o.g. must, therefore, be about 4⅛in." I would like to inquire concerning this remark, whether it is not founded on a misconception. Is it not the case that the "aperture" assigned to a telescope is almost invariably the "clear aperture"? I presume, for instance, that when "F.R.A.S." says that his telescope is "a 4⅛in. Dallmeyer," he means that its clear working aperture is 4⅛in., not that its total aperture is 4⅛in., and that, therefore, its clear aperture is something less. If this be so, "Beta's" criticism must be founded on a mistake.

Glasgow. **S. Maitland Baird Gemmill.**

## B. 607.

[24391.]—This red star, which is No. 683 of my catalogue of suspected variables, seems worthy of further attention. It was rated 5m. by Heis, and was measured 4·67 at Harvard (H P. 3935), but was estimated only 7·5 by Burton in 1876. A remark of Sir W. Herschel's in the *Philosophical Transactions* for 1873, evidently refers to this star. He says: "Near Lacerta's tail-end is a star of between the 4th and 5th magnitudes, not mentioned in Flamsteed's catalogue, though the 1st Lacertæ, not far from that place, is recorded. It is so easy to be seen with the naked eye, and in a spot where but few of that magnitude are near, that we can hardly account for its being omitted if it had been visible to Fl. Its colour is pale red." This remark of Herschel's seems strongly in favour of variability, as it shows that the star was probably faint at the date of Flamsteed's observations. The star is identical with 7765 B. A. C., and lies about 2° north of 1 Lacertæ. **J. E. Gore.**

Ballysodare, co. Sligo, June 20.

### THE CASSEGRAIN.

[24392.]—It seems fruitless to appeal to the mathematicians. Neither Mr. Wassell's letter nor my own has elicited the slightest response, or, I presume, the problem is too hard a one even for Cambridge wranglers.

I think Mr. Edmunds's letter comes very apropos, for, speaking of such mathematicians as I have met, I have found that, though familiar with all the intricacies of the higher branches of the subject, they seemed quite unable to apply their formulæ and deductions to any practical use.

Thus I do not doubt that amongst the readers of the "E. M." are many who have given much attention to optics as a theoretical subject, yet are quite unable to work out this question of the curves for a Cassegrain or a Gregorian. Even our talented correspondent "Orderic Vital," though thoroughly at home in every point of the theory of the achromatic object-glass, has shown himself unwilling to tackle that of the compound reflector. Dr. Royston Pigott, too, having made a beginning, seems to have broken down halfway. Will *no* one come to the rescue? **A. S. L.**

### HIGH-POWER OPERA AND FIELD-GLASSES (AND BINOCULAR TELESCOPES).

[24393.]—On return from a visit to Paris, I availed of the invitation contained in the trade advertisements inserted in the "E M 's" of 5th and 12th June, to compare the so-called English instruments—the result of 30 years' experience—with the new French-made high-power glasses.

I found an excellent, clear, large field glass, power 6, price, in aluminium, 11 guineas, which compares with the small field rather lighter French glass, power 7, price, in aluminium, £4 2s. I also found a very good smaller glass, power 5, price £5 in brass, which compares with the rather smaller French instrument, power 4, price £2 10s. in aluminium. There was, of course, nothing to approach the 10 power at any price.

I should warn your readers against the remarks of "Experience" (letter 24285, p. 279), and G. R. Baker (letter 24318, p. 302), in so far as they suggest that high power means necessarily loss of light, and that the binocular telescope may compete with the 10-power French Galilean glass.

I saw in Paris a beautiful specimen of the 15in. binocular telescope, power 22, price £12 in aluminium; but the French makers admitted that it was useless after dark. To make perfectly sure, however, three days ago I took to the Albert Hall a 10-power French glass and a new 14½in. binocular telescope which a friend had just purchased of the house now trading in the name of Ross for £18, in aluminium. At 5 p.m., by daylight, the 22-power telescope could not distinguish a person's features at the opposite end of the hall, for want of light. By night it could show nothing at all; whilst the 10-power showed everything perfectly by day and night equally well.

Excellent as the binocular telescopes now are, and delightful as they are for telescopic use in the open with plenty of light, they are not to be mentioned in the same day with the high-power Galilean glass for general use. The four-lens eyepiece is fatal to them on the ground of absorption of the light.

There appears to be some desire to attempt to persuade the public—as an apology for low powers—that (as G. R. Baker expresses it) "glasses are required primarily to give *extensive* views of landscapes or groups on a stage," forgetting that whilst there is no possible excuse for such a statement when it comes to be examined, there is, on the contrary, every reason why, with very rare exceptions, a magnifying glass should magnify as much as it can be made to do without losing light. When once the public learns that high powers can be had, the determination to possess them is universal. One of our readers wrote from San Francisco for them: he was in the trade, and understood it well. Another was a Royal Engineer in the Afghan Boundary Camp at Quetta, who wrote he would gladly sacrifice some field for more power, as they had no glass over four power in all the camp!

On inquiring how a glass might be forwarded to Quetta, I learnt that 16 glasses were going out that week, and that the benighted War Office authorities had ordered them of four-power only, again. The Paris maker told me last week that the Russians had taken all the high-power glasses he had offered them, including the ten-power models.

It still remains to arrange for the supply in London. Necessarily disgusted at the treatment which G. Dickson and others received (24284, page 279), I would gladly act on the Editor's very natural suggestion following that paragraph.

**Montmartre.**

### AUTOMATIC MUSICAL INSTRUMENTS.

[24394.]—Replying to the letter of Thomas Pugh (page 348), I should say his valour has outrun his discretion in attempting so large an instrument, more especially as he has constructed it on the principle of using the paper itself as the valve, which requires a much wider band than when the paper serves only as a stencil.

On the latter system the width of the perforations would not exceed ⅜in., and the spaces between might be the same, thus making the "gauge" ¾in. centre to centre of holes. Allowing for margins, this would bring the five octaves within a width of 23in. instead of 41in. as at present.

In order to get the levers this distance apart, it will be necessary to rearrange the windchest, and put the lower reeds alternately in two rows, so as to get the channels and pallets of sufficient width; the higher notes can be got into the ¾in. space. Mr. G. Fryer has again and again promised, and equally often broken his promise, to send a sketch of the mechanism of the "Organette," which I think is somewhat simpler than that of the "Organina" described by myself; but either of them would serve as a model for Mr. Pugh to work from in altering his instrument to the stencil-plate principle.

Mr. Wenham's tune-bands are only 9in. wide; but all such instruments as the "Pianista" are very complex and delicate, and require greater accuracy of workmanship than such as the "Organette" or "Organina." If, however, Mr. Pugh likes to try his hand at one, there is a drawing of it in one of the "E. M.'s" of a year or two back.

The "Cabinetto," notwithstanding its high price, only contains, I think, 16 or 17 reeds, and an imperfect scale to which all the tunes have to be adapted.

Mr. Pugh's roll of 600ft. rather takes one's breath away. Has he estimated the labour of punching the holes, and the length of time it will take to "grind" such a length through the instrument? **A. S. L.**

### NITROBENZOLE FOR ENTOMOLOGISTS.

[24395.]—Most insect collectors have some pet poison wherewith to shorten the lives of those insects which, like the Lepidoptera, are given to knocking off their delicate scales if allowed to live.

Prussic acid, or to speak more exactly, potassium cyanide, under a stratum of plaster of Paris is very efficacious and cleanly, and in careful hands is all that can be desired; still, the cyanide is a fearful poison, and young people (and many of our insect collectors are very young people) are apt to be careless.

I have found that a plug of plaster of Paris at the bottom of the "killing bottle," if saturated with nitrobenzole, is quite as efficacious as when prepared with potassium cyanide, while the nitrobenzole is not a dangerous poison.

**S. Bottone.**

### THE CALORIE OR FRENCH THERMAL UNIT.

[24396.]—"Tubal Kain" (letter 24191) was certainly moved by a good intention when he wrote his lines on this subject, but although there is truth in them—to use his own expressions—"unless corrected, they will lead to serious errors." True, what he calls the *British* thermal unit, which ought to be called German, as Fahrenheit was a German, is one pound of water elevated in temperature 1° Fahr. True, also, the Centigrade thermal unit, which might be called Swedish, as Celsius, its creator, was a Swede—not a Frenchman—is one kilogramme of water elevated in temperature 1° Centigrade. True, again, that the division in 100 parts of the temperature, from melting ice to boiling water, represents 180° Fahr. Thus far, "Tubal Kain" is right; but he is wrong when he says that the degree Centigrade equals 1·80° Fahr. He certainly forgets that the two thermometers have not the same starting point. The zero Centigrade is at 32° Fahr. How, then, will he calculate the temperature in Centigrade degrees of, say, 16° Fahr., with the proportions of 1·80? Boiling point being 212° Fahr. is 100° Centigrade; 212, divided by 1·80, will give 117·7 instead of 100. 64° Fahr. = 17·7 Centigrade. If you multiply 17.7 by 1·80, you will find only 32·4. Blood-heat is 37° Centigrade, which × 1·80 = 66·60, instead of 99 Fahr. Text-books give several means of converting these degrees into one another.

**Ch. Rabache.**

### GLASS DISCS FOR SPECULA.

[24397.]—Mr. Wigmore, of Melbourne, appears to have overlooked the fact that I gave in these columns, a few volumes back, two or three addresses where the above might be obtained. I am quite sure he might safely intrust his order and cash to Messrs. Chance, of Birmingham. They supply properly annealed discs at a somewhat lower price than the Northern Plate Glass Company, of Newcastle-on-Tyne; but the cheapest source of any I know was a Mr. Scott, of Sunderland, a contributor to this paper. Unfortunately he has lately died, and I do not know whether they can now be obtained. These were cast with a concave curve, not perfectly regular, but it would save some labour in the rough grinding.

Messrs. Chance could supply you with an 18in. disc, 2½in. thick, cost £5 to £6; a 12in. disc, 2in. thick, would cost about 25s.; and a 9in. disc, 1½in. thick, about 10s. A 2½in. cube of glass (ordinary cast plate or crown quality) weighs 1lb. 7oz.; and from this you can easily calculate the weight of any size disc if you know the thickness. With a view to render you the most material assistance, I have written to Messrs. Chance, giving your name, address, and requirements, and asking them to write to you direct.

If I can obtain any further information, in a week or two I will write again to the "E.M.; but if you are desirous of losing no time, you might quite safely, I am sure, send Messrs. Chance a P.O O. for 30s. or £2, with the order for a 12in., and asking them to pay freight and insurance at their discretion, and send you the balance by letter. Let me advise not less than 2in. in thickness, and 2¼in. or 2½in. would be better. I am sure that we, on this side, will be glad to hear from you again.

Ramsgate. **J. C. L.**

### A NEW TELESCOPE FOR GREENWICH OBSERVATORY.

[24398.]—With reference to the letter of Mr. W. S. Franks, p. 347, and the remarks of "F. R. A. S." on p. 346, I presume those gentlemen are by this time aware that it has been decided to make a 28in. equatoreal for Greenwich, in accordance with the suggestions of the Astronomer Royal, which I append as taken from his report:—"The aperture of our largest refractor (12¾in.) is too small to allow of our observing successfully with the spectroscope any but the brightest stars, and though the Lassell reflector is somewhat more powerful, its mounting and clock-work are not adapted to carry a heavy spectroscope with the necessary steadiness and accuracy of motion. The firmness of the mounting of the South-east equatoreal and the perfection of its clock-work would make it peculiarly suitable for this class of work if it carried a much larger object-glass. After careful consideration of the conditions, I have satisfied myself that an object-glass of 28in. aperture and of 28ft. focal length could be mounted on the South-east equatoreal, in place of the present object-glass of less than half that aperture; and I have ascertained that Mr. Grubb would be prepared to undertake the construction of such an object-glass with a tube suited to the special requirements of the case, so that the telescope would be equally available for eye-observation or for use with the spectroscope. With Mr. Grubb's assistance, I have prepared a model showing how this may be arranged. While a large refractor is required specially for spectroscopic observations, it seems desirable also on other grounds that this Observatory should possess an equatorially mounted telescope comparable with those of other first-class observatories, so that we may no longer be prevented by deficient optical means from obtaining complete series of observations of comets and faint satellites."

I understand that it has been decided to carry out the suggestions above named, and that Mr. Grubb will at once set about the work. **S. B.**

### SAVAGES, WILD GRAIN, &c.

[24399.]—Having had exceptionally good opportunities of learning something about these degraded remnants—as some call them—I cannot help advising all who really desire to learn something about the past to study carefully E. B. Tylor's "Anthropology." It is wonderfully reliable on all matters hereto relating.

I have been now over 20 years alongside the Nogas, Singphus, Miris, Mishmis, Abors, Akas, and the first-class savage tribes that surround Asam, and among whom there are neither *coins, architecture*, nor *literary remains*, the usual sources of history; nevertheless, there are many clear proofs that the history of these races must extend back for an immense period, and that they have always been savages.

They are the remains of the races that once covered the *whole of India* ere the Aryan invasion, somewhere about 3,000 B C., drove them right and left to the hills, and amalgamated with some to form the Sudra out-caste staple of the people. The names given by these "Pre-Aryans" to the rivers are thick all over the maps, and customs that show a common origin, in the far past, are seen among races whose languages are now quite differentiated, except in numerals and such, which seldom change.

One singular custom common to all these Hill races, illustrates the original sexual liberty that existed ere marriage by capture gave a man right of private property in a woman.

The boys and big lads and single men have to sleep in large houses away from their parents, and also the girls in other houses, and I may say that *morality begins with marriage*. They see no harm in it, and when married are far more faithful than so-called "civilised nations."

I have got the history in outline of one group of tribes back to about the year A.D. 1400. The languages of all are monosyllabic and limited; we know as little about *them* as they know about us; they read nature like a book, where *we* are blind, and fatten where we should starve. Comparative philology and anthropology will eventually show who they are, and where from. They seem a mixture of the yellow Chinese, on one hand, and the Dyak (Malayan) on the other; developed slowly all over Southern Asia.

The vast amount of valuable information that lies buried here as to the past, people have no *conception* of, nor have anthropologists even, and few men here bother their heads about it.

As to wild grain, and its survival in a state of nature, we have here some five or six allies of rice alone, as common grasses. Surely those who consider the grains, vegetables, and animals we now use as specially created for us, forget that hundreds that are now useless may yet be indispensable. All nature is before us, if we only knew how to use it—animals, vegetables, and minerals.

The day may not be far distant when posterity will pity our practice of getting food from the present *natural* sources: it may be made synthetically. As it is, our loaves do not grow on trees, nor is sugar found like sand; compared to savages, our food is already highly artificial, and proof of *progress*.

**S. E. Peal.**

## TEST FOR PLATINUM.

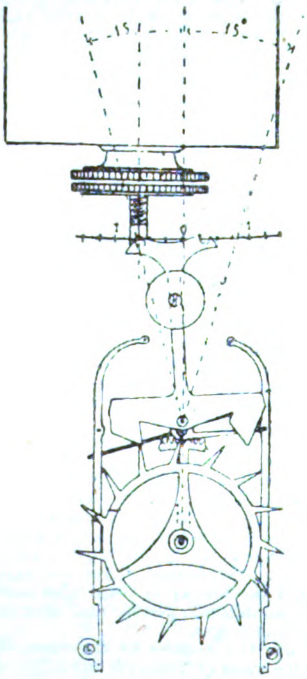
[24400.]—While analysing a mixture of salts a few days ago, I came across a very delicate test for platinum, which may be of interest to your readers. If to a very dilute solution of platinic chloride, a little potassium iodide solution is added, a rose-red colour is observed, which deepens in shade on standing. In stronger solutions the KI gives a deep red, almost black colour. If hydric sulphide be now added, the red is bleached, turned brown, or changed into a brown precipitate, according to the strength of the solution.

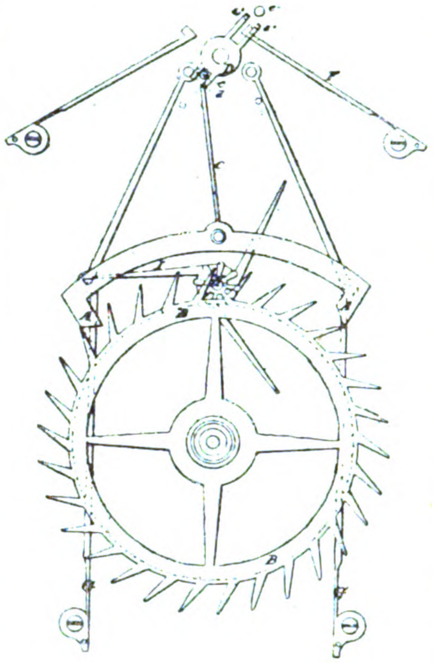
The red colour appears to be due to the formation of potassium iodo-platinate.

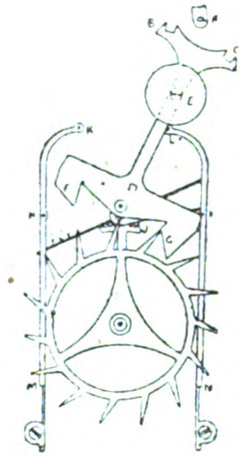
**C. Dampier Whetham.**

## HART'S PENDULUM ESCAPEMENT.

[24401.]—What does Mr. Hart, whose escapement you illustrate on p. 320, No. 1055, claim as the distinguishing novelty of his invention? As far as giving impulse at the bottom of the pendulum goes, Breguet did this in 1796 or 1798 (see *La Revue Chronometrique*, Vol. VI. p. 92, or the *Horological Journal*, Vol. XX. p. 4). And there are many other arrangements for giving effect to the same idea. As regards using a lever escapement for maintaining the vibrations, I have shown that method in conjunction with a remontoir (Fig. 11, *e* is the pin on pendulum rod), in my specification 191, A.D. 1877, of which I inclose a copy. I also send another arrangement of the same invention, which I designed some years ago. The nine figures trace the escapement through a whole vibration of the pendulum and back; but perhaps 1 and 5 will be sufficient to show the idea.







A is a pin in the bottom of the pendulum rod. There are dangers and difficulties attending this method of giving impulse to a pendulum.

84, Strand, June 17. **H. M. Frodsham.**

## CRANK AXLES.

[24402.]—I see (p. 345) that the Leicester railway servants are still for *iron* axles. The resolution of a meeting of drivers and servants is one that must be important, as they are the men who know the working part.

Messrs. Linney and Lawson's way of making cranks with all the fibres in the proper direction seems very good indeed. Might I ask them if they find trouble in making sound welds?

Perhaps Mr. Casebourne (p. 349) would give some more figures from his diary to show if the fractures were in the inside or the outside webs? Is it found that the axles last longer with two or four bearings? How many square inches of section are there in a web, and in a crank-pin? And if the strength is, say, 27 tons per inch, what ought the total breaking strain to be? Do your readers think the size of piston, stroke, and diameter of wheels has very much to do with the matter? Also, with regard to keys, do keys outside give any assistance to the crank and other axles? These are some of the matters that suggest themselves to an

**Engine-Driver.**

[24403.]—In reply to "Original Lockstitch," in your impression of the 5th inst. (let. 24321), I would remark that he seems to be surprised at the statement made by a correspondent that "Crank axles mostly break across the webs"; but I contend that statistics fully bear out the truth of this statement. Then, with regard to the question of twisting the iron, in order to bring the throws at right angles, I may say that at all the several railway companies' works in the district I belong to, crank axles are made in that manner, and I do not know the railway company who dispense with twisting, although I have worked at the forge for the last 26 years.

I am much surprised at his statement that "In a properly-made crank there is no grain." Now, I argue that the process of welding-up and drawing-out the iron naturally brings the fibre to run in the direction of the length of the axle, and when the throw is cut out the metal is cut against the grain, and the fibre of the iron forming the webs runs crosswise, hence their frequent breakages.

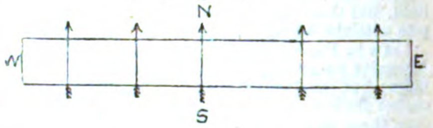
In the method of forging, illustrated in your last issue, the faults (in ordinary crank axles) caused by the direction of the fibre, and of being twisted, would appear to be overcome, if we may believe the patentees; but this remains to be practically tested. Perhaps other practical men would give their opinions upon this matter. **Wilfred.**

[24404.]—I have read with much interest the letters that have been written on this subject, and have been expecting every week to find some mention of "Saxby's method of testing for flaws in iron and steel." I would have sent this description before, but thought it might be "ancient history" to many. I do not know if this is the test referred to by "Iron Crank"; but anyhow I think it should not be overlooked. The following is extracted from Pepper's "Cyclopædic Science":—

"It is well known to engineers that it is a most difficult and often impossible thing to find out the existence of a false weld in a forging, or of a blow-hole or honeycomb in an iron or steel casting. Everyone knows that a simple method by which internal flaws and solutions of continuity in constructive details could be easily detected would be of enormous value to the world. Such a method has undoubtedly been discovered by Mr. S. M. Saxby, R.N., who has very judiciously been allowed by the Admiralty, during the course of this year, to experiment with it in the royal dockyards.

"It has been known for nearly a century and a half that when a bar or any mass of soft iron is placed in the position of the dipping needle, it is at once sensibly magnetic, the lower extremity being a north pole in our latitudes, and the upper extremity a south pole. The same action, only weakened, takes place in a bar hanging in a vertical or any other position; only the effect is weaker the more the position of the longitudinal axis of, for instance, a long bar departs from that of the magnetic dipping needle.

FIG 1



"When, therefore, as in Fig. 1, a small compass needle is slowly passed in front of a bar of very good iron, placed in an east and west direction, the needle will not be disturbed from its proper direction, which is of course at right angles to this, or north and south.

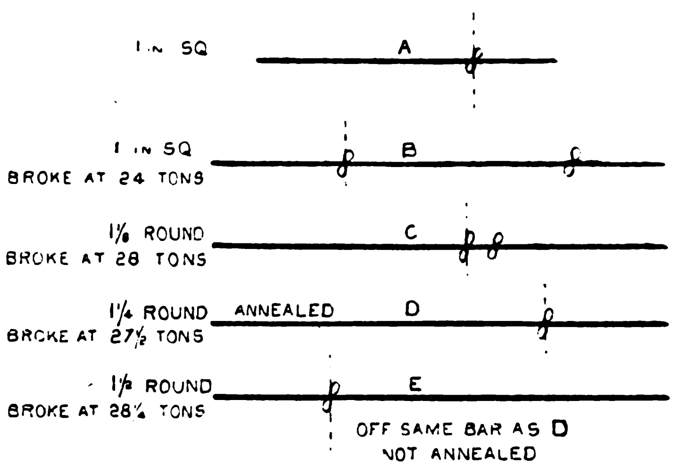
"All this refers to regularly homogeneous bars of best quality—to bars without any mechanical solutions of continuity. With internal flaws, or interruptions of continuity, the bar is no longer regularly magnetic. It has long been known that a good compass needle, or a good permanent magnet, must be homogeneous and without flaws, in order to take and retain its maximum amount of magnetism. In a word, *any mechanical solution of continuity is accompanied with a polar solution of continuity*, and the given bar or mass with flaws, whether permanently magnetised or temporarily so by the inductive action of the earth, is no longer one regular magnet, but several different magnets, with the different magnetisms separated from each other. The delicately-poised magnet of a compass can thus be made to tell the presence of such solutions of continuity.

FIG 2

⅝ ROUND 12" LONG

"Fig. 2 shows the actual results of the test with a ⅝in. bar 12in. long, and will illustrate the manner in which the compass magnet is affected by the pre-

FIG 3



sence of cracks, of solutions of continuity, in the bar, which is supposed to be lying in the equatorial magnetic plane, or east and west.

"Among the experiments which took place in the dockyards of Sheerness and Chatham were the following trials, conducted in the presence of the master smiths, the foremen of the testing houses, and several of the chief engineers of the Royal Navy.

"Mr. Saxby, for instance, was requested to find out the weakest spots in a number of bars, and to tie a string, or make a chalk mark, on each spot. Immediately afterwards all these bars were put into the testing machine and broken. Their history is given in Fig. 3. A scroll is placed where the weakest spot was found out by the needle. The vertical lines indicate the spots where the several bars broke.

"The smiths of the dockyards seem to have properly tested Mr. Saxby's powers in almost every possible way, and most ingenious devices were sometimes resorted to for the purpose. For example: In the centre of a bar of 1in. square forged iron was welded a piece of unmagnetised steel, about 5in. long. The needle detected a fault at about the centre of the piece of steel.

"Now, Mr. Saxby's method can detect the presence, and negatively, of course, the absence, of small or large solutions of continuity.

"It can detect false welds, smaller flaws caused by bad workmanship or wear, and, we believe, what is commonly termed 'crystallisation,' which will, probably, at once be generally acknowledged to consist in a disruption or parting of the facets of the amorphously arranged crystals of which iron is built up."

Such is "Saxby's test," as reported by Mr. Paget, C.E. As the space I have already occupied is so much, I will not offer any remarks of my own on the subject just now; but leave experts to say whether or not it can be applied to testiing railway crank axles. I believe it can.

**W. Rowland Hart.**

## SCREW THREADS.

[24405.]—The accompanying tracing is from a block of wood in which I have made seven cuts, all with the same cutter, but applied to the work in different ways. No. 1, 2, and 3 are horizontal cuts taken on the level or line of centres, No. 2 being an exact reproduction or counterpart of the cutter, which was itself placed in the axial plane of the work with its spindle vertical. In No. 1 the cutter spindle was inclined 10deg., and in No. 3 5deg. to the vertical. The other four cuts are all screws of 8in. rise in one turn.

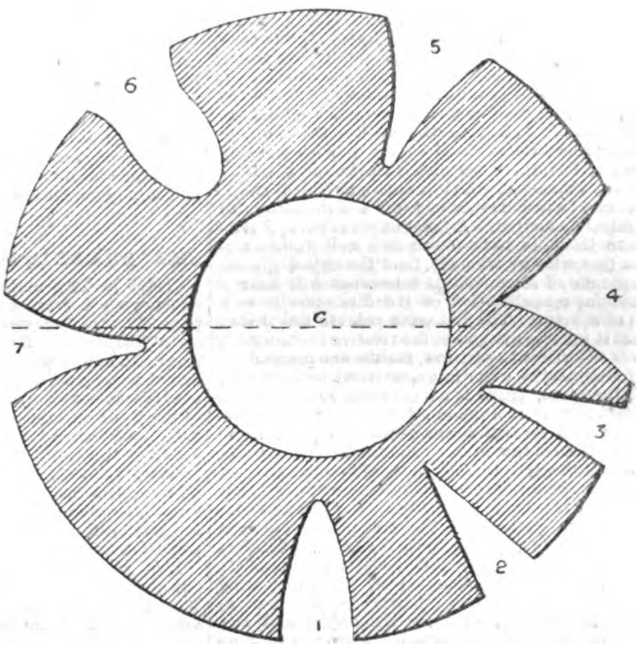
In No. 4 the cutter spindle is inclined 54° 46′, that being the angle of rise of the bottom of the thread, which is 5·65in. diameter, with a rise, as before stated, of 8in. per turn. In this case it will be observed that the acute angle of the tool leaves a sharply defined bottom to the groove, and that all the distortion occurs towards the top.

In No. 5 the spindle is inclined 45°, the mean diameter of the screw being 2·55in. with a circumference of 8in., and rise as before of 8in. Here the distortion is divided between the top and the bottom of the groove.

In No. 6 the inclination of the spindle is reduced to 37° 42′, that being the angle for a circumference of 10·35in. with rise as before of 8in. Here the great distortion occurs at the bottom of the groove.

No. 7 is a repetition of No. 5, as to angle of inclination of spindle; but with the plane of the cutter lowered so as to pass ⅛in. below the line or level of centres, which is indicated by the broken line L C. As the figure is a tracing from the flat end of the cylinder out of which the grooves are cut, Nos. 1, 2, and 3 alone show actual cross-sections of the respective grooves. The remaining four show greater widths with the same depth, as real cross-sections would do. I may remind the readers hereof that a real cross-section of such grooves is as impossible to represent in a drawing as it is to cover a globe with flat paper. I have been unable to send the specimen screw that I promised to the Editor's office, so I forward instead this tracing of another which will probably answer the purpose even better.

**J. K. P.**



---

[24406.]—I resuscitate my pen without much pleasure as regards the above subject, as it is once more its purpose to point out Dr. Edmunds's departures.

If Dr. E. would reflect upon or look up the history of deduction in Mechanics, he would be more chary of geometrical deduction even in statical questions. (24358), page 327, "The normal section is, as I have already shown, always a screw surface and never a plane. The base of the normal section is also always a screw line, and never an ellipse."

This is geometry pure and simple, and such normal section to a "bundle of spiral lines" has no theoretical or other use in any screw calculations.

Mechanical forces resolve themselves into straight lines, and with these straight lines and their vertical planes or "normal sections" have we alone to deal. The normal cross section of a screw thread for mechanical purposes is always cut by a plane and has always an elliptic base, and is never a screw-surface nor has ever a screw-line base.

The use of any normal section for calculation is remote. The "normal section" that assists a leading screw to resist torsion is the axial section, that being the one "normal" to the transverse stress from gear.

The value of its resistance is its area at one-third its height from base. A pure spiral, say of equilateral triangular section, would resist tension, compression, and shear in a plane normal or vertical to the tangent at about one-third the height from the base; for torsion, a tangent at about one half its height.

The only section needing regard in ordinary screws is the attachment surface to the shank; the stress on this section is on lines vertical to the tangent that bisects the vertical surface of the thread: only approximations can be got, but in fine-threaded screws the stress and breaking is practically simply longitudinal.

In an ideal screw and nut, the shear will take place on the attachment surface to the screw shank, the weakest place. That surface is about 6⅛ times the thread's height less in width than that of the nut, and at any point between the two attachment surfaces, both threads would have to be sheared, and they have a greater area than the shank surface.

**Vulcan.**

## LOOPED FIGURES BY GEARING.

[24407.]—I cannot but be pleased at the satisfactory results of "F. A. M.'s" experiments, and I think few will deny the beauty and symmetry of the designs transmitted to the English Mechanic. Very little credit is, however, due to me, as I did not myself invent this method of executing such work. All who were subscribers to the English Mechanic at the time will remember that I merely advocated the system originated by the late Mr. Gilray, whose lathe I described and illustrated; stating at the time, however, that in construction it was clumsy and ill made, owing chiefly to the fact that Mr. Gilray was not a very skilful mechanic, although a man of unusual ingenuity. I need not state that I was "written down," and the whole thing ignored or abused. "F. A. M.," however, took the matter into his hands, and has proved that I was perfectly correct in my estimation of this mode of originating looped and rose-engine patterns. The system is perfectly sound, and all that is needed to carry it out is accurate fitting of the apparatus, which Gilray was not capable of. It does away with the necessity of costly chucks, and the variety of figures obtainable is simply endless.

**O. J. L.**

## WHAT IS CREATION?

[24408.]—In letter (24365, p. 345), "F.R.A.S." propounds the above question, and asks me further "whether an Albino, born of normally constituted parents, is 'created,' and whether the same may be predicated of the descendants of salt-water mollusca, when their habitat becomes merely brackish, or vice versâ?"

I had thought that I had made my contention sufficiently clear in previous letters; but I will now try to make it more explicit!

In letter (24256, p. 257), I defined "creation" as the coming into existence of qualities, either physical or mental, which previously did not exist.

Does "F. R. A. S." take exception to this definition, or has he simply overlooked it?

Now, Darwin asserts that natural selection is daily and hourly at work, scanning animated or organic nature, to see where it can step in, rejecting some forms, selecting others! At the same time, he assures us that, unless new forms, which natural selection cannot account for, do appear, natural selection must remain inoperative.

It takes advantage of new and previously non-existent forms, only when they do appear; but it does not explain their appearance.

I hold that the appearance of such new and previously non-existent forms is due to "creation," which, necessarily, is at work as long as we have evidence of it, and I ask "F. R. A. S.," as I have asked evolutionists generally, how otherwise can the abrupt appearance of some new variety be explained?

I do not doubt that many qualities, physical as well as mental, morphological as well as physiological, may remain, through very many generations, latent and unexhibited; and that with a change of environment, these may appear to a greater or less degree, assisted sometimes by creation, in introducing a really new variety; but, in so far as the altered species is not absolutely non-pre-existent, it is attributable to heredity by reversion.

Albinos, and brackish-water varieties of mollusca descended from definite marine species, may be so explained.

In a recent letter, which the Editor had no room for, I illustrated the position by comparing natural selection to a steam-engine, the boiler of which was creation, without which it could not work; and tentatively, to elicit a definition of "evolution," I asked—"Is evolution a steam-engine which works without steam?" **H. B. F.**

## 100 TO THE INCH OF APERTURE.

[24409.]—It is surprising how tenaciously people will cling to a mere supposition if it is only bolstered up by the name of science. No doubt working hypotheses are useful—nay, almost indispensable—in grouping together isolated facts in the endeavour to formulate a coherent and intelligible whole which shall satisfy all the known phenomena. And, more than this, a sound theory ought to be able to indicate the regions where new facts are likely to be discovered. Used in this legitimate manner, there can be no possible objection to such working theories; but there are also theories of a totally different character, which do not explain a single fact, and which rest solely on a substratum of empirical deduction. A fair sample of such, I venture to think, is to be found in a well-known formula (invented by whom?) that the object-glasses or specula of astronomical telescopes will bear a maximum magnification of 100 diameters to each inch of aperture. The first weak point in this theory is that it ignores altogether the relative illuminating power of different apertures, for the one proceeds in arithmetical, the other in geometrical, progression, and, therefore, there is no constant ratio between the two factors. Suppose, for the sake of argument, that a 4in. will bear a power of 400 diameters under the most favourable conditions. Then a 2in. with half the power (200) has only one quarter of the light, and an 8in. with double power (800), has four times the light relatively. For the best conditions of vision there must be some balance between the two factors of illumination and amplification. Sir W. Herschel said, "Objects are viewed in their greatest perfection when, in penetrating space, the magnifying power is so low as only to be sufficient to show the object well, and when, in magnifying objects by way of examining them minutely, the space-penetrating, or illuminating power is no higher than what will suffice for the purpose, for in the use of either power the injudicious overcharge of the other will prove hurtful to perfect vision." ("Phil. Trans." Vol. XC. p. 81.)

It is well known that very small telescopes, say, of 2in. aperture and under, will not bear a power of 100 to the inch under any circumstances whatever; theoretically they should do, but practically they break down from want of light. On the other hand, some larger glasses will bear more than 100 to the inch. On several peculiarly favourable occasions I have used a power of about 700 diameters on a 5in. aperture without definition breaking down; but this limit has never been exceeded with the 11¼in., although the latter instrument is infinitely superior in penetrating and defining power.

According to the "Mensuræ Micrometricæ" the highest power employed by Struve in his great work appears to be about 800. Nor do I believe that on very large apertures much higher powers can be used to any advantage, the real limit to magnifying being, as most practical observers are painfully aware, the atmosphere. Local conditions do, undoubtedly, somewhat affect the ultimate result; but, go where we may, we cannot escape the disturbing effects of that great aërial sea through which we must necessarily view all celestial objects. Even the Italian and American skies, though eminently translucent, are not, so far as I can learn, much superior to our own in point of steadiness. Yet again, more can be seen with a low power on a large aperture than with a higher one on a smaller glass. Browning says, in his "Plea for Reflectors" (p. 34), that "when working with an 8½in. mirror, I generally used a power of 210; while latterly, using a 12¼ mirror of equally fine figure, I have nearly always had to observe with a power of 146. Yet with this I see much more than with the 8½, and power 210." Large apertures are certainly more sensitive to atmospheric disturbances; but a reducing stop can easily be applied when necessary, and the telescope will even then be more effective than a smaller instrument of the equivalent full aperture. But the value of large instruments does not depend upon any enormous magnification according to their inches of aperture. For instance, does any sane person believe that a power of 2,600 could be effectively used on the 26in. telescope at Washington? The experience of those astronomers who are in the habit of using great apertures would be, if published, an instructive commentary on the fallacy of the 100-to-the-inch hypothesis. Let it be distinctly understood, however, that I intend no disparagement of large apertures generally. On the contrary, I recognise fully their value and superiority for such objects as are beyond the reach of a moderate instrument. All I wish to point out is, that mere magnifying is a purely secondary question when compared with the increased penetrating and defining qualities possessed by a large aperture. Of course, it is the atmosphere which really is to blame for these discrepancies; but the atmosphere we have with us always, and any respectably consistent theory that deals with magnifying it (to an equal extent with a celestial object) ought surely to take cognisance of it as a modifying factor in the final result. Whether the lunar surface might afford such conditions as would irrefragably demonstrate the truth of this grand modern theory of magnification, I am not prepared to say; nor would I care to undertake a personal investigation, even with the assistance of the famous Jules Verne! All I can say is that my own limited experience on this planet leads me to think that the theory of 100 to the inch (except within exceedingly narrow bounds) is scarcely deserving of more respect than another well-known and much-abused formula which, from the log. of the aperture of any given telescope, deduces the minimum star magitude, to two places of decimals, that any given observer shall see with it?

**W. S. Franks.**

## THE BREAKING OF CRANK AXLES.

[24410.]—The method of testing iron bars to which your correspondent "Iron Crank" refers, page 349, was discovered by Mr. S. M. Saxby about eight years ago. He found that when a small magnetic needle was passed slowly in front of a bar of homogeneous iron placed east and west, the needle was not disturbed; but if the iron were not uniform, or contained flaws, its effect on the magnetic needle varied, and the deflection indicated a defect in the iron. Mr. Saxby was thus able to indicate the weak points in a number of bars, and when broken the defects were found to exist. I saw some experiments, and in every instance the needle indicated a flaw; but I am not aware that the plan was tried for the detection of flaws in axles.

Last week I gave the mileage of some crank axles which had broken upon the Midland Railway. The following list shows the highest mileage attained by steel crank axles made by Vickers and Co.:—

| Name or No. of Engine. | Railway Co. | Mileage. |
|---|---|---|
| "Munster" | G. N. of Ireland | 547,965 |
| 17 | South Eastern | 521,246 |
| 251 | L. C. and D. | 479,515 |
| 1,003 | G. S. and W. Ireland | 477,388 |
| 36 | Glasgow and S. W. | 420,517 |
| 152 | M. S. and L. | 415,097 |
| — | North London | 412,536 |
| Old 10. R. 2 | Maryport and Carlisle | 396,753 |
| 204 | L. B. and S. C. | 391,115 |
| 5 | Great Eastern | 376,186 |
| 7 | Waterford and L. | 360,959 |
| 23 | Belfast and N. C. | 348,213 |
| 266 | Midland | 326,102 |
| 14 | G. N. of Ireland | 319,115 |
| 55 | Taff Vale* | 252,938 |

* With the exception of the Taff Vale axle, all the others were at work when the details were compiled.

The above figures are very useful, showing what steel axles can do; but at present there is no similar comparative table giving the performance of iron axles.

Through the courtesy of several companies, I have lately been supplied with a very considerable amount of information which, now tabulated, adds to the data upon this important subject. So far as these inquiries have at present extended, they appear to point to a conclusion that if a "steel" crank axle is destined to break, the failure takes place at an early period in its life, and that if it exist for 150,000 or 200,000 miles there is a great probability that it may run a very great distance. It will be understood that I do not mention this in a spirit of assertiveness, but simply place the suggestion before your readers in order that the circumstance may be considered and further investigated by them. If the conclusion proves to be founded on sound data it will be important, as in such case we shall practically have to wait until some of the cranks which have run an unusual mileage ultimately break, which may be a matter of several years.

The question of crank-axles breaking has sometimes been considered as one of mere "strength," and as steel is stronger than iron, it has been assumed (by "Beginner," p. 284, for instance) that steel must be the best for axles. Now, I contend that very many other matters have to be considered besides tensile strength. An axle may be too stiff and too strong, and this great strength amounting to rigidity, is the principal cause of its own weakness. Extra strain and shock are thrown upon it by its extra strength, and as it will not give way in the least to circumstances, it is absolutely obliged to break. It, therefore, follows that an axle must be strong, but at the same time contain a certain amount of elasticity, and it is not so much a question of simply strength and brute force as of capability to resist strains.

The Board of Trade returns show that during the past four and a quarter years the average mileage of iron axles has been greater than of steel; but, on the other hand, the steel axles had fewer failures. This fact requires attention to be directed to the total axles of each material in use. From a list before me I find that on the 31st December, 1883, there were—

| | |
|---|---|
| Iron crank axles | 6,988 |
| Steel crank axles | 5,955 |
| Straight driving axles | 1,905 |
| Total | 14,848 |

Therefore, when considering the average mileage of iron and steel cranks, it must be always remembered that there are over one thousand more of the former than of the latter in use. I do not advocate any one material or system; but, on the contrary, my object is to fully and impartially investigate this important matter with a view to draw out practical data and conclusions upon a subject that all must admit is not so well understood as it should be.

**Clement E. Stretton, C.E.**

Leicester, June 20th.

## UNITED ASBESTOS CO.'S EXHIBIT AT THE INTERNATIONAL INVENTIONS EXHIBITION.

[24411.]—My attention has just been drawn to the remarks in your issue of 12th inst. *re* this company's exhibit in West Gallery. [See p. 315.]

You state that our machine, albeit ingenious, might have been omitted with advantage, especially as it is shown at several stands—at Treloar and Son's, for instance.

You do not state for what reason you would admit the others and omit ours, and to me it seems that if this rule had been applied to all classes of exhibits, a very small space would have sufficed for this year's exhibition, and we should not have the large numbers of engines, looms, pianofortes, &c., all of which have a much greater resemblance to each other than has our machine to the one cited by your reporter.

If he will, however, take the trouble to examine our machine a little more closely, he will find a considerable difference between the two machines.

Possibly their greatest resemblance is in the noise they make; but in this they are not singular.

Those who are practically acquainted with the history of the asbestos trade, and who have not been dependent on a manufacturer's catalogue for their knowledge of it, will be able to form an opinion of the value of your *résumé*.

Harefield Mills, June 20th. **James Boyd.**

## GAS ENGINES.

[24412.]—"J. K. P." certainly deserves the cordial thanks of the readers of this journal for his valuable letter on page 348. He would certainly greatly oblige me if he would send for publication a sketch of this little motor. Or if that would be encroaching on his kindness, would he communicate with me through the address column? By either of the above he would greatly oblige.

**Invicta.**

## COMPARISONS OF TIDES MADE AT LIVERPOOL AND FLEETWOOD, IN MAY, 1885.

[24413.]—The accompanying comparisons have been made as usual, by collating the observations made at George's Pier, Liverpool, with those at Fleetwood, so as to insure accuracy. It will be seen that the barometric conditions have been not unsteady, and the accordance, therefore, has been sufficiently precise. The Meteorological Office reports that from the 3rd of May to the 9th of May

COMPARISON OF TIDES FOR MAY, 1885, AT LIVERPOOL AND FLEETWOOD.

the distribution of pressure was chiefly *cyclonic*, but complex, and the gradients were slight. In the following week, the distribution of pressure was constantly changing; but not abnormal. Then followed a *cyclonic* continuance of disturbances, some of which were violent; and, lastly, a succession of gales from the S.W., the effect of which, on the sea-level, was very perceptible. **James Pearson, M.A., F.R.A.S.**

Fleetwood, June 8.

## MATHEMATICS AND PHYSICAL SCIENCE.

[24414.]—THE true student of physical science cannot, I contend, advantageously work by rule of thumb; but there are, no doubt, those whose calling necessitates only a superficial acquaintance with registered scientific facts, and who would, therefore, do little better than waste time and endanger their worldly prospects by any serious attempt to dive deeply into the profundities of advanced mathematics. Nevertheless, in simple cases, such as I had in view when addressing my letter to your valuable journal, I feel convinced that the reason for each particular process should be clearly set forth.

The sailor whose knowledge of logarithms, &c., consists in being aware of some of the uses of certain tables, has this knowledge kept alive by the continual working of problems involving constant reference to these tables.

But with the architect and engineer, who should always possess a good all-round acquaintance with natural philosophy, questions connected with first principles sometimes arise which even an everyday familiarity with text-book formulæ would not enable him to decide. For such a one a little solid mathematical knowledge ought to be considered absolutely indispensable.

It would be indeed well if, in accordance with your correspondent Mr. L. Edmunds' suggestion (24385, June 19th), some one would publish a well-digested and logically-arranged mathematical course suitable for the general student. For geometry we have, it is true, a grand and inimitable textbook; but Euclid's elements; to which I refer, are seldom intelligently expounded, the result being that one proposition is but imperfectly understood when the learner is required to pass on to the next. A teacher should, in my opinion, insist upon each figure being drawn with *scale, compass, and protractor*, and strictly in accordance with the method and order of construction observed by Euclid; and, moreover, all the subordinate propositions employed in working out a problem should be repeated during the lesson, which should include the graphic proof, and some information about the application of algebra to geometry. Instruction imparted in this manner is interesting to the young mind—the true object of the work is perceived, and disagreeable toil becomes pleasant exercise.

**Recte Faciendo Securus.**

[24415.]—MR. LEWIS EDMUNDS (24385, p. 349) scarcely meets the complaint of the writer on "Cramming in Physico-Mathematical Science," 24362, p. 327. So far from the one letter answering the other, they have no sort of relation, and both are perfectly true. It is most mischievous work when teachers permit students to merely charge their memories with formulæ, instead of making them thoroughly grasp principles with their understanding. In this way dishonest teachers may no doubt enable lazy and stupid students to gain marks in an examination over those of intelligent, conscientious learners. But the ultimate result is that pointed out p. 327, the production of addled, stupid brains in the possession of ignorant and conceited people put into positions they are utterly unfit for.

On the other hand, in practical and for known specific purposes, mere formulæ may be amply sufficient without any comprehension of their *rationale*. It is quite true that "our ships are navigated over the whole world on this principle." But why? It is known that certain formulæ applied to angular measurements of the positions of the heavenly bodies will give us the position of the observer on the earth's surface. By the aid of books easily carried, a navigator can do his work accurately, although he has no comprehension whatever of the principles of spherical trigonometry or of the astronomical laws on which the formulæ are based. But then he has only to apply mechanically a single formula to a single known case; his personal part of the matter lies in taking the observations accurately, and in working out the figures. The case is not analogous to that of a student who is learning principles which may have manifold applications in the future, and who needs not only formulæ, but the knowledge how to select and apply the proper formula to any one of many possible cases. But the captain who knew no more of navigation than a few cut and dried formulæ for the application of logarithms would be very untrustworthy and helpless in those very probable conditions where his books were not available. There is another navigation always carried out, though usually disregarded, which comes into serious use when observations are impossible and the formulæ useless.

The subject is summed up in the remark I have often made, that mathematics are a most valuable servant, but a most dangerous master. They are invaluable tools of thought: this is Mr. Edmunds's side of the question. They are most dangerous substitutes for thought: this is the aspect of "Recte Faciendo Securus." The two are describing the two distinct sides of that shield so often referred to.

The student ought never to be permitted to use a formula in his scientific work until he has thoroughly mastered the principles and objects of his work itself. **Sigma.**

# REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[56031.]—**Reservoirs (U.Q.)**—Your query is too vague. Are your tanks vertical, like a bucket, or horizontal, like a Cornish boiler? Is there not a mistake in the wording, which speaks of the pressure *outside* the tanks?—GLATTON.

[56039.]—**Explanation Wanted (U.Q.)**—"A Constant Reader" will see, if he looks again, that what he calls ·9in. is printed with but one dash, meaning ·9 *feet*. The last part seems to be rather confused by the fact that the figures are printed in one sentence. They should stand thus:—

$$48\text{lb.} : 125\text{lb.} :: 32 : \frac{v^2}{\cdot 9}$$

Having found this value, the rest follows as another sentence. I see W. Morshead has not gone into small fractions.—GLATTON.

[56061.]—**Vapour Density.**—Mr. W. John Grey says: " . . . what would be the volume of vapour under standard conditions . . . a litre will weigh 4·4493grm. . . . Vapour density is 49·167." How can this be demonstrated? Vapour is simply liquid water transformed by heat into steam, thereby acquiring an increase in volume which textbooks estimate to about 1,700 times. (Let me observe *en passant* that in true science there are no "abouts.") Most certainly this expansion of liquid water is not an "about," but is an absolutely precise one, the proportions of which do not vary. As it takes place in every direction—length, width, and height, it is cubical. Well, 1,700 is not the cube of any number, therefore it cannot be correct. It was adopted, in consequence of Gay Lussac's empirical experiments, by which he found the expansion to be 1,698 times; but he gave no scientific base, no physical law in obedience to which the phenomenon was produced, and therefore, could give no mathematical equations of the constituent elements. However, as scientists don't know better, let us take their "about" as correct, until they acquire the conviction that it is 1,728, the cube of 12. One litre of water is 10 × 10 × 10 = 1,000 cubic centimètres in volume and 10 × 10 × 10

= 1000 grammes in weight; when transformed into steam its weight remains unaltered, but its volume is about 1,700 litres, weighing 1,000grm. If we divide 1,000grm. by 1,700cc., we find that the weight of one litre steam is 0·5882grm., and not 4·4493. Should the last number be right, it would give 7·5638k. as the weight of one litre of water, instead of 1k. or 1,000grm. Ganot, whose "Physics" is very often referred to, says: "The density of vapour at 100° C. and 760 pressure is = 0·6235. The weight of one litre of dry air at 100° is $\frac{1\cdot3\text{grm.}}{1366}$ = 0·951grm. Therefore, one litre of saturated vapour at 100°, press. 760, weighs 0·951grm. × 0·6235 = ·592grm. To find at same temperature and pressure the volume occupied by one gramme of vapour, you have only to divide 1grm. by 0·592, the volume = 1 litre 689 = 1689 cubic centimeters. In transforming into water takes a volume nearly 1,700 times greater than in its liquid state (– 11)." But Ganot's numbers are subject to correction. He takes the weight of air as 1·3grm., whereas it is 1·2932. Therefore, the expansion is not 1,689, or nearly 1,700. It is exactly as follows:—1 × 3 × 4 = 12 × 12 × 12 = 1,728. This, being based upon the respective forms, volumes, weights, and numbers of the atoms of the molecules of the gases and steam, and of liquid water. The density of liquid water is $12^3$ that of its steam, and *vice versâ*. Before Foucault, H was considered as being 0·0691, which × 2 = 0·1382 × 8 = 1·1056 + 0·1382 = 1·2438, which, divided by 2, gave 0·6219 as the density of vapour. Foucault having found that H = 0·06926, which × 2 = – 13,852 × 8 = O = 1·10816 + 13,852 = 1·24668 volume of vapour, which, divided by 2 = 0·6234 as its density, proving the great merit of Gay Lussac's experiments in which he found O – 6238. Again, H = 0·06926, O = 55408 – H O vap. 0·6234, or 0 06926 × 9 = 0·6234. All this disagrees with Mr. W. John Grey's numbers. In No. 948, May 28th, 1884, this gentleman wrote that the respective proportions of H and O in one volume of water were 1,240 vol. of H, and 620 vol. of O = 1860 vol. H O. Can this be correct? As the expression volume has no precision, let us use a well-known and precise measure—the foot. If Mr. W. J. G.'s numbers are correct, one cubic foot of water contains 1,240 cubic feet of H and 620ft. of O = 1860 HO. In a gas holder let us introduce first 620 cubic feet of O, and, second, 1,240 cubic feet of H. The first gas, being sixteen times as heavy as the second, in obedience to the law of gravitation will remain at the bottom, and the second will float at the surface: but no. Not so obedient, the gases. In spite of such universal law, the heaviest will rise up and the lightest will fall down, and they will mix and equilibrate. This I should like to see scientifically explained by a physical law, not be a scientist's opinion. The mixed gases are said to have a great affinity (?) for each other. Still, in spite of it, if not otherwise acted upon, they will remain for ever in that state, and their volume will stand = 1860 cubic feet. They are aphone, silent, invisible, gaseous, and cold. If you ignite them they explode, thereby producing a great noise, heat, light, and visible steam; but the 1,860 cubic feet will be reduced to 1,240. What has become of the 620 cubic feet disappeared? By what were the explosion and noise produced? How and what with cold invisible gases have they produced heat, light, and visibleness? Which are the constituent elements of the two fluids, and their respective proportions? How did the invisible become visible but colourless? Now, the product being 1,240 cubic feet of steam, the latter is at a high temperature. If left to cool, the 1,240 cubic feet, according to textbooks, will be reduced to 1,240 divided by 1,700 = 0·729 cubic feet of liquid water. What was there in steam that caused its volume and has disappeared in cooling? So, 1,240 cubic feet of H and 620 cubic feet of O = 1,860 cubic feet HO don't produce one cubic foot of liquid water, but only 0·729 cubic foot, as stated. Now, let as take one cubic foot of liquid water, and by application of heat let us transform it into steam. According to textbooks we will obtain about 1,700 cubic feet of steam (exactly 1,728) composed of 1,700 cubic feet of H and 850 cubic feet of O = 2,550 cubic feet of gas mixture (exactly 1,728 + 864 = 2,592), and not 1,240 H and 620 O = 1,860 cubic feet HO as indicated by Mr. W. John Grey. Analysis and synthesis agree perfectly.—Ch. Rabache.

[56068.]—**Adjusting Telescope for Collimation in Dumpy Level (U.Q.)**—The following is extracted from Rankine's "Civil Engineering":—Make two bench marks about ten chains apart; set up the level exactly midway between them, and read staves set up on them, so as to find by the difference of those readings the true difference of level of the bench marks. Now set up the level beyond one of the bench marks, and read both staves. If the difference of the readings deviate from the true difference of level, alter the inclination of the telescope by means of the plate-screws, until the readings of the staves give the true difference of level, and bring the bubble to the middle of the spirit level by means of the adjusting screws which connect the level with the telescope. —Glatton.

[56090.]—**Lubricating Bearings (U.Q.)**—Do you want bearings for a wooden shaft? There are so-called self-lubricating bearings advertised in the engineering journals, but they would not do for wood, I think. They are made by drilling a number of small holes, say ⅜in. diameter all over the inner surface of a pair of brasses, and then inserting plugs of antifriction metal in them. There is thus more of this metal than of brass on the wearing surface.—Glatton.

[56141.]—**Lobster-back Cowl (U.Q.)**—Why not lap the pieces alternately, one inside, the next out, and so on?—Glatton.

[56154.]—**Working Strain (U.Q.)**—I presume F. Search means stress, not strain. I cannot find the results of any experiments on the transverse strength of shear steel. Rankine gives 118,468 as the tensile stress to break it. Assuming 118,000lb. as the transverse stress, the weight in the centre of your bar will be given by the formula—

$$w = \cdot0982 \times \frac{4fa^3}{l}$$

$$= \cdot0982 \times \frac{4 \times 118000 \times \cdot5 \times \cdot5 \times \cdot5}{3}$$

which gives 1,935lb. as the weight which would break it. As the data are so uncertain, a large factor of safety should be allowed, which will also depend on the kind of load to be applied, whether "dead" or "live."—Glatton.

[56188.]—**Pump (U.Q.)**—A chain pump will probably suit you. Write to any hydraulic engineer.—Glatton.

[56540.]—**Westinghouse Engine for Flour Mill.—(U.Q.)**—As no one else seems to have noticed this query, I will give you an opinion on some of the points. The first is the question of engine and boiler power. The Cochrane boiler, with 160 square feet of heating surface, would drive a 10 horse-power engine all right provided 10 horse-power would be sufficient to drive your mill and machinery. As to the engine, by all means have a compound. The 10 H.P. compound with 6½in. and 10in. cylinders, 12in. stroke at 180 revolutions a minute, would be far superior to the simple 10in. by 20in. cylinder engine, or the high-speed Westinghouse; so that I should most unhesitatingly recommend the compound engine. The economy in a compound engine, be it large or small, depends on its steam pressure. Thus, a small compound, with a good boiler pressure of, say, 80 to 90 to the square inch, would be economical, whilst a 50 horse-power compound, with 20lb. or 30lb. steam only would fail to be better than an ordinary engine. If I wanted as little as three or four horse-power even, I should be inclined to use a compound with perhaps 100lb. pressure or more, rather than a simple high pressure. Your Cochrane boiler would be very ample for a 10 horse-power compound; but I would not expect it to drive a 10in. by 20in. cylinder. I would with pleasure help you with plan of shafting, &c.; but very much depends on the disposition of the machinery. If the well has a constant supply, you might utilise it for feed. But can it be depended on to give a constant supply? I should also sink a catch pit at a convenient spot in the rivulet, and also connect a pump with that, so that all the available water could be got. As with a condensing engine, you will want a good volume of water. But even that can be managed by the use of a cooling pond, so that the same injection water is used over and over again. In fact, inside the realm of mechanics, very few things are impossible to those who understand their business.—Invicta.

[56571.]—**Electrical.**—"Bobadil" says, "In decomposing water, two volumes of H gas are obtained for every volume of O"; but he does not say the respective proportions of Ag, H, and O. "J. H. E. D." says, "Two volumes of hydrogen are given off for one of oxygen; by weight one of hydrogen to eight of oxygen." Again, nothing is precise. S. Bottone says, ". . . . You decompose 9 grammes of water and produce 11 litres of hydrogen and 89 litres of oxygen." Well, one litre of H weighs 0·0896grm. × 11 = 0 9856grm., one litre of O weighs 1·4330grm. × 89 = 127·5370grm. together 128·5226grm., so that in decomposing the 9 grammes become 128½grm. Is it possible? Eugene Brown says, ". . . . decomposed per second, ·0000945grm. = 1,764 cubic centimètres, setting free ·0000105grm., H = 1,176 cubic cent., and ·000084grm. O = ·0588c Well, one gramme of water is 1cc. It produces 1,728cc. of steam containing 1,728cc. of H and 864cc. of O = 2,592cc. HO. If one cubic centimètre of water contains only 2,592cc. of gases, how can ·0000945grm. produce 1,764cc.? ·0000945grm. cc. of water transformed into steam increase about 1,700 times in volume = ·1607500cc. in steam, and ·2411250cc. in gas, not 1·764cc. It is true that 1,176 + 588 (not 0588 as printed) = 1,764. True, also, that ·0000105 + ·0000840 = 0000945; but there remains to be proved that such propositions can be obtained. At all events, there is a great discrepancy with Mr. W. John Grey's numbers and Mr. S. Bottone's proportions. Now "X. Y. Z." says, "One gramme of water when decomposed yields 1·24 litre of hydrogen, and ·62 litre of oxygen, or 1·86 litre of mixed gas. Mr. Bottone says 11 litres of H and 89 litres of O, 1·24lit. of H × ·0896grm. = ·1111, and ·62l. of O × 1·433grm. = ·88846, together ·99956grm. = one gramme of water. This is right: the rest is not.—Ch Rabache.

[56575.]—**Galvanometer.**—To "Nun. Dor."—Yes, sir, this query is asked very seriously indeed; but I should mention that the instrument is not for serving the orthodox purpose of testing currents, but for a totally different object. What I really want is fully stated in query No. 56081; but I have been informed, through the medium of this journal, that what is asked there is next to impossible. My grief at hearing this may be imagined when I say that I have spent three years of labour on the machine in question, and this is the last link in a long chain of difficulties. If "Nun. Dor." could render me any help in the matter, I should be thankful. —J. Budge.

[56583.]—**Chloride of Zinc.**—If "Old Reader" must have pure zinc chloride, there is no help for it but to pay the price. It is sufficiently pure for battery purposes when prepared from bar zinc or spelter and hydrochloric acid.—S. M.

[56584.]—**Silvering Solution.**—This querist should look up the recipes in back volumes, and select those which seem most likely for trial. I presume the solution he refers to was a real silver preparation, and not merely nitrate of mercury.—E. G. M.

[56587.]—**Telephone System.**—The current passes direct to B, when the intermediate offices are not put into circuit, which of course they are not unless the telephone is removed from its hook.—S. M.

[56587.]—**Telephone System.**—In your issue of the 29th ult., will "R. F. S." tell me how many cells and kind of battery is required to work this system? I have tried 20 cells Leclanché, No. 2 size; but only works between first and second office, and no further.—T. J.

[56595.]—**Spectroscope.**—I, too, should like to know how to make a spectroscope for 5s., or even a little more. Will any of your readers help?—Essar.

[56599.]—**Photographic Plates.**—Has this querist consulted the makers? Does he adopt the formula and practice recommended by them?—T. J. P.

[56609.]—**Analysis of Asbestos.**—The following analysis shows the composition of Italian and Canadian asbestos:—

| | Italian. | Canadian. |
|---|---|---|
| Magnesia | 40·18 | 33·21 |
| Protoxide of iron | ·75 | 5·77 |
| Alumina | 2·82 | 6·69 |
| Silica | 40·25 | 40·92 |
| Water of hydration | 14·20 | 12·20 |
| Soda | 1·37 | ·68 |
| Potash | traces | traces |
| Protoxide of manganese | traces | traces |
| Lime | traces | traces |
| Chlorine | ·15 | ·22 |
| Sulphuric acid | ·31 | traces |
| | 100 03 | 99·69 |

—S. M.

[56620.]—**Steam-Carriages.**—To "Invicta." —Will you obligingly allow a French subscriber to avail himself of your kind offer? I intend to procure a vehicle to which I will apply the new boiling-oil system. I wish to know—1st, what room, length, width, and height will occupy an engine of 1-h.p., without boiler, with variable cut-off (détente) fit for the purpose; 2nd, at how many atmospheres pressure it would work; 3rd, the number of piston strokes per minute; 4th, the quantity of steam used at each stroke; 5th, and, if possible, about the cost price? Would the Parkyns engine do? In April last I asked the above question to the Paris establishment, Cail and Co. I received the answer that, as they do not construct engines of so small a power, they could not give the required information. I thoroughly believe that any English engineer can supply such information, and I expect from your kindness that you will please to send it to me either through the "E.M." or direct.—Ch. Rabache, Morchain, Somme, France.

[56620.]—**Steam-Carriages.**—The question of steam-carriages on common roads very often appears, in answer to queries, in your columns of late, and as most of the answers relate to now nearly forgotten attempts, I send you for use the following account of a modern steam-carriage which does its work very satisfactorily. Two friends of mine in Alsace are in the habit of using a powerful steam-carriage for running on common roads; it weighs, when in working order, about $2\frac{1}{4}$ tons and seats four persons; the proprietors have a concession from the Government to run at a rate of $12\frac{1}{2}$ miles an hour, but under favourable circumstances this speed is considerably exceeded, 25 miles an hour being occasionally obtained. The sensation at this speed is very exhilarating—infinitely more pleasant than in a carriage drawn by horses the jerking movement being absent, it has more likeness to sailing. This machine gave considerable trouble at first; but now, thanks to the patience and intelligence of the owners, the carriage is in very satisfactory running order, and seems to demonstrate what can be done with this class of vehicle by a judicious expenditure of money and in a country where the authorities do not needlessly meddle. I hope my friends will get a new carriage built, embodying improvements which practice with the present carriage has suggested. The great difficulty now experienced is with the tires: they are of iron, about 4in. by $\frac{3}{8}$ or $\frac{3}{4}$, and three sets had been completely demolished by the time the carriage had run some 3,200 miles, so that a new set of tires are called for about every 1,000 miles. Now the wheels are of wood and extremely rigid, and I believe the excessive rigidity of the wheels is the cause of this excessive amount of wear, and would point out as a remedy an elastic wheel. The makers of slow-moving traction engines have already found this out, and are endeavouring to produce a good elastic wheel. The steering gear of this carriage is simply perfect. The steersman (who is, at the same time, engineer) has the machine perfectly under control, and can execute manœuvres which would be impossible with a horse-drawn vehicle; the ease with which it is guided, even at the highest speed, gives great confidence. The carriage was built by Mr. Ballée, of Le Mans, France.—C. B., Zurich.

[56620.]—**Steam - Carriages.**—"Nun. Dor.," answering on p. 352, imagines that "Progress," in his letter, p. 328, means a steam tramway, when, in fact, "Progress" does not believe either in steam engines on highway roads, nor in any way trammelling the wheels of vehicles for speeds under ten miles per hour. We will, therefore, drop steam-carriages of the past, and refer to motive power and vehicles for use on highways in the future. A "tug of war" was mentioned on p. 328 as now proceeding between flat tire and flange wheels, or tramcar versus omnibus on the same rails, both being drawn by animal (horse) power, and the opinions of readers of the "E. M." was required as to the relative advantages of the two systems, each having an iron or other such bearing surface as "Nun. Dor.'s" description of the word "rail" on p. 352. An iron rail 8in. wide on the surface can be made and fixed at as little cost as a groove rail, the groove having to be ploughed out after the rail is rolled into shape and the quantity of iron in each would be about the same. My idea of an improved highway road is one that shall present the least possible resistance to the rolling of wheels, thereby requiring the least possible motive power, causing the least wear, and allowing the lightest vehicle to be used. Also, that the road should at all seasons of the year be dry on the surface and free from dust and slush. To arrive at such state, we must give up the system of carting gravel on to the road to be ground, the same as we cart wheat to the mill to be made into dust (flour), then with good surface draining and using mechanical motive power, we shall be rid of the horse-droppings, dust and slush, and have a clean, dry road at all times. "Up and down" tracks or ways should be provided, say, each 6ft. wide, which would accommodate all descriptions of vehicles, including a groove for flange wheels if required, and the traffic regulated as on railways. Now, as to motive power. Steam-engines are of great weight; and, of course, every foot of the road they travel, must be sufficient to carry that weight when the vehicles with their loads only require one-fourth part of that strength, therefore, 4lb. must be expended on first outlay on road for engine when only 1lb. is required for the loaded vehicle. As to steam-engines in the future, Sir F. Bramwell, in an address this year, "prophesied a great future for the gas-engine and the relegation to museums of the steam-engine as an old curiosity." Either gas, oil, or spirit could be sold to travellers at all country inns abutting on the highway roads. The first cost of road would follow almost directly in proportion to the quantity of iron used, and that must be governed by the weight the road has to carry; therefore the great necessity of reducing the weight on any one wheel by adding more wheels to the load. Having for some few years given attention to the question of highway roads, I believe they can be greatly improved, and, in proportion to advantages gained, the expense would not be more than it has been. The "poor man" would be able to travel with his own iron horse (pedal machine) and carry as great a load as farmers have hitherto done with their one-horse market carts. Out of about nine or ten queries and statements in my letter on p. 328 only one has been replied to (that giving definition of word "rail.") If readers of "E. M." will kindly discuss the others we will then proceed with description of vehicles and motive power required for the future.—Progress No. 2.

[56650.] — **Lead - burning.**— It would be interesting to learn from Mr. P. J. Davies and Mr. H. Holmes what they mean by the gas being "dirty," and how they recognise it. The simplest method of procuring hydrogen is to pour a dilute solution of sulphuric acid on granulated zinc, when the zinc becomes sulphate of zinc, and the hydrogen of the acid is evolved. An ounce of zinc should liberate about $2\frac{1}{2}$ gallons of gas; but scraps of iron may be used instead—only in that case the gas will be less pure, being contaminated by the presence of compounds of hydrogen and carbon. Is it this carbon which is objectionable to the plumber? Gas made with zinc and common brown vitriol is often contaminated with compounds of hydrogen with sulphur and arsenicum; but surely these are not of much moment in autogenous soldering. If it were not for the risk of getting some carbonic oxide, one would think the best plan for plumbers would be to pass steam through a tube filled with red-hot iron borings and turnings. I suppose that is why they use acid and zinc.—Essar.

[56650.]—**Lead-burning.**—If Mr. Holmes will look to my reply on page 287, he will find that I never spoke of druggists selling bad sulphuric acid; but simply oilshops, for though I have on many occasions, when short of acid, endeavoured to procure such good enough for the work, I have never on any one occasion been able to obtain a suitable material from these shops: hence the reason for my speaking—to put my readers on their guard; and considering that I have been something like thirty years in the trade as a professional lead burner, I think I am justified in cautioning my readers against an evil which is universally, by experienced lead burners, admitted. And with regard to using a pack of old rubbish, such as ventilators and watering cans, it is simply utter nonsense, for such trash would be far more trouble than the preparing and burning put together, and I trust that my readers, if ever they have attempted to use such worthless rubbish, will at once ignore it, and use the proper material, or melt the old zinc down into bar zinc. Mr. Holmes asks me the question as follows: "How does Mr. D. make out that the gas is dirtier the first half-hour than after?" and says, "This is contrary." I say it is not so, and I herewith give substantial reason for my assertion. For argument sake, suppose yourself to be at work in a soap works, oil refinery, vitriol works, and the like dirty places. When you first charge the machine with pure bar zinc the outsides of the zinc are liable to get fouled with vegetable matter, or, for argument sake, greasy and dirty; even the breaking up of the zinc with the hammer, or it knocking against rusty iron is sufficient to foul it. Now, it is a sure thing if any vegetable or oily matter be present when the zinc is first put in the machine, it will at once colour your acid. For instance, drop a little putty, or a drop of linseed oil, or a bit of cork, or such like, into some best sulphuric acid, and you will at once see a discolouration, which will take place exactly the same in the machine; but after a little time the surface of the zinc becomes clean, and the dirt exhausted; but during this time your gas is impure, and according to the amount of foreign matter so will the dirtiness of your gas last. Mr. Holmes says that I keep harping about my book. I am not quite sure as to the *harping*; but simply gave it to show that his words of last week were published, and that he was using my own instructions; and as to the readers of the "E. M." not being able to purchase all the books that are written and published upon the subject, they could very easily do so, considering that there is only one admitted of any practical worth, and which has been published in the columns of our "World of Science," and which is accessible to all readers of the "E. M." who may wish to purchase the numbers at the present moment, if they would only look through the Sixpenny "Sale" Column, &c. I should like Mr. Holmes to properly reply to my question on page 329, wherein I asked him if there is nothing to be done but to throw the acid away, which I see he has forgotten; by doing so he would be giving instructions to many of the uninitiated, and it looks bad for me to answer my own question when in correspondence with a contributor like Mr. Holmes, who says he is willing to give instruction to the young beginner. Trusting he will do so, for although this appears an insignificant question, nevertheless it is one which is not generally known, and which undoubtedly will be useful to others besides the young beginner, whom Mr. Holmes says he is willing to give instructions to.—P. J. Davies, 78, Earl's Court-road, Kensington, W.

[56651.]—**Explosion of Gas in Boiler Tube.**—The cause of the above has been fully explained. I rather expect the explosion took place on closing the fire-door, not opening it; at least such has been my experience, and after more than forty years' hard firing, I never witnessed it with any other boiler except the tubular class, the last boiler I worked, after being driven backwards many times on to the coal-heap, with whiskers and eyelashes cleaned off. I had to close my fire-door very gradually after every charge. Let "A. T." do this, especially first thing in the morning, and the like will not occur. Narrow flues and small damper-hole have much to do with it. If the gases have plenty of room to expand, and get well away up shaft, they would not come out at fire-door.—Hinckley Man.

[56672.]—**Varnish for Wall Papers.**—Dissolve 8oz. of alum and $3\frac{3}{4}$oz. of Castile soap in four pints of water and 2oz. of gum arabic and 4oz. of blue, separately, in four pints of water; mix the solutions, heat slightly, and dip in the single sheets, which hang up until dry.—A. B. C.

[56722.]—**Flywheel.**—Many thanks to S. Beeching and "Invicta." I want the engine to work a lathe or small planer. I should like if possible to alter my query. Would the flywheel do 18in. dia., as it would suit the bed better? And as "Invicta" thinks speed too high, will reduce it to 300, cut-off being at $\frac{1}{3}$ stroke. The rest of my query to remain the same.—M.

[56733.]—**Problem.**—On p. 353, "J. C." says that my answer to this question is incorrect because I supposed a mistake in the question; but "J. C." assumes in his solution that in the eleventh line of the question "100 gallons" should read "10 gallons"; whilst in the other answer on p. 310 it is assumed that the correct reading is "100 gallons more than B. did." There is evidently some mistake in the question, for, taking it as it stands, we have $800n + 100 = 225n$, whence $n = -\frac{4}{23}$ which is clearly wrong. Can "Trophy" say where the mistake is?—East Anglian.

[56750.]—**Gold Plating.**—Add to a saturated solution of nitro-muriate of gold about a fourth part of sulphuric ether; shake the mixture, and then allow it to settle. The ether will take the gold from the acid, and will separate itself from it also, and form an upper stratum in the vessel. Carefully pour this etherial gold into another glass, and immerse in it any utensil that is highly polished; then take it out, and instantly plunge it into water, when the surface will have acquired a coat of pure gold, which will stand polishing. You may use a pen and draw figures on razors, &c., and the gold will remain on them as just described.—W. E. S.

[56753.]—**Horse-power to Drive a Millstone.**—As T. M. Bury has not yet received any reply, I give him a rough-and-ready one amongst us millers; that is, one horse-power per foot diameter of stone, but with a little extra power you will drive stronger and better everyway, especially as your stuff is very hard, and (of course your stones are French) you will have a little power in store for any additional machinery. I should say put six horse-power behind them.—Hinckley Man.

[56759.]—**Waterproofing Canvas.**—Ingredients: 96 parts of ochre, 16 parts of lampback, boiled oil, two parts of yellow soap, eight parts of water. Mode: Mix to a thick paint the ochre, and lampback, with the boiled oil; then mix the yellow soap and water, and add them to the others, stirring all well. Dress the canvas with two coats of this mixture, leaving time to dry; then give one dressing of lampblack, and boiled oil only, mixed to the consistence of a thick varnish.—W. E. S.

[56770.]—**Putty.**—Ingredients: 10lb. of whiting, 1lb. of white lead, boiled linseed oil, a wineglassful of sweet oil. Mode: Work up these ingredients with sufficient boiled linseed oil to form a paste of the requisite consistence; the sweet oil prevents the white lead from hardening. All putty should be made some time before it is used, and sashes to be puttied should have one coat of paint, which will cause the putty to adhere more firmly. Old putty may be softened by applying rags dipped in a solution of caustic potash for some hours, or by rubbing a hot iron along the putty.—W. E. S.

[56777.]—**Paste Blacking.**—Ivory black, 1lb.; treacle, $\frac{1}{2}$lb.; olive oil and oil of vitriol, of each 2oz.; water, a sufficient quantity.—W. E. S.

[56780.]—**Camp Stoves.**—Perhaps a stove just made for me by the Albion Lamp Company would suit inquirer. It is made of galvanised iron, duplex $4\frac{1}{2}$in. wicks, and is a cube of about 14in. I use it on a small yacht; but as it has wind shutters, I think, if it is not too large, it is worth notice. After repeated trials for small yacht stoves, I am at last satisfied. It burns crystal oil. If only a kettle to boil is required, a 3d. spirit reservoir will answer well, put inside a shallow tin box: that is my kit for river excursions of one day.—R. Hannen.

[56794.]—**Storage Batteries.**—I should not advise the querist to use storage batteries at all for such a number of lamps, unless it is absolutely necessary; they are a great deal of trouble. The lead that comes on teachests is no use whatever; it is much too thin. If an "Old Subscriber" would state the E.M.F. of his lamps, and the current they take, then, perhaps, I could help him. If they took 60 volts and one ampère, he would want 30 cells, in series, each cell containing about 30 plates. Then the size of the plates would partly depend on the time the cells were required to light the lamps. The total force required to light the lamps is about $\frac{60 \times 30}{746}$, or nearly 2½ horse-power. Perhaps some one will be able to give some better advice than myself; but, if not, and the querist will tell me the E.M.F. of his lamps and the current they take, I will try my best.—Bunsen.

[56800.]—**Pianoforte - Tuning Hammer.**—There has been no recent improvement in this article, and the choice still lies between the "T" and the "lever" hammers, as it did 50 years ago. For a beginner, the lever hammer is perhaps more convenient, as he will obtain better command of the pins. Either may be obtained of Hughes, Drury-lane, or at Buck's, Tottenham Court-road. W. H. Davies.

[56813.]—**Fracture of Water-Gauge Tube.**—"Bacchus" must have been very fortunate, or had but a short experience. He omits to notice that iron wire is specified, and it is an indisputable fact that water-gauge tubes, barometer tubes, and the like will often go after they have been cleaned. It is probable that they have been slightly scratched by the iron wire. Besides, that is a method employed for purposely breaking tubes of the kind. I believe the barometer-makers use a piece of whalebone, or else a brass rod carefully covered so that no part of the metal can touch the glass. If the glass tubes were thoroughly annealed, they would probably withstand even scratches from an iron wire.—Nun. Dor.

[56814.]—**Hot Food in Hot Climates.**—The physiological effects of spicy, hot foods is to keep up the internal temperature at times when the heated air becomes oppressive, so that the outer temperature would inevitably rise so nearly to that of the vital organs as to produce faintishness and sunstroke. In days gone by the diseased and disordered state of the liver, &c., which rich old "Nabobs" brought home from India and other tropical regions after some years of residence there, were usually attributed to the curried and other spiced dishes of food; but recent experience shows that the real cause of such loss of health arose from the mistaken practice of trying to live in English fashion—on heavy meats and malt and other intoxicating liquors—instead of adopting the foods of the country—viz., the various grains and fruits used by the natives. Those who find this summer weather oppressive may cool and refresh themselves by lunching on a bowl of wholesome soup nicely cayenned. Just try it, and you will thank H. O'B.

[56819.]—**Pickle for Brass.**—After the brass surface is got by some other means (either by polishing, burnishing, or scratch-brushing) as clean as possible, put the goods into aquafortis and water, and leave them there for some hours according to circumstances. The acid will eat away the outer coat, leaving a bright surface beneath. The brass is now put into hot sawdust, and shaken about to dry and clean them, when they will be ready for lacquering.—A. B. C.

[56822.]—**Small Dynamo.**—To Mr. S. Bottone.—You might use No. 16 on the armature and No. 14 on the field. Fill the spaces on the ring with No. 16, having previously weighed the ring. Weigh the filled ring. One quarter the weight will give the weight of an equivalent resistance in copper wire. (See any table of wire resistances; one was published last year in the English Mechanic by Mr. Sprague.) Now coil the F.M.'s with No. 14, rather more than is required to balance the resistance of the armature as just found. The quantities will be found to be 1½lb. of No. 16 and 4lb. of No. 14, nearly. If you can test the resistance by means of galvanometer and Wheatstone's bridge, you will get much more accurate results.—S. Bottone.

[56823.]—**Steam.**—The number of cubic inches of steam admitted into the cylinder is $32^2 \times 7854 \times 72 \times \frac{2}{10} = 11581{\cdot}05$ cubic inches. The temperature of steam at 35lb. above the atmospheric pressure is 283° Fahr. 1 cubic inch of water will form 554 cubic inches of steam at the above-named pressure. Let the latent heat of steam be taken at 966°. The total heat contained in the steam will be 966° + 283° = 1249°. Let the temperature of the injection water = 50°, and the temperature of the mixture of the steam and water is to be 100°. We then have $\frac{1249^\circ - 100^\circ}{100^\circ - 50^\circ}$ = he quantity of water required to condense a cubic inch of water when formed into steam = 23 cubic inches nearly. Again, $\frac{11581{\cdot}05}{554} = 20{\cdot}724$ = the number of cubic inches of water which were admitted into the cylinder as steam, and $20{\cdot}724 \times 23 = 476{\cdot}652$ cubic inches of water will be required to condense the steam admitted into the cylinder during one stroke. "Young Engineer" does not give the number of strokes the engine makes in a minute. Therefore, I can't tell him whether the air-pump and injection-pipe are large enough, or otherwise.—A. Gray.

[56824.]—**Watch Work.**—Procure ruby pin of proper size, and lay it in so that it projects to proper length from face of roller; then get small piece of shellac and place it on. Now, if you put a piece of wire through the centre hole of table roller, and let the flame from gas play on the wire, the heat will be transmitted, and shellac will flow. Annie.

[56824.] — **Watch Work.** — Slightly different methods are employed to fix ruby pin in roller of lever watch; but the cement invariably used is shellac. The way I proceed is thus: Having found a pin to fit, and seen it is suited to the lever fork, remove the roller. (A special tool is made for this; but if "T. W." hasn't one, he can do with nippers if careful). Then put pin in position: put small piece of shellac on at back, and heat by means of a piece of steel wire, held midway over the gas, and touch with end. If found not quite upright, can easily be adjusted by gently pressing at side with heated wire. Care, of course, to see that no shellac on side or in crescent for guard pin.—Escapement.

[56824.]—**Watch Work.**—Take the roller off the staff, and put it on a tapering piece of steel wire; then warm the wire about 1in. below the roller, taking care not to heat it enough to colour the roller, but only to melt the shellac with which the pin is fastened in. Push out the piece of broken pin if it is still in the hole, and while the shellac is still hot put the new pin in the hole, and put a very little shellac on it (on the under side); move the pin up and down two or three times so as to work the shellac well into the hole, then push the pin in as high as you want it, and let it cool. Scrape off any shellac which may have got on the polished side of the roller with a knife. I may say that I shall be pleased to answer any questions respecting watch jobbing or finishing.—C. A. W.

[56825.]—**Mechanical Question.**—The answer given by "Dubliniensis" to this question is hardly such as will leave the inquirer any wiser. He states the answer without giving any reason for it. "Student" probably knows that the formula for expressing the strength of rectangular beams is $\frac{b d^2}{l}$ when $b$ = breadth in inches, $d$ depth in inches, and $l$ length in feet. The strength being directly as $b$, if we double the breadth, we double the resisting fibres as the square of $d$, as by doubling $d$ we not only double the resisting fibres, but double the leverage also; therefore, we have four times the resisting power. Inversely as $l$, as if double the length, half the strength. In this case, the beam being 10ft. long and supported at an inclination of 60°, the weight acting directly downwards, will fall at a point midway between the supports, which "Student" will find are 5ft. apart. The question therefore resolves itself into a beam 5ft. long supporting one ton at its centre, and by above formula

$$1 \text{ ton} = \frac{b d^2 \times \text{constant of strength}}{l}$$

$$\therefore 2240 = \frac{2 \times d^2 \times 450}{5}$$

$$= d^2 = \frac{112}{9} \therefore d = \sqrt{\frac{112}{9}} = 3{\cdot}53\text{in.}$$

—Fred. A. Robinson.

[56826.]—**Loss of Power.**—If "Student" should feel exercised by the difference between the 1,792 foot-pounds in David Stephen's reply to his query, and the 573·4 f.p. in my reply thereto, the explanation is this:—"D. S." took the coefficient of friction as ·1, which is a fair value for the c. of f. of repose in this case; but he should have taken the c. of f. of motion, which is about ·032, or only about one-third of the other. Probably there would not be time enough for the repose-coef. to get established at the end of each stroke; and even if there were, that coeff. would be completely abrogated before the mass had moved ·1in. after each fresh start; and, therefore, the additional work to be done in consequence of it would be quite inappreciable. All the calculations in "D. S.'s" reply are perfectly right.—Dubliniensis.

[56828.]—**Hot-Water Pipes.**—If you dip your pipes to go under the doorway, they will not work; but if you carry them over the doorway they will. If you are short of room above the door, as is often the case in greenhouses, use four stop ends, and screw into them wrought-iron barrel, half the size of your hot-water pipes to go over the door. You will find this about the only practical way to do your job.—Scott Mason.

[56830.] — **Pianoforte Making.** — To Mr. Davies.—In inquiring as to the back of a soundboard, "A Pianoforte" is probably thinking of double soundboards, which have occasionally been made something after the fashion of a violin. This principle has not, however, proved to be of service in a piano; and I think it questionable whether it is not wrongly applied, though not so palpably, in a violin. I have been in hopes that our esteemed correspondent, "Orderic Vital," would have had something to say on this subject, and trust that it is not yet too late. It is a very common mistake to suppose that the soundboard of a piano requires support against the downward pressure of the strings. Of course it is absolutely necessary to transfer the vibration of the strings to the soundboard, and for this purpose a close contact is required; but this may be obtained quite as effectually by the side bearing of the bridge pins as by the downward pressure of the strings. The traverse bars are therefore only necessary to maintain the rigidity of the soundboard, and are not needed to support it in any other way. It would hardly be worth while to repeat the directions and measurements given in Vol. XXXII., as many of them have since been improved upon; but I hope soon to contribute a series of articles on "The Mechanics and Reinforcement of Sound." Meantime, I shall be glad to send the printed directions referred to, though I cannot undertake to answer queries by post.—W. H. Davies, Irvine-street, Liverpool.

[56831.]—**Removing Zinc from Tin Solder.**—I have a method of removing zinc from lead; but cannot exactly say whether it will do the same for tin. Melt the mixed metals in a ladle, and pour them into any convenient mould (sand will do); the lead will sink to the bottom, and the zinc will come to the top. Before the zinc gets hard, put a piece of bent wire into it with which to raise it out of the mould as soon as it is sufficiently hard. Lift it by the wire, and you will find the molten lead at the bottom. Any lead adhering to the zinc can be brushed of at once, while it is hot. Keep the mixture steady on the ladle, and don't shake it up. It is probable the tin will remain with the lead; but that I can't say, as I have not tried it. Don't let the sand mould be wet, or you will get a lesson which you won't forget.—Os.

[56832.]—**Engine Query.**—Will you communicate with me, stating requirements, and I will do what I can for you.—C. Lilcock, High-street, Stony Stratford.

[56833.]—**Horizontal Engine.**—I do not remember a sketch of a similar engine complete in recent back numbers. But if you will tell me one or two particulars, I will try and help you to what you want. Tell me if the cylinder has feet to bolt to a bedplate or not? Have you not the connecting rod? or slide rod and eccentric? Tell me all the parts you now have, and the sizes, or rather lengths, between centres, and I will, if necessary, send line sketch of engine complete, so that you can finish it to a settled plan.—Invicta.

[56834.]—**Sun-Dials.**—There is a long and fully-illustrated article in Vol. VII. of the *Encyclopædia Britannica* (eighth edition), where the various writers on the subject are also detailed.—Arthur Mee.

[56836.]—**Telescope.**—Tell me the focal length of your 5in. o.g., and I will, with pleasure, give you all necessary instruction how to mount it for use? Also the necessary lenses for a Huyghenian eyepiece, and how to mount them for use. But without the focal length of the o.g. I cannot help you to instruction as to the tube and mountings.—Invicta.

[56836.]—**Telescope.**—The length of tube depends on the principal focus of the o.g., and should be a few inches less than such focus. Of eyepieces the Huyghenian is the one most used, and the proportions of the component lenses are given on an average once a month in these columns. As to powers, I notice that Wray supplies his 5in. telescopes with five—from 60 to 400.—Arthur Mee.

[56838.]—**Telescope.**—"Eyepiece" and others wanting to alter their telescopes would be much safer in intrusting the work to an optician than attempting it themselves, unless perfectly familiar with the whole affair. He may, however, obtain increased power with the least possible amount of tampering by removing from his present eyepiece the lens furthest from the eye, though the "field" will be rendered less perfect.—Arthur Mee.

[56838.]—**Telescope.**—Instead of cutting or altering the draw tube as this querist suggests, I can tell him of a better plan, I think; in fact give him a choice of at least two ways of doing what he wants. Supposing a moderate increase of power only is wanted, then increase the distance between the erector, which is the two lenses nearest the o.g., and the pair forming the eyepiece proper. This, by means of a short piece of tube to screw on, will increase the power. If this is not enough, then why not have a Barlow lens fitted? With this latter placed in a definite position, which he can be informed if he decides to adopt the plan of using a Barlow, the power of the existing eyepiece would be doubled. The Barlow, which is, or should be, a concave achromatic, is easily adapted to the existing tubes. If either of these suit him, I will with pleasure give further details if he proposes to do the work himself.—Invicta.

[56839.]—**Automatic Steering Gear.**—If I wanted to do such a thing to save time, I should try and get an old bottle-jack movement. This gives exactly what you want—viz., the motion reversed every so-long. With the aid of a fly you could also modify the time in which the clockwork would put the rudder over, whilst a wheel and pinion in addition would give additional power, and prevent its working too fast.—INVICTA.

[56840.] — **Rubber Stamps.**— Signatures are made in the same manner as in stereotype plates (of which rubber stamps are only a variation), viz., by getting a woodcut of the signature and proceeding as if it were in type. If "Autograph" does not know how to do woodcuts, he can refer to back numbers, or inquire again.—B.Sc., Plymouth.

[56844.]—**Mathematical.**—If $c$ is the length of the radius of the circle, the polar co-ordinates of the extremities of the chord are $(c, a - B)$ and $(c, a + B)$, and the equation of the straight line through these points is $c^2 \sin. 2B + rc \sin. (\theta - a - B) + rc \sin. (a - B - \theta) = 0$, and this easily reduces to $r = c \cos. B \sec. (\theta - a)$. If we put $B = 0$, we get $r = c \sec. (\theta - a)$, which is the polar equation of the tangent to the circle at the point $(c, a)$.—EAST ANGLIAN.

[56849.]— **Sewing-Machine Motor.** — Your batteries get polarised; they require a little modification. Instead of putting both plates in one cell with the acid, use a porous cell with dilute sulphuric acid in which to place the zinc, and in the outer cell place the carbons in the bichromate solution. You will find this last longer than the ordinary bichromate cell.— Os.

[56849.]—**Sewing-Machine Motor.**—The fault is in the battery, not the motor. The reason is that the plates polarise, and thus reduce the current to a mere nothing, so that the motor perforce slows and ultimately stops. Remedy: Use a constant form of battery. A Bunsen or Grove cell would work it all right.—INVICTA.

[56850.]—**Dynamo.**—To MR. BOTTONE.—Wire on armature rather fine for machine of such size. Of course it will work, if the F.M.'s be wound to approximately balance the resistance of armature when running, which will be about 1·25 ohm. Wind the fields with sufficient No. 14 to rather more than balance this—say, about 18lb. You may expect to find the machine heat considerably if run for any length of time at full speed. Wound as it is, it will light either arc or incandescent, the former perhaps the better of the two. — S. BOTTONE.

[56852.] — **Quart Size Bunsen Cells.**—To "SIGMA"—These questions, relating to special applications in which I have had little personal experience, would be better answered by those who are used to the particular application of the general principles. But the elements of the questions are not so given as to enable me to apply the general laws with which I am familiar. "Arc lamp" is a rather vague definition, as much would depend on the lamp available and the light required. Especially must the size of carbon be controlled by those considerations, and, as I have never had anything to do with the working of them, I should not like to give specific instructions on such details as the best size of carbon. In like manner the resistance of the 20 candle-power incandescent lamp is an essential element of the calculation, as each maker requires a particular E.M.F. and current. In fact, such a set of questions involves a considerable range of the subject of practical electric lighting.—SIGMA.

[56854.]—**Valves in Compound Engines.**—The valves of a compound engine are just the same as those of a simple engine. The cranks are set at right angles. The high-pressure cylinder on the leading cranks, and the exhaust of the h.p. connected to the steam side of the l.p. valve.—REGULATOR.

[56854.]—**Valves in Compound Condensing Engines.**—The valves in a compound engine are very much the same as are used in other engines—there is usually nothing special about them. The high-pressure cylinder is usually fitted with a cut-off valve on the back of the main slide, whilst the low-pressure valve is most usually an ordinary double-ported valve, just as would be used in any other large engine. In marine engines, when vertical, the weight of the slides and links are usually balanced in part by a balance-piston, the steam being, of course, admitted to the underside. These are also of proportionate area to the pressure in the respective valve-chests. The valves of the compound engine are now very much as in the earlier days of steam when used with large engines. If what I have stated does not make it clear to you, I will (supposing no other competent person does so), send a tracing of the valves of the engines of some well-known modern vessel as an example.—INVICTA.

[56855.]—**Inorganic Chemistry.** — Miller's "Elements of Chemistry," Part II. (Inorganic), Thorpe's "Inorganic Chemistry," Odling's "Outlines of Chemistry" (this is a capital book), Wurtz's "Atomic Theory, for Practical Analysis," Fresenius's "Qualitative and Quantitative Analysis." These are all good books, especially Odling's and Miller's.—R. A. R. BENNETT.

[56855.] — **Honours Examination in Chemistry.**—The querist should study the large work by Roscoe and Schorlemmer; also "Cooke's First Principles of Chemical Philosophy," giving special attention to the sums and questions in the latter. He should also read current chemical literature, so as to have some knowledge concerning recent researches.—WM. JOHN GREY, F.C.S. (1st class honours), Newcastle-upon-Tyne.

[56857.]—**Diminished Power of Engine.**—The reason is one of the simplest. It is because when the reversing lever is put in mid-gear or the central position, as our friend terms it, the slide-block being brought to the centre of the slot-link, and which necessarily is the centre of oscillation, receives no reciprocating motion, and hence, as the slide does not uncover the ports, no power is exerted on the piston. Owing to the movement due to the radius of the coupling links from the weigh bar some slight motion is given, generally sufficient to give a trifling admission of steam. Putting the reversing lever in mid-gear is in one sense somewhat similar to nearly closing the starting valve. But in the one case the steam is wiredrawn at the regulator, whilst the action of the slot-links wiredraw the steam at the slide-valves. If I have not made myself clear, shall be happy to further explain. —INVICTA.

[56858.] — **Horse-Power of Engine.** — The querist asks to be told the horse-power of an engine, but as he is entirely silent as to the bore of cylinder, length of stroke, revolutions per minute, ratio of expansion, &c., it would be only possible to give a theoretical reply; therefore, I cannot see my way to tell him the horse-power of an engine that he gives no data concerning. In fact, the query is not in a practical form such as his namesake would have put it. The theoretical horse-power of 100 cubic feet of steam per minute at 50lb. pressure is only one element in the calculation.—INVICTA.

[56858.] — **Horse-Power of Engine.**—Suppose the cylinder holds 100 cubic feet steam, then its length, multiplied by the area of the piston, = 100 cubic feet. Now the area of the piston multiplied by 144 (to bring to square inches), multiply by the length, by 50lb. = 500 × 144 × 50 = the number of foot-lbs. Now—

500 × 144 × 50 = 720,000 = 720,000ft.-lbs. per min.
But— 1h.p. = 33,000ft.-lbs. per min.

$$\therefore \frac{720{\cdot}000}{33\,000} = 21{\cdot}\dot{8}\dot{1}\text{ h.p.}$$

If the cylinder does not hold the 100 cubic feet of steam, but a less number of cubic feet, then 1 stroke will take less time than before. So the answer would have to be multiplied by 1 minute, and divided by the time of 1 stroke, which would come to the above answer.—H. F. L. K.

[56859.]—**Vertical Galvanometer.** — Some people seem to think that whatever appears in print must *ipse facto* be right. Now this is very far from correct; an instrument which is made to be used in a vertical position ought to be so used. It is evident from the query, that when the instrument is placed on its back, the needle falls out of place, probably touching the dial, or the inner needle touching the coil or some other point; the reason "its movements when horizontal are so uncertain," is because the whole thing is out of place (like a clock upside-down), and the best way to remedy same is to restore the instrument to its correct position and use it in the manner for which it was specially constructed. —Os.

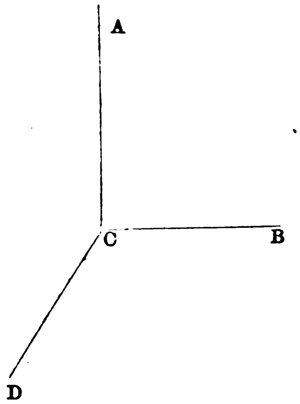
[56859.]—**Vertical Galvanometer.**—Placing a vertical detector on its back or at an angle increases its sensitiveness as a detector of current, but reduces its use as a measure and makes it nearly useless for detecting a lessened current, as the querist finds. In the vertical galvanometer the resistance to motion is that of gravity, the greater weight of the lower part of the needles; when laid on the back this is reduced to a minimum, and so there is nothing to bring the indicator back, while there is also little but friction to resist the pull of the current. In fact, when nearly horizontal the character of the instrument is entirely changed; if the two needles are nearly equal in power the system becomes "astatic," and can only be pulled across the wires by any current. If one needle is stronger magnetically the system obeys the earth's magnetism, like a single-needle common galvanometer, but under a lessened magnetic force to bring it to zero, and an increased electric influence tending to deflect.—SIGMA.

[56860.] — **L. and N.W.R. Compounds.**—There is no coupling on these engines; but they are fitted with extra large receivers, and blow-off valves in case of slipping.—REGULATOR.

[56860.]—**L. and N.W. Compound Locos.**—The engine you mention has no coupling rods, the absence of them being one of the points gained. But the two outside high-pressure cylinders being set at right angles, the engines of this class start freely enough. I have both seen the one you name, and also have frequently ridden behind similar ones working in this district. And the engines appear in every way most satisfactory.—INVICTA.

[56860.]—**L. and N.W.R. Compound Locos.** Although not connected with the L. and N.W.R., having seen several of the compound engines on that line, and also the "Marchioness of Stafford" at the Inventions Exhibition, perhaps I may be permitted to reply to "Crumby's" query respecting these engines. There is no coupling rod or other device to keep the low-pressure and two high-pressure cranks in any relative position. As "Crumby" may possibly know, the two high-pressure cylinders drive the trailing pair of wheels, and form one independent engine, and the low-pressure cylinder drives the centre pair of wheels, forming really a second engine, and each of these being able to run at what speed it can. Should the double cylinder or high-pressure engine slip, as this supplies the low-pressure single cylinder, more steam is sent into the eduction pipe (which acts as a receiver) than the large cylinder will take. The back pressure is increased, and helps to check the slipping, and the extra pressure on the low-pressure cylinder induces the centre wheels to slip also. If the low-pressure or single engine slips, it takes more steam than is supplied from the double engine; its own pressure, of course, drops, and the slipping ceases. In practice, each engine is found to control the other effectually, thus equalising the work of the two somewhat. I have myself noticed the effect before stated, when seeing a compound start with the Irish mail on a wet night, with slippery rails, the pressure on the single cylinder quickly reducing the slip of the other engine or h.p. cylinders, and aiding in getting the loco. itself off. I hope this explanation may give what "Crumby" wants to know.—W. H. THURLOW.

[56860.]—**L. and N. W. Compound Locos.**—The only connection between the high and low-pressure cylinders of the Marchioness of Stafford (and the same is the case with the other compound engines on this line) is in the rail, apart from the fact that the low-pressure engine receives its steam from the high-pressure exhaust. I should not think that the low-pressure crank is, as "Crumby" says, "at right angles to one high-pressure crank and opposite the other," for then there would be two dead points, should the engine stop with the opposite cranks on the centre—i.e., at the commencement or end of the stroke. The high-pressure crank being at right angles, is not the low-pressure crank midway between the remaining part of 360°? Thus: A C and C B being the rectangular position



of the high-pressure cranks, would not the position of the low-pressure crank be at D C, at an angle of 135° from either A C or C B? I am, of course, open to correction.—J. KEAN.

[56861.]—**Eccentric on Shaft.**—Will "S.L.N." advertise his address? I will communicate with him on the subject.—REGULATOR.

[56867.]—**Gas-Engines.**—I should much prefer that some one better acquainted with gas-engines than I am should answer W. Bundy's queries; but he is nevertheless welcome to my opinions, if he will take them for what they are worth. In regard to the 1st: The suction of the piston would be sufficient to charge the cylinder with gas; but it should be compressed afterwards. By exercising pressure a larger dilution of air can be employed, at the same time that the violence of the explosion arising from a less unequal mixture of gas and air is diminished. 2nd. An electric spark would ignite the gas, and numerous engines have been constructed in which the means of ignition was furnished by a battery; but a gas jet is cheaper and as effective. 3rd. Air is too bad a conductor for heat to be suitable for jacketing. 4th. The temperature would vary with the relative proportions of the charge; but it is often as high as 2,000° F. 5th. The mixture suggested would, I imagine, be useless.

Paraffin vapour and coal gas need air in order to explode, and the steam could not furnish the necessary oxygen, except at the temperature of dissociation, somewhere about 1,500° C. I, therefore, fail to see the reason of the suggestion. 6th. Yes; in so far as the pressure is greater.—J. H.

[56867.]—**Gas-Engines.**—To "J. H." AND OTHERS.—Yes; the charge is drawn in by the suction or partial vacuum due to the outstroke of the piston, in the Otto engine, for instance. And to your next, an electric spark has been used in the case of the Lenoir gas-engines; but it was not so satisfactory as the plan subsequently used—viz, that of a gas jet. Cooling the cylinder by means of air-current has already been tried and patented. The first form of the Bischopp engine had a somewhat similar plan of cooling by air. On the question of, say, three explosions on the one outstroke, I cannot see how it could be done, so can't give an opinion. What the temperature would rise to if the water supply was stopped I also can't say; but before it rose very high the engine would stop of itself. Paraffin oil would, no doubt, be nearly or quite vapourised. I may say I have seen paraffin oil decompose into a pungent smoke under such conditions by accident. The mixture you name of paraffin vapour, coal-gas, and steam would not explode; the two first would; whilst the steam could be admitted immediately after the explosion. But this has also been done. Coal-gas when heated with the air in a state of compression is advantageous; but this has long been done also. Heating the air also has been done successfully: when it is heated it assimilates better with the gas. —INVICTA.

[56868.]—**To Chemists and Metallurgists.**—The following method devised by Abel is given by Miller:—30 to 40 grammes of the metal are digested for three or four hours in the cold, with a smaller amount of a neutral solution of $AgNO_3$ than is necessary for dissolving the whole of the Cu. When the Ag is all precipitated, the residual copper is picked out, washed into the solution, dried, and weighed; the difference between this weight and that of the original mass giving that which has gone into solution. Now, if all the metal used was free of copper, the sole products of the reaction would be Ag and $Cu(NO_3)_2$; but if $Cu_2O$ was present, an insoluble basic nitrate would also have been formed, thus—

$$Cu_2O + 2AgNO_3 = Ag_2 + Cu(NO_3)_2CuO.$$

If, then, the mixed Ag and basic nitrate, left by decantation, be digested (with agitation) with a known volume of standard diluted $H_2SO_4$, a certain amount of the acid will be neutralised by the latter, and the amount left can be found by titration with standard alkali. By remembering that for every 98 parts of $H_2SO_4$ neutralised by the basic nitrate there were 143 parts of $Cu_2O$ (in the metal tested), the amount of the latter and its percentage can be calculated. As to the latter part of the query, I cannot speak positively, but should think it difficult, if not impossible, to get rid of As, Eb, &c., from such a large excessive metallic Cu by any ignition, however vigorous.—B. B.

[56869.]—**Grey Acetate of Lime.**—It is impossible to say what quantity of acetate of lime could be made from one ton of wood. The reason is, that if the wood be small, or very green, or slightly decayed, the quantity of acid would be very small compared with that obtained from a ton of large wood well seasoned. The subjoined is a tabular view of the amount and strength of the products obtained from the distillation of several varieties of wood, from which Marshall Reid can make his own calculations. I may say that the manufacture of acetate of lime in this country is almost a thing of the past, since American lime salts can be bought so cheap, and most of the works that did not make acetate of soda or acetic acid have had to close—that is, in South Wales:—

| Three hundred and thirty-six pounds of wood | Charcoal. | Charcoal per cwt. of wood. | Acid liquor. | S.p. gravity of acid liquor. | 1oz. neutralised grs. of bicarbonate potassa. | Dry acetate of lime produced. |
|---|---|---|---|---|---|---|
| Birch.......... | 84 | 28·00 | 180 | 1·029 | 9½ | 25 |
| Walnut ...... | 72 | 24·00 | 150 | 1·018 | 7 | 14½ |
| Birch, cut three years........ | 70 | 23·33 | 120 | 1·031 | 11 | 13 |

—CHEMICAL WORKS. —(Muspratt.)

[56871.]—**Whitewash.**—To make one that will not rub off, and will stand the weather, take freshly-burnt lime (Irish lime is very good) and soak for a night in as much water as will cover it. Then add buttermilk until it is the consistency of whitewash. Apply in the usual way.—B.Sc., Plymouth.

[56872.]—**Coil.**—The failure of this coil may arise from such causes as defective insulation, careless winding, or an unsuitable size of secondary. The secondary wire, in this case, seems to me to be too thick; the usual size being between Nos. 33 and 40, and always recommended to be silk-covered. The Daniell cell is also unsuitable. Try a bichromate.—BOBADIL.

[56872.]—**Coil.**—Your friend will require quite four times the amount of battery power he is now using for his coil, and he should use some double-fluid bichromate cells instead of the Daniells, as the former give a much higher E.M.F. It would have been better if he had not used so much insulation between the layers of his coil. Better try five or six double-fluid bichromate cells.—C. O. S.

[56872.]—**Coil.**— This correspondent does not state size of coil, or could advise better. Have made several powerful coils to work with two No. 2 Leclanché cells, as follows: Coil cheeks, 1½in. diam.; between cheeks, 3½in.; the usual bunch of iron wires for core, with brass tube for regulating strength of shock. Primary, four layers No. 18 silk-covered wire. Secondary, about 16 layers No. 38 silk-covered. It is not absolutely necessary to insulate each layer with paper. If whole be thoroughly soaked in paraffin wax, I should advise insulating primary from secondary with one layer of paper. The above gives powerful shock, with low battery power.—F. T. W. B.

[56872.]—**Coil.**—"Cymro" and his friend should read up some of the back numbers of "Ours" on intensity coils, and then try again; the present coil will be of no use. No. 28 c.c. is quite unsuitable for secondary; No. 36 s.c. should be substituted. Daniell's cells are not the batteries for coils; bichromates, Bunsens, or Groves are the proper ones to use on account of their vastly superior E. M. F. Nothing is said about a condenser, without which the spark will be a small one, and I expect the blotting-paper insulation is too clumsy between the secondary layers. The secondary also may not be properly insulated from the primary by a tube.—B. H.

[56872.]—**Coil.**—"Cymbro's" complaint as to his friend's coil leaves very little room for suggestions. The coil seems to have been built properly, and the battery power to be sufficient. All that I can say is, Be sure that the junctions of the wires with binding screws, &c., are clean, well made; if they are so, then I am afraid that at some spot or other in the secondary wire there is a break, occasioned in winding, and this may happen even with the greatest care. Is "Cymbro" able to tell us any more about the coil? Then perhaps I may be able to help him. He makes no mention of a piece of soft iron within the coil. I should suppose that he has it, as I don't know whether he works the contact breaker from a separate smaller magnet.—J. KEAN, Northampton.

[56874.]—**Estimation of Magnesia.**—This substance is usually precipitated as ammonium magnesium phosphate, and subsequently ignited, which converts the double salt into magnesium pyrophosphate, thus—

$$\begin{array}{ccccccc} 2AmMgPO_4 & = & Mg_2P_2O_7 & + & H_2O & + & 2NH_3. \\ 274 & & 222 & & 18 & & 34 \end{array}$$

The residue, after ignition, contains 36·036 per cent. of MgO.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56875.]—**Thymol.**—This aromatic alcohol is stated not to separate from its solution in alcohol on addition of water; but there are two varieties of thymol, both being methyl-propyl-phenol, one probably containing normal and the other isopropyl; and it is quite possible that one of them separates, although the other does not. Try warm water instead of cold, and add the water slowly to the alcoholic solution. Which variety of thymol are you using?—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56876.]—**Reflectors.**—An astronomical friend some time since was asking my advice on the question of a tube for a 9in. reflector. As he desired to make it himself, I sketched him out an easy plan. The tube is made of wood in straight staves jointed up like a barrel. To hold it together stout brass bands with screw eyes for tightening up are used, whilst to stiffen it, three wrought-iron rings are placed inside and let in flush with the inner surface of the tube. Arrangements for ventilation were not made in the tube, but the mode of construction renders such very easy if thought desirable. The outside being polished and the brass bands got up bright and lacquered, the tube looks as well as it is useful. In my opinion it is superior to a riveted-up iron tube, besides looking better and being easily made by anyone who can use carpenters' tools.—INVICTA.

[56877.]—**Coil Winder.**—An automatic coil winder has been figured in these pages—I cannot say exactly how long since; it might be a couple of years.—Os.

[56878.]—**Mineral Water.**—I have no special knowledge as to the manufacture of mineral waters, but I am of opinion that it would not be possible to use acetic acid instead of citric acid.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56878.]—**Mineral Water.**—Most probably the citric acid is used for making lemonade, and it is the only acid suitable for the purpose, as it happens to be extracted from lemons and other similar fruit. Acetic acid is the acid which is contained in vinegar, so that if your customers like vinegar and water in place of lemonade, by all means use it. I may as well also mention, for the benefit of those whom it may concern, that lemonade, gingerbeer, and such like drinks are not mineral waters, as there is nothing mineral about them; the proper term for these effervescing liquors is aërated waters. —Os.

[56880.]—**Pyroligneous Acid.**—The most useful size of cylinder is 6ft. by 4ft. in diam., thickness of metal ⅛in. The doors: some are hinged, some the same as gas-retort doors, only no screw but wedges between the cross-bar and door: the doors are luted. Lute composed of sand, clay, lime, mixed with water and a little pyroligneous acid. But I would rather use ovens than cylinders. I find them more useful for mixed wood. Our ovens are 6ft. by 6ft. by 4ft. 6in., made of ½in. boiler plates. Each oven has two boxes, the one in at work, the other being filled ready for changing (each day). The condensers are made of copper, from three to four pounds per super. foot of the sheet; and ours vary from 12in. to 9in. in diameter. But I find 10in. diameter and 35ft. long (all condensers going into one lump and one return waste condenser the same length), the best working arrangement of condensers. About the stills I cannot say anything, not knowing the quantity of wood or the number of cylinders or ovens in use, or to be used. I shall be happy to give "Chemist" any further information, if required, in naphtha, acetate of lime, acetate of soda, or acetic acid (pure acetic acid).—CHEMICAL WORKS.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

Since our last, "Glatton" has replied to 56031, 56039, 56068, 56090, 56141, 56154, 56188; "Invicta," 56540.

DR. W. COHN recently gave some figures which he obtained from a works in upper Silesia, where thirty coke ovens have been altered for the condensation of by-products. At those works 100 kilogrammes of coal yield 3 per cent. of tar, and 1 per cent. of ammonium sulphate. The thirty ovens coke daily 50,000 kilogrammes of coal. The price on the spot for tar is 4½ marks (1 mark equal 1 shilling) per 100 kilogrammes, and for ammonium sulphate 25 marks per 100 kilogrammes. It has been found that the treatment of the ammonia water costs for fuel, labour, &c., 9 marks per 100 kilogrammes of ammonium sulphate produced, so that the selling price being 25 marks, the profit is 16 marks per 100 kilogrammes.

# QUERIES.

[56881.]—**Observatory Dome.**—I should be obliged if "Invicta" would give me a few hints as to the construction of a light, revolving dome, 8ft. diameter, for a small observatory? I thought of a framework of angle iron, covered with sheet zinc, but am in a fix about it. —W. T. C.

[56882.]—**Catalogue for Lending Library.**—I should be obliged to anyone for telling me how to arrange a catalogue for a lending library, how to class the books, and which class to put first, or any information relating to the above subject?—LIBRARIAN.

[56883.]—**Portrait Photography.**—Will someone kindly help me in this difficulty? A few weeks ago I could get good negatives, now I am unable to do so, though I still keep to the same plates, viz., Fry's, and their sodic sulphite developer, which they supply. My apparatus is a ¼ Le Merveilleux. My plates require extraordinarily quick exposures to what they did; one second being too much in dull weather with ordinary plates. I find this difficult with a drop shutter; but when exposure appears correct they do not develop with sufficient density, and require no time in the fixing solution. How do plates perform that are fogged by damp or light? I now fail to get the white appearance at the back after development.—SEE BEE.

[56884.]—**Gramme Dynamo.**—Will Mr. Bottone kindly state the length required, and diameter in round section for the four field magnets of a Gramme dynamo having a Pacinotti ring 6in. in outside diameter, and 4in. long? Also required the depth of channels in ring, and substance of the ring body? This information will oblige—LITTLE DORRIT.

[56885.]—**Potato Cleaning.**—Will "Invicta," or any other reader tell me how I could make a machine to clean pototoes for the table—40 or 50lb. at one operation, or tell me if there is such a machine in use anywhere?—SUBSCRIBER.

[56886.]—**Model Boiler.**—Will someone kindly describe the best form of lamp to heat a vertical boiler of the following dimensions, by means of methylated spirit? Boiler, 8in. by 5in., with internal firebox 4in. wide by 3in. high, centre flue 1¾in. diameter. Spirit burnt in an open vessel in firebox raises steam quickly, but makes an awful smell. Gas is not available, and a fire is objectionable indoors. The boiler is made of copper, 18 B.W.G. throughout, all joints well riveted and soldered. Will 30lb. be a safe working pressure? I intend making the engine with cylinder ¾ bore and 1½ stroke. Have I heating surface enough for a cylinder 1in. bore?—F. C. P.

[56887.]—**Drying under Pressure.**—I have a substance to deal with that is capable of being dried very hard at 60deg. or 70deg. Fahr., but if this is exceeded it all cracks. This being very slow, I wish some of your readers could give me a plan whereby I could try drying it on a small scale under pressure; or any suggestion will be thankfully received.—SOUTER.

[56888.]—**Bicycle Turning.**—In turning in a circle, with the handle-bar of my bicycle turned round as far as it will lock, I find that both wheels make true circles to one centre. How can this be accounted for, with regard to the small wheel, which is kept rigidly by the backbone and its own forks, in a plane always at an angle with the driving wheel?—J. R. T.

[56889.]—**Protosulphide of Iron.**—Can any of your readers give me a good method for making protosulphide of iron (FeS) on the large scale, say one or two cwts. at a time?—C. D.

[56890.]—**Filtering.**—I want to filter considerable quantities of liquor, to hasten which I wish to produce a vacuum beneath the filtering medium. I know, of course, that this can be done by means of a suitable pump, but wish it possible to do it more cheaply by means of one of the well-known vacuum jets. Any reader who has worked with these would oblige me by giving a hint or two as to his experience with them.—C. D.

[56891.]—**Shocking Coil.**—I have finished making a shocking coil. I have two rows of primary, No. 18 c.c. and 12 rows of secondary. It is insulated with paraffin waxed paper, on an electro-magnet contract breaker, fixed to the base, and I cannot get any shock from it when I fix a pint Bunsen battery to it. Should I have another battery? Will any brother reader oblige by putting me right?—I. O. G. T.

[56892.]—**Tricycle Chain.**—The chain of my tricycle makes a loud, rattling noise when I am riding on rough roads. Will some reader tell me the cause, and how to correct it?—C. A. W.

[56893.]—**Astro.**—I am much obliged to "Fellow of the Royal Astronomical Society," and Mr. Saddler, for their answers to my query about Stellar Parallaxes, Binary Stars, place of Spica, &c. Would either of these gentlemen kindly inform me whether the star 61 Cygni is not a binary, as it is not in their lists, and also as to the smallest star visible in the daytime, with telescopes of various sizes? I have a 4¼in. refractor, and should be glad to know how faint stars I could see with that? What is the period of the shortest known double star?—M. ARKWRIGHT.

[56894.]—**Oils.**—Can any correspondent enlighten me on the best and cheapest method of thoroughly purifying and clarifying lubricating oils (mineral and vegetable) and grease mixed together, which have become thick, black, and dirty by use?—ONE IN A FIX.

[56895.]—**Cutting Wards of Keys.**—How is the above done in the shops? I cannot find any information in back numbers. I have occasionally to cut wards in field padlock keys, and find the ordinary way with a flat file, very tedious and troublesome. Could they be cut quickly on lathe, with circular saw, or small emery wheel? Directions would much oblige.—AGRICULTOR.

[56896.]—**Loco. Slide Valves.**—Will someone kindly tell me some methods of setting valves?—also of finding the lead? Also, if possible, inform me how to read and understand indicator diagrams?—A. M. P.

[56897.]—**Organic Chemistry Examination.**—Will any of our readers who sat for the examination in Practical Organic Chemistry, advanced stage, at South Kensington, kindly inform me what constituents were found in the substance given for analysis?—W. O. T.

[56898.]—**Naphtha.**—Can any reader inform me what causes the smell I sometimes perceive from some naphtha works about a mile away? Whether it is due to the escape of any gas, and if so, what gas? I should like to know of any books treating on the manufacture of naphtha.—F. S Sc.

[56899.]—**Boiler.**—To "INVICTA."—I have an egg-shaped boiler shell, 32in. long, 13in. diameter, 3-16in. plate, the end plates welded. Will you kindly inform me if the above can be made suitable to drive an engine 2½in. diameter, 5in. stroke, also the best way to supply the boiler with water?—C. J. F.

[56900.]—**Locomotive.**—To MR. STRETTON.—I was having an argument with a friend the other night, concerning the cost of a locomotive railway engine, who informed me that the average cost of same amounted to from £2,500 to £3,000. Is this correct?—if not, will you kindly let me know the average cost of an ordinary engine?—W. E. S.

[56901.]—**Irish Degrees.**—Can any of our readers inform me what colleges or universities in Ireland grant the degrees of LL.B. or LL.D., and if they require candidates for the same to attend lectures or classes there, before offering themselves for examination?—STUDENT.

[56902.]—**Electric Lighting on Trains.**—Last autumn some suburban trains on the G E.R. were lighted by electricity. A Tower high-speed spherical engine, coupled to a dynamo, were placed in a box on the top of the locomotive boiler barrel, and supplied the power direct, without any secondary battery, to the incandescent lamps in the carriages. When at Liverpool-street terminus a few weeks ago, I did not notice any train so fitted. Can anyone kindly say if this system is still in use on the G.E.R., or elsewhere? Perhaps it is only discontinued during the summer, or if given up entirely, is it because the light going out when the locomotive is disconnected from the train was considered a fatal objection to its general adoption. Any information respecting this will oblige.—W. H. THURLOW.

[56903.]—**Steam.**—Will some reader of the "E.M.", give me an answer to the following questions, asked at an examination on steam? Explain the difference between a non-condensing engine and a condensing engine? Show, by a diagram, that more work is obtained from a given quantity of steam in the latter class of engines. 2. Steam is admitted into a cylinder, 32in. long, at 40lb. pressure above that of the atmosphere (viz., 15lb. on the square inch) and is cut off at 1-5th of the stroke. The area of the piston being three square feet. Find the work done in one stroke, by dividing the stroke into five equal parts, and considering the pressure in each of the latter four parts to be the mean of the pressure at the beginning and end of same?—GOODEVE.

[56904.]—**Problem in Algebra.**—Can any of our mathematical correspondents help me with the following problem?—Prove that the coefficient of the middle term of

$$(x + a)^{4n} = 2^{2n}\frac{1.3.5\,7\ \ldots\ldots\ (4n-1)}{1.2.3\ldots\ldots\ldots\ 2n}$$

The denominator comes out all right, but I cannot get the numerator. If someone would help me with it, I shall be much oblig-d.—BUNSEN.

[56905.]—**Mal de Mer.**—Can any reader speak from personal experience, or by referring to the *British Medical Journal*, of Oct. 24th, 1881, p. 730 (which I cannot obtain) as to the efficacy of the alkaline bromides, in preventing seasickness? The passage referred to, I believe, recommends 60gr doses for two or three days before sailing; the ordinary dose is 2gr. to 6gr. I should be glad to hear of any medicine or treatment which has been found useful.—MON.

[56906.]—**Deed of Gift.**—Would Mr. Wetherfield please say if a deed of gift requires a stamp?—if so, of what value? Also, would he give a general idea of the wording to be legal?—X X. X.

[56907.]—**Electro Magnetism.**—I see by various scientific books, that an electro-magnet can easily be constructed to lift (and therefore I presume to move, if necessary) from one to two tons. Can any of your readers inform me whether there is any cheap way of keeping up the supply of electricity required, and what would be the best way of doing it, as this part appears to me to be a very expensive item?—ROMEO.

[56908.]—**Caloric Engine.**—I am having a Caloric engine constructed, and am now in a difficulty. I find the heat shrinks up the packing (asbestos) and causes leakage, and consequently loss of power. The loss of power also sustained by the engine is very great in working the pump, which has to keep up the supply of air. How are these difficulties to be overcome, and what packing should be used? Perhaps "Invicta," who, I know, is always ready to succour the distressed, or some other kind friend, may help me to solve this problem.—ROMEO.

[56909.]—**To Mr. Bottone.**—I am making a dynamo on the Gramme principle, with eight malleable round field-magnets, four at the top and four at the bottom; they have flanges ¼in. thick at each end (like cotton reels in appearance) the body of these F.M.'s is 1⅜in. diameter; length, including flange ends is 4½in. I intend to bolt pole pieces to these eight cores, so as to form one electro-magnet system. Before making the pole pieces, I should like to ask Mr. Bottone what would be the most suitable size of armature for this arrangement. I should mention that the fields are arranged in circular form, so as to give an even magnetism to the pole pieces; they will be wound in series form; the four top ones alike, the four lower ones also alike, only in different direction to the upper bars. If Mr. B. recommends a ring with cogs, will he kindly indicate the depth they should be, and the substance of the ring body in malleable iron.—SUBSCRIBER FROM No. 1.

[56910.]—**Flame.**—I have understood that the luminosity of a flame is caused by the incandescence of particles of carbon, which the combustive material contains, which I do not in the least doubt; but what becomes of the said carbon in an atmospheric gas burner, is it consumed?—The colour of the flame is that of pure hydrogen, the result is $CO_2$ not $OH_2$, I suppose.—AYLWARD.

[56911.]—**Writing on Glass.**—Can any obliging reader give a recipe for an ink suitable for writing fluently on glass, or else for writing on paper, to be transferred on glass?—CH. R.

[56912.]—**Jablochkoff's Battery.**—Will anyone kindly give me instructions for making the above? It was described in the "E.M." of the 5th inst.? Is it patented? How many cells required for a 2½-c.p. lamp?—J. H. G.

[56913.]—**Weatherproof Paint for White Marble Gravestones.**—Will some of your readers kindly inform me of the best mixture, and the best method of applying a paint to engraved letters on a white marble gravestone, that will withstand the weather for several years? The paint that has been used up to the present time is constantly washing off, and wants renewing every few months, if we wish it to look respectable. A few hints on the above would be gladly accepted.—E. HOLT.

[56914.]—**Socket Joint Making.**—Can anyone tell me how to make a cement that will make faulty socket-joints good and perfectly tight in hot-water apparatus, and how much of the old borings require to be got out, and how to apply the cement? I may add that the joints have been made and caulked with iron borings, and some leak very much, and as they are fixed they cannot now be got at to caulk, and those faulty joints are on the ground floor of a three-story building. So that the weight of the water above is upon them? Shall be glad of a sure cure.—ANXIOUS.

[56915.]—**Gas-Engines.**—To "J. K. P."—If it is not asking too much of you, and you are not taking out provisional protection for your new gas-engine, would you please send drawing and particulars to the "E.M.," as it is hardly possible for me to see your gas-engine, because I live in the country, and there are other circumstances which prevent me from seeing it.—THEO.

[56916.]—**Telescope Eye-tube.**—Will some correspondent kindly give me a description, with sizes and sketch, if possible, of eye-tube, suitable for a 6½in. reflecting telescope, with rack and pinion movements? Also the number of threads to the inch used for fitting eyepiece to eye-tube?—G. R.

[56917.]—**Plaster Ceiling Centres.**—I should much like to ask readers of your valuable paper, if those plaster ceiling ornaments, which are to be seen in some houses, are made out of moulds or stamped out by dies, and to obtain some explanation of how it is done? Does hair, straw, wool, &c., enter into the composition of the liquid plaster? An address or two of the best plaster of paris ornament makers would also be welcome.—THO. DULLYMAN, Maindee.

[56918.]—**Gas Engine.**—I should be obliged if "Invicta," or any other competent person, will state the proper diameter of bore of cylinder, and length of stroke of a two-man nominal power, simple non-compression gas-engine, also the best size and weight of flywheel to suit it?—CHIP.

[56919.]—**Electrical Weather Vane.**—Will some correspondent kindly explain to me, through these pages (with illustrations) how I can connect a weathercock electrically? As the vane is in the garden, I wish to connect it with an indicator in the hall.—H. POLLITT.

[56920.]—**Locomotive.**—Will some kind friend please inform me how often a locomotive boiler should be washed out when in regular use, and how the boiler should be treated in every way, how often should they be new tubed, &c.? The above would greatly oblige.—S. S.

[56921.]—**Heat for Workshop.**—Would some reader kindly tell me how to construct a lamp for a workshop, to supply the place of an ordinary gas-jet? It is not possible for me to have gas. I have tried the spirit-lamp, but cannot obtain the necessary heat for hardening drills, tools, &c., and one cannot always have a fire alight, especially summer weather. Any information will be thankfully received.—P.

[56922.]—**Twine.**—What kind of machines are used for making fine twine, such as used by druggists, grocers, &c., and how is it polished?—who makes the machines, &c.?—TWINE.

[56923.]—**Bleaching Shellac.**—In No. 991 of the "E. M.," for March 21st, 1884, there is a process given for the above, before trying which, I should like to be enlightened upon the following points, viz.—(1) It says "the liquid is boiled for a few minutes, and, while hot, a wooden air-tight cover is cemented on the vessel." What cement is used for this purpose? (2) How am I to tell when I have added enough dilute sulphuric acid to decompose "the clear filtrate"? (3) What is "glycerol?" (4) And would it be necessary to pull it (the shellac), should I require it very white? I have plenty of the best button lac at hand, and would like to do my own bleaching, as I use about a half-cwt. a week. Perhaps some of "ours" will kindly give the information required, or give some other process which is simple, cheap, and reliable.—J. L.

[56924.]—**Logwood and Gall Liquors.**—What instrument can I use to test the strength of each of the above after boiling? What is the difference in the strength of, say, 1lb. logwood, and 1lb. logwood extract? What is the best antiseptic (odourless) to use for preventing ink from turning mouldy?—J. L.

[56925.]—**Draught in Chimney.**—I have heard that by hanging a chain with a knot tied at its lower end, or a rod with a ball at one end, down a chimney, it will materially improve the draught. I shall be much obliged if any of your readers can give me the following informative on the subject:—(1) Should the knot or weight be near the top or bottom of the chimney? (2) The relative size of knot or weight to the chimney? (3) Does it make any material difference in the draught? (4) What is the principle on which it acts? I have a chimney 60ft. high, by 2ft. 3in. diameter for a boiler, with grate area of 18 square feet, and the draught is so sluggish that I cannot burn more than 10cwt. of coal in nine hours. I thought once of forcing the fire with a fan draught; but if this chain or ball arrangement will do, it is much simpler.—W. HOSKEN.

[56926.]—**Leaky Tank.**—I have a large wooden tank in which I keep a strong solution of soda-ash (30's) for cloth scouring purposes. I find that the alkali is slowly attacking the wood and causing it to be leaky. Will any contributor kindly inform me as to how I can best prevent this?—R. H.

[56927.]—**Co-ordinate Geometry.**—Having some time ago commenced the study of this science, and made some advance in it, I obtained a more advanced book, which treated on another method—that of trilinear co-ordinates and abridged notation. This latter method seems to me much more complicated and difficult, and I would wish to be informed if it would be worth while to undertake the task of mastering it for any special advantages it possesses over the other method, particularly as it seems to me that it is the ordinary system of co-ordinates that is adapted to the calculus.—Alpha.

[56928.] — **Resilvering Mirrors.** — What is the simplest and best way to resilver the concave mirror of a microscope? I have seen elaborate directions for silvering specula and large mirrors. I hope somebody will give me the necessary directions, solutions, &c., for resilvering small mirrors. I have two which require to be done, each about 1½in. in diameter.—Pathologist.

[56929.]—**Cork - cutting Machine.**—Will some friend kindly inform me a little in making the above machine, to cut from ⅜ to about 3in.? I have made a frame of wood 3ft. 6in. long and 10in. broad, and the sides 4in. deep. Will you kindly say what size wheels to use for turning the chucks, and the best way to shift the knife to any size or taper?—X. Y. Z.

[56930.]—**Three Problems.**—Problem 1. In three events where the odds are three to one against the first, five to one against the second, and seven to one against the third: what are the odds of winning some two out of the three? Problem 2. In three events where the odds are three to one against the first, five to one against the second, and seven to one against the third: what are the odds about winning two in succession? Problem 3. An event has to be decided by the winning of two heats out of three; the odds against the first is three to one, against the second, five to one, and against the third, seven to one. What are the odds about winning some two out of the three? Will someone kindly say how to calculate the above and give a rule proving the correctness of same—and oblige?—Perplexed.

[56931.] — **Bearing Grease.** — Presuming that "Essar" will give me a recipe for making this article, I beg to thank him beforehand. I wish to make the grease for my own use, at a cost of twopence per pound, for hot necks.—Inquisitor.

[56932.]—**To "M. I. C. E."**—Given a sphere 12in. diameter; it is required to draw a diametral hole through it, of such a size as to reduce the contents of the sphere by one half. I make the diameter of the hole, an arithmetical mean between the side of the pentagon inscribed in a great circle of the sphere, and the arc of the circle, of which such side forms the chord, but this is apparently only a chance and merely approximate coincidence, and I am anxious to know if any precise formula can be given. Here is a pretty result which I have never seen in print. From the hemisphere G A H, cut the sector E A F C, consisting of segments of height A D and cone of height D C together: this sector cut out leaves the socket E G C F H. Then as sector to socket, so is A D to D C. I think "M. I. C. E." will be able to draw the figure from the description. C being centre of circle; G C H, a vertical diameter of the sphere, and E D F, the line parallel to it representing the base of the cone: A D C, at right angles to E F and G H, being the axis of cone.—A. S. L.

[56933.]—**Mechanical.**—(1) Can any of the readers of this valuable paper inform me how to produce those moonlight effects in panoramic scenery? I am at present painting some scenes, and want to break monotony of entertainment by showing a scene representing day and then changing it to night. Any information how to manage these moonlights, or churches and palaces lit up, is kindly solicited. (2) My intention is to have the scenes all on one roller, but instead of running them across as most panoramas, I wish to roll them up. Can anyone suggest a frame to carry same, one that will be substantial, yet one that can readily be put together? A large gilt frame will stand in front of scene, bottom of which will be 2ft. from floor; length of scenes 15ft., height of same about 9ft. I have "E. M.'s" from 1872, to which I can refer if there is anything; if not, any information will be acceptable.—J. P. H. B.

[56934.]—**File Cutting Machines.**—Can any reader of the "E. M." give any description about the cutting machines, or the numbers of the patents, if such have been patented, and dates?—File Machine.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette*.—Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists, London."—Also makers of Epps's Chocolate Essence.

## ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, June 24th, and unacknowledged elsewhere :—

G. Birch and Co.—T. Barker and Co.—W. H. Tulloch.—W. Nolan.—J. A. Campbell.—Foster and Williams.—H. W. Williams and Co.—J. K. Smythies.—Optical.—J. T. Gent and Co.—J. Calvert and Co.—W. Bradbury.—W. T. Glover and Co.—R. W., Newcastle-on-Tyne.—Conductor.—Sceptic.—D. K. M.—Excelsior.—A. B. C.—P. W. Stanley.—Accumulator.—An Old Subscriber.—D. W.—B. J. Hopkins.—John White.—A. Lester.—Lynton.—H. H.—Charles North.—W. P.—D. Booth.—Lever.—J. E. Gore.—St. Pancras.—J. H. Bowman.—W. E. T.—A Fellow of the Royal Astronomical Society.—F. A. Robinson.

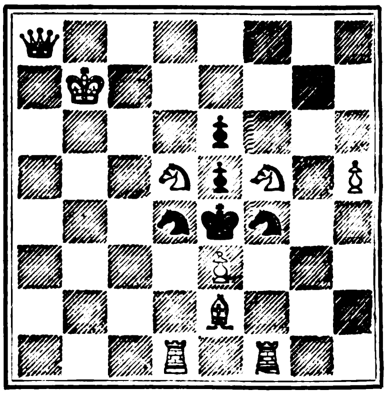
A Clerk. (If your physician can do nothing for you, how can you expect strangers to supply you with a remedy for your failing sight? You should consult an ophthalmologist.)—Creeping. (If your physician has advised you to try electricity, he will also tell you what appliances are required. You will find descriptions of such appliances in back numbers; but no one can recommend anything without knowing the nature of the "nervous trouble.")—Wildbank. (What difference can there be?)—Hugh. (It is constitutional. Any druggist will make you up a suitable astringent lotion, and for the rest you must do what is possible to improve the general tone of the system.)—R. E. N. C. (You do not seem to have read the letters on the subject. See p. 57.)—Edward Hawks. (How can readers criticise unless you supply a description of the new brake? That sent in is merely an indication of the principal features. Details are needed for any useful criticism.)—S. Barron. (Too late for last week. You must "relax" them by placing them on blotting paper laid over damp sand, or by attaching to pieces of cork and floating in a vessel of water covered with a damp towel. They must be afterwards treated with preservative solution and mounted in a proper manner. If you cannot see back volumes procure Dr. Knaggs's "Lepidopterist's Guide," J. Van Voorst.)—E. Williams. (If you mean preparations for freezing water, see the indices or answers to "An Inquirer," p. 312. The water or mixture to be frozen is put into a vessel of thin metal and surrounded by the refrigerating materials.)—L. B. (Procure the prospectuses of the Birkbeck Institute, Bream's-buildings, W.C.; the Working Man's College, Great Ormond-street, W.C.; and the Finsbury Technical College, Cowper-street, E.C. Laboratory practice is absolutely necessary, but it would be advisable to pass in the elementary stage before attempting the laboratory work, as it is only evenings that you have at liberty.)—Smasher. (We are afraid you must apply to the Master of the Mint for the list. Many of the coins made there are for colonies and dependencies.)—Lotus. (It is an hydrometer for taking the specific gravity of liquids; but of what pattern it is impossible to say from your description. They are called areometers, alcoholometers, densimeters, and various other names, according to the special purpose for which they are used. A dealer in such instruments would be able to give it a definite name on sight.)—Throat-hoarseness, &c. (No relief can be expected until a skilled diagnosis has been made. Probably considerable injury has been done by the vast quantity of medicines.)—A Subscriber to the "E. M." from Commencement of the Present June. (All particulars of the kind can be obtained on application to the Secretary of the Pharmaceutical Society, Bloomsbury-square, W.C.)—A. J. Hawkins. (You must, at least, give us some idea of how long ago.)—Asterisk. (If you procure the Rules, price 6d., you will have all the information you need. They are sold at the Sale Office of the Commissioners of Patents, Cursitor-street, W.C.)—W. L. B. (You can only blow them to pieces with gun-cotton, dynamite, or gunpowder. You will find a good deal of information on the subject in Vol. XXVIII., pp. 180, 229, 379, 476. See Hints No. 5.)—G. Andrews. (See indices. Do you mean a Fahrenheit thermometer, or a mercurial barometer, which has nothing to do with Fahrenheit. If the latter, you have merely to fill the tube with mercury, put your thumb on the top, and invert the end beneath mercury in a little cistern. Then remove your thumb, and the pressure of the atmosphere will support the mercury in the tube to a height of between 27 and 32in. Make a scale in inches and tenths, and fix it by comparing with a standard instrument. A tube 3ft. long is more than sufficient.)—Rover. (You are correct when you express the opinion that your idea will not work. Neither will the new one. See Dircks's "Perpetuum Mobile," or the back volumes.)—One who Would. (There has been a good deal about microscope construction in back volumes, but our columns are always open to those who will tell their fellow-readers how to make philosophical apparatus cheaply. If we may judge from the number of queries sent about it, many readers would like to know how to make a spectroscope for 5s., as mentioned recently at the Society of Arts. A query appeared on p. 243, but so far has not been answered.)—A Copper. (They are chosen from the ranks, except under very special circumstances. The pay is good.)—Alpha. (For tempering spiral springs see p. 519, No. 1,011, where you will find an illustration of the "cradle.")—Senex. (Surround the type with a frame higher than the surface of the letters. Fill up with melted wax to about a tenth of an inch from the top of the letters, and then pour the mixed plaster of Paris on. Level off when nearly dry.)—C. M. (Prof. E. C. Pickering, Harvard College Observatory, Cambridge, Mass. The other is professor at the U.S. Naval Observatory.)—T. R. (Ohm is the unit of resistance, volt the unit of electromotive force. See any textbook of the subject.)—J. R., Shoreditch. (See any of the indices, or recent back numbers.)—Evan, an L.M. (You can obtain all particulars on application to the captain of the Steam Reserve, at any of the Government Dockyards.)—Allegro. (See recent back numbers, and the last two volumes.)—A Constant Reader. (See the indices for a variety of methods of destroying blackbeetles. On p. 181, No. 1022, a correspondent said he had found red-lead and flour the best bait for cockroaches and crickets.)—A Five Years' Subscriber. (The pressure is the same per square inch. How could it be otherwise? 2. So far from being a bad plan, something similar is used on the underground railways. 3. If you are a five years' subscriber, what have you done with Vols. XXXIII. and XXXIV., which contain some excellent lessons in mechanical drawing? For books, see the publishers' lists.)—John Robertson. (We believe it is published by Ward, Lock, and Co., Stationers' Hall-court, E.C. See Hints, No. 5.)—Samolet. (Probably it would do; but much depends on the clay. See p. 180, Vol. XXVII., or Reid's book on the manufacture of Portland cement, published by E. and F. N. Spon.)—St. Pancras. (Too vague. There is scarcely a family that has not "money in Chancery"; but till something more definite is ascertained you would waste your time in pursuing a claim.)

## CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

### PROBLEM DCCCCXLV.—The Four Knights.

*Black.*



*White.* [9+5

**White to play and mate in two moves.**

Solution to 943.

| *White.* | *Black.* |
|---|---|
| 1. Q-Q 4 | 1. Anything |
| 2. Q, Kt., or P mates. | |

(Five variations.)

### NOTICES TO CORRESPONDENTS.

Correct solutions to 942 by H. Culmer, Streetgate (a capital problem), J. A. Miles, (very good and difficult), A. A. E. Lecluse (exquisite) and F. A. Vincent.

To 943 by J. A. Miles (a good problem), H. Culmer, Streetgate (very easy), Rev. W. Anderson (Old Romney), A. A. E. Lecluse (an easy key move), S. L. Chivers, F. A. Vincent, A. W. Orr, T. L. Robins, and F. O'N. H. (neat).

To 944 by E. S. Streetgate and O'N. H. (restricted).

J. A. Campbell.—If 1 $\frac{\text{K-Q B 7,}}{\text{R checks}}$ if 1 $\frac{\text{R-Ksq (ch)}}{\text{covers.}}$, how does Q mate, and where? If 1 $\frac{\text{R takes B}}{\text{K takes R}}$.

G. T. Stringfellow and T. L. Robins.—The problem is quite sound. In reply to 1 $\frac{}{\text{K takes K P}}$, 2 $\frac{\text{Kt-B 2}}{}$ is the correct play.

F. A. Vincent and J. H. Blake.—Thanks for games.

**Holloway's Pills.**—These pills purify the blood and act most powerfully on the liver, stomach, kidneys, and bowels, thus giving tone, energy, and vigour to the whole system. They are wonderfully efficacious in all ailments incidental to females, young or old, and as a general family medicine are unequalled.—[Advt.]

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, JULY* 3, 1885.

## ELECTRICITY AND "DUST."

IT will be remembered that at the Montreal meeting of the British Association Prof. Oliver J. Lodge was requested to deliver one of the evening discourses, and chose for his subject "Dust," a term apparently definite, but in reality covering a very large variety of organic and inorganic substances—the "floating matter of the air," as Tyndall puts it; though, as Prof. Lodge says, it should really be "sinking," for the dust floats only because it is prevented from sinking bodily by the currents of the atmosphere. Foreign particles in our aërial envelope, whether solid or liquid, are not floating, but slowly settling down, and where the air is still they lodge on any convenient spot, as the housewife knows. We recognise terrestrial dust and cosmic dust, and scientific men have been engaged for some time in studying the question whether the latter could be collected, its nature ascertained, and its amount calculated. As regards the latter point, we are not at present interested; but we are about to describe a remarkable instance of the rapid manner in which pure science is nowadays converted into applied science, and that in connection with the removal of dust from the air. Mr. Aitken, some time ago, showed that every spherule of mist, every particle of fog, must have condensed itself round a minute solid dust atom or nucleus, and it follows, then, that if dust could be removed from the atmosphere there could not well be a fog. The simpler methods of removing dust from the atmosphere are well known: it may be strained out by cotton wool, or allowed to settle by confining a portion of the air; it can be "washed out" by condensing vapour several times, it can be calcined, and, as Prof. Lodge has shown, it can be "settled" by discharging electricity into it. Tyndall's experiment of calcining air, as he called it, consisted in holding a hot body beneath a sunbeam, when dark interspaces of dust-free air make their appearance. A spiral of platinum wire placed in a bell-jar and made hot shows this phenomenon well, and Prof. Lodge and Mr. J. W. Clark proved that the clarification of the air was not due to combustion or evaporation, while Lord Rayleigh has demonstrated that a cold body is equally effective, as it produces a descending dust-free stream of air. A discharge of electric sparks through a dust-laden atmosphere will cause the dust to settle—a phenomenon which formed the subject of research by Prof. Lodge and J. W. Clark, with practical results which will be seen by-and-by. At the Montreal meeting, a continuous series of sparks were sent through a bell-jar filled with magnesium smoke, and in a very short time the air in the jar was cleared; similarly, when the jar was filled with steam, electrification caused the globules to aggregate into mist and fine rain, which rapidly fell. These observations are original to Mr. Clark and Prof. Lodge, and the latter, towards the conclusion of his lecture, advised his audience to "stick to the pure science, and the applications will take care of themselves." The truth of that dictum has been verified in a remarkable manner, for Prof. Lodge's lecture was read by the head of a firm of lead smelters in North Wales, who conceived the idea that if electricity could do so much in a laboratory experiment, it might be made to do something useful on a large scale. Most of our readers will know that in lead-smelting works the greatest difficulty is to deal in a satisfactory manner with the lead fume, or the volatilised lead, which passes off from the furnaces. Long condensing flues and chambers are employed; but even with the best arrangements a good deal of lead escapes to poison the atmosphere and to the loss of the manufacturers. At Bagillt, in North Wales, at the works of Walker, Parker, and Co., the flues and chambers have a total length of two miles, and even with that enormous length the purification of the vapours from lead is far from complete. Mr. Walker, having read the lecture delivered by Prof. Lodge, put himself into communication with that gentleman, and his scheme appeared so feasible that it was determined to make a practical trial. A large-sized wooden flue was constructed out of casks, and fitted with windows at opposite points throughout its length, so that the "fume" could be readily examined as it passed along. The experimental flue was fitted with dampers in such a manner that it could be filled with the fumes and closed at both ends, or could be used as a branch or loop in the main flues. The electrical machine had one pole connected to the ground and the other to an arrangement of metallic points placed inside the flue—a stout brass rod encircled by a glass tube to insulate it, being carried through the top of the flue, and held in the position desired for the discharging points. A well insulated copper wire connected this brass rod with the pole of the machine, which being kept warm and dry in a shed gave sparks in all weathers of about 4in. in length. Various modifications of the electrical arrangements were tried; but the experiments disclosed the fact that within certain limits, determined by the size of the electrical machine, the more points of discharge the greater or more rapid the effect produced. The first experiments were made upon the "fume" in a stagnant state, by filling the experimental flue with the gases from the main, and closing the dampers at each end. Viewed through the windows the fume had the appearance of a dense fog, but the moment the electric discharge commenced, a whirling movement was observed round the points, and in a very few seconds the foggy matter collected into flakes which were rapidly deposited on the sides and floor of the chamber and the atmosphere became clear. When the fume was permitted to pass through the temporary flue with the rapid motion due to the pressure of the furnace gases, no change was witnessed as it passed the windows, but at the outlet it was found that the foggy matter had been agglomerated into flakes, which in calm weather fell to the ground immediately on escaping from the flue. In this case the pressure forced the fume on too rapidly to allow of the effects of the electric discharge being witnessed through the windows; but it was, nevertheless, deemed satisfactory, and Mr. Walker determined to adopt the method of attacking the fume by the electrical method on the full working scale. At Bagillt there are nineteen furnaces, and the total length of the existing flues is, as we have mentioned above, rather more than two miles. It is calculated that two Wimshurst machines of the latest pattern, with discs 5ft. in diameter, will be able to supply a sufficient number of sparks when driven by a small steam engine, and we believe they have just been finished by Mr. Cribb, an engineer of Chester, who, under the guidance of Prof. Lodge and Mr. Clark, has the carrying out of the practical details of the electrical arrangement. The results obtained in actual practice will be awaited with interest, for if the electric discharge is so efficient with lead fume, it may be equally potent with other matters of a similar nature; indeed, Mr. Walker intends to try it in other branches of metallurgy—*e.g,,* for the condensation of oxide of zinc in the preparation of the zinc-white pigment and of arsenic in the copper-smelting industry. The working cost of the process is a mere nothing compared to the results obtained; while the electrical plant will probably save the great outlay now necessary in erecting the long lengths of flues and condensing chambers, though the lead recovered in these long flues will more than pay the interest on the capital necessary. Quite apart, however, from the commercial consideration of the question, we have the sanitary aspect, and in that view the discovery of Prof. Lodge and Mr. Clark is of the greatest value. In this country we have made the mistake of fouling the atmosphere, and it will take a long time to undo the mischief; but science is lending its valuable aid, and we may yet live to see the days when the sky over our manufacturing towns will be, at any rate, free from artificial "dust." It is not likely that the owners of boiler furnaces will adopt the electrical method of dealing with coal smoke; but there are many cases of manufacturing industries in which the application of the system will be found both beneficial and economical. The researches carried out by Dr. Lodge and Mr. Clark have covered a wider field than is indicated above; but they must be highly gratified that their labours in pure science have been so soon utilised in practical work. The experiment on which the method of dealing with lead fume is based is one of the simplest, and can be repeated readily by anyone possessing a bell-jar and an electric machine, for it is necessary only to fill the jar with a dense atmosphere, such as that produced by the burning of magnesium wire, and pass a series of sparks through it, to witness the remarkable effect of the discharge, and to appreciate the value of the discovery. In his lecture before the British Association, Prof. Lodge said: "It seems not impossible that some use may be made of this aggregating power of electricity on small bodies, such as smoke particles and mist globules"; and he ventured on the rather remarkable suggestion that it might be worth while trying it on even an Atlantic fog. If we recollect, he proposed to mount a Holtz or Wimshurst machine on the mast of a steamer and discharge the electric sparks through the atmosphere. If the effect were to keep a clear space near the vessel it would be useful; but, as most steamers are pushed on, even in spite of fog, it is not easy to understand of what practical utility the experiment would be, for even if the atmosphere were cleared, the steamers would be continually leaving the cleared portion behind. Still, an application of a discovery of pure science having once been made, there is every possibility that its utilisation will develop, although it is not to be expected that every laboratory experiment will receive so remarkable a recognition as that made by Prof. Lodge and Mr. Clark on the effect of electricity upon dust.

## THE INTERNATIONAL INVENTIONS EXHIBITION.—IX.

### Electricity.

ELECTRICITY is nowadays connected more or less intimately with so many of the arts that, although it has its special group (XIII.) in the East Arcade, it is to be found in one or other of its applications all over the buildings and in the grounds. Illumination by electricity is one of the features of the exhibition, and it must be confessed that in this respect the "Inventions" has the finest installation ever seen; but it also possesses a full-size electric tramcar on Mr. Holroyd Smith's plan in the South Promenade, a large-size model of the Portrush and Giant's Causeway electric tramway exhibited by Mr. W. A. Traill, and a working model of the late Prof. Fleeming Jenkin's "telpher" line—the two latter in the East Avenue and East Gallery, immediately adjoining the East Arcade. Several of the exhibitors in the group have cause to complain of the darkness of the spot allotted to them for their stands; but it is probable the authorities considered that there would be a sufficient number of electric lights to illuminate all the stands. Electric lights, however, cost a good deal of money, and exhibitors do not care to run them throughout the day merely for the benefit of those who, having no light themselves, are unfortunately placed in the darker parts of the Arcade. So far as the Exhibition is concerned, the exhibits in the group are all, without exception, "inventions" since 1862; but so much attention has been devoted to electrical appliances in the technical and even in the newspaper press, that there are comparatively few novelties to be seen. Nevertheless, the visitor has an opportunity of inspecting the actual apparatus and familiarising himself with details of applications of the current which he has already studied in black and white. Entering the East Arcade, he will find an attractive exhibit set out by Messrs. Coxeter and Son, of Grafton-street East, W.C., consisting of a collection of apparatus used in medical electricity, with a curiosity in the shape of an ingenious contrivance for driving a small dynamo by means of water, the speed being regulated by the tap on the supply pipe. Where a current is required for a short time only at intervals this arrangement will probably be found economical and practicable whereever a sufficient pressure of water can be obtained. Electric bells, dynamos, arc lamps, incandescent lamps, portable lamps, switches, lampholders, &c., are shown by several exhibitors; but most of the arrangements are well known, and do not require any special notice. Crompton and Co., of Chelmsford, show on their stand a collection of apparatus, which is of historical importance, indicating the improvements which have taken place within the last five or six years in the manufacture of the Crompton Bürgin machine, the latest form of which has a drum armature with a core of soft iron discs, spaced at intervals to afford free ventilation. A series of arc lamps is instructive, because it shows how, when Necessity calls, Invention answers, and provides increased efficiency with greater simplicity. Mr. S. A. Varley, of Highbury, exhibits machines and appliances which have become historical, and the Anglo-American Brush Electric Light Corporation have a collection to illustrate the construction of the famous Brush machine, including the new armature, which we illustrated on p. 384, Vol. XXXIX. An exhibit which will attract attention is a fine electrical turret clock, by Mr. C. Shepherd, of Alexandra-road, N.W., which strikes the hours and quarters. The armature is somewhat of an ∞-shape, the bent ends entering alternately hollow electromagnets, while the oscillation gives motion to a crank which drives the clock movement. The Electrical Power Storage Co. have a fine exhibit of their secondary batteries, an arrangement of 30 cells being employed to work a number of lamps and a couple of Reckenzaun motors of 1½ and 3 horse-power respectively, the latter being shown attached to a propeller, and of the exact dimensions suitable for a 40ft. launch. Examples of Mr. Sellon's heater applied to the so-called Tobin ventilating tube, to foot warmers, for beds and railway carriages, to an incubating machine, &c., will attract attention. The heater consists of one or more reticulated fireclay slabs, the interstices of which contain coils of iron wire, which offer considerable resistance to the passage of the current. The heat thus generated is absorbed by the fireclay, and air passing through can be heated to 200° Fahr. One horse-power taken from an axle is sufficient to heat nine of the railway foot warmers. A portable accumulator lamp will attract much attention, as it is put up in a neat box for domestic purposes. The lamp gives five candles for six hours, and the accumulator can be charged with five cells of Bunsen or bichromate type. For those who require a portable electric lamp and prefer to carry an accumulator instead of a primary battery, this arrangement is well adapted, and is, we should say, cheap. At the adjoining stand Mr. Sarney, of Ablett-street, South Bermondsey, exhibits his improvements in secondary or storage batteries, which consist in a special form of lead plate and a porous composition, the particulars of which cannot be given until the patent is completed. The lead plate is something in the form of chevaux de frise, the solid rod extending from top to bottom, affording an excellent conductor to all parts of the electrode. The blades or leaves of the chevaux de frise offer an excellent means of retaining the porous composition in place, and when they are pressed as nearly flat as possible, the plate occupies but little space, while exposing a large surface from which the composition cannot fall off. Mr. Sarney's wood cells deserve a word or two of notice. Parts are simply recessed to take the edges of other parts, which, instead of being cut to fit are forcibly compressed, so that when they are swollen by the fluid they form perfectly tight joints, and the cell is retained in shape by a few bolts and nuts. A common ochre paint is found to be a sufficient dressing, and is proof against the acid for a very long time. The School of Electrical Engineering and the Primary Battery Co., Princes-street, Hanover-square, W., exhibit the siphon recorder and other telegraph appliances, with the primary batteries which "work for long periods without recharging," and the waste products of which are allowed for when returned. A. R. Sennett and Co., of Hatton-garden, have a patent primary battery, too, and also exhibit a patent accumulator, and sundry apparatus and fittings. Of other exhibitors much the same may be said, and so far as the public is concerned it is a pity that explanations are not appended to the articles, for the attendants, when any are attached, are not always in the way. We have no doubt that most of the patent batteries have been described in our columns, as has the patent ozokerited core exhibited by W. T. Henley's Telegraph Works Company, at whose stand an interesting object will be found in the magneto-exploder used in 1858 for firing the charges in breaking down the rocks for Portland Breakwater. Specimens of the ozokerited core, according to high testimony, have withstood 14,000 volts without breaking down, and have given an insulation of 40,000 megohms per knot. At the adjoining stand is shown Callender's compound for insulating telegraph and other electrical conductors. For this it is stated that when applied with the troughs containing a tolerably thick mass of the compound, the loss on a current of 2,000 ampères is less than 8 per cent. in 100 yards. The United Telephone Co. have an historical collection of telephones—not the actual instruments, but others made to pattern. Thus the earliest form of Bell's telephone, before any published description had appeared, was of the vertical pattern with the membrane armature; then the famous horizontal pattern known as the ENGLISH MECHANIC telephone, which was exhibited by Sir W. Thomson, in Glasgow, in 1876, and lastly the modern forms finished and in skeleton. Edison's most notable telephones are also exhibited, including a fine specimen of the phonograph—an instrument which has at present failed to find any useful application. The Bernstein Electric Lamp Company exhibit their incandescent lamp, and a neat model of a portion of a city illuminated by incandescent lamps carried on the ordinary posts. Mr. J. H. A. Macdonald, of Edinburgh, exhibits his holophote course indicator in this group. It consists of an electric arc lamp with a reflector, which is so connected to the helm that it indicates by its sweeping movement the side to which the vessel's head is being turned. Prof. G. Forbes exhibits the first model of his non-polar dynamo, which is especially suitable for electroplating, and for refining metals. At 2,000 revolutions it is said to give two volts and 5,000 ampères. The stand of Mr. J. W. Swan is for many reasons the most attractive in the group. It is one of the largest and it is one of the most varied, for incandescent lamps of all sizes are shown applied to different purposes. There is a 100-candle lamp with a reflector attached to a magic-lantern; a portable miner's lamp worked by an accumulator, which gives 2½ candles for four hours; microscope lamps and fairy lamps by the hundred, and a binocular microscope fitted with incandescent lamps in the manner described by Mr. C. H. Stearn, F.R.M.S., in the illustrated paper which we reprinted in No. 933. The surgeon's electric lamp, designed by Mr. J. B. Payne, and made by Mawson and Swan, Newcastle-on-Tyne, is intended for illuminating cavities in the body, and the small lamp is inclosed in a tube which is kept cool by the circulation of water. Mr. Swan also exhibits an ingenious surgeon's lamp devised by Mr. P. Ward, in which the light is sent by reflection down a glass rod, which can thus be introduced to any part without transmitting heat. The utilisation of the incandescent lamp in articles of ornament or decoration has been carried to a high degree of perfection, as can be seen at this stand—the illuminated pearl in the oyster-shell being an interesting example. Samples of the new filament material—cellulose forced through a plate as in wire drawing—are also shown in the thread form and woven into a handkerchief. Laing, Wharton, and Down, of Holborn Viaduct, exhibit the Thomson-Houston system of electric lighting for the first time in England. The system is automatic, and light can be turned on or off without attending to the dynamo. Lamps and other fittings are shown at the stand, with the automatic current regulators, and, as a novelty, some Swan lamps which have been in use at Hatfield House for upwards of four years. On the opposite side of the Arcade, Mr. Crookes has an interesting collection of specimens, including the radiometer and sundry samples of earths and chemicals with which his name is identified. He also shows incandescent lamps in various stages of manufacture, and his cellulose filaments, with a selection of carbon threads, some of them tied in knots after carbonisation to exhibit their flexibility. L. B. Miller, of Hatton-garden, shows in a case some electro-motors and electric meters which deserve attention, but which would require more space than we can afford here to explain; and E. Oppermann, of Spencer-street, E.C., has some improved batteries and a speed governor which will attract notice. A curious exhibit is that of A. J. Kendall, Middlesbrough, which is of more than passing interest, for it is an attempt to provide a means of converting the combustion of fuel directly into electric energy. This is a subject which is engaging the earnest attention of investigators, and though Grove's gas battery is perhaps the nearest approach to a solution of the problem that we have at present, there is reason to think that by-and-by someone will discover a means of using coal directly, instead of passing its potential energy through a steam-engine and a dynamo, and consequently losing a high percentage of the available power. Mr. Kendall's battery is based on the fact that hydrogen passes through a red-hot platinum plate. He uses two platinum tubes, one within the other, and separated by a fluid medium of fused glass. The tubes are closed at one end, and the inner is fed continuously with hydrogen, and kept at a high temperature by means of a gas blowpipe or a furnace. The absorption of hydrogen by the platinum is accompanied by the generation of an electric current, which is led away in the usual manner by wires. Mr. F. Walker, of Spondon-road, Tottenham, exhibits his watt meter, which consists of a drum carrying a ruled sheet of paper and a couple of solenoids, one of which is free to move up and down within the other upon a fixed iron core. When no current is passing a spring keeps the movable solenoid out of the other, and the stylus marks a zero line on the drum; when, on the contrary, a current is passing, the two solenoids act in a compound manner, as it were, and the stylus traces a curve on the drum, which is directly proportional to the energy developed in the circuit, and consequently variations are recorded. The instrument can be used in the laboratory, or as a meter in a working circuit for lighting or power, as the slightest fluctuation is correctly registered in the curve traced on the paper. The Globe Electrical and Engineering Company, Dartmouth-street, S.W., amongst their exhibits show samples of Mr. Killingworth Hedges's fusible safety plugs with mica foil, which we believe are found very efficient. H. and E. J. Dale, of Ludgate-hill, have an interesting collection of apparatus, and they are also agents for Bayley's patent electric clutch motor shown at another stand. This is said to be the most efficient electric motor in the market, and is self-starting at full power. It is exhibited by Bayley and Son, of Poole, and consists of an electromagnet provided with an armature, spring, and contact-breaker. In front is placed another magnet, which, with its axis, is free to revolve, and that has a loose disc armature, which is connected by a rod to the vibrating armature of the fixed magnet. The current passing through both magnets, both attract their armatures, and the pull of the fixed magnet causes the revolving magnet to turn on its axis until the spring breaking circuit the loose disc armature is released, only to be immediately attracted again, so that a continuous rotary movement is imparted to the revolving magnet. Mr. R. Grant, Woolwich, exhibits an electro-motor which is said to give 8,000lb. of momentic force per minute with three quart Bunsens, and General R. Macleod Fraser, of Dorset-square, shows a double-action electro-motor, without dead points; but as it is in a case, we can give no details. Mr. Brailsford's electrical tide-gauge and register is shown at one of the stands, and Mr. Thorpe, of Theobald's-road, W.C., exhibits his semaphore indicator and other specialities, including an arrangement for ringing any number of bells continuously. The Kinetic Engineering Co., Brooke-street, E.C., exhibit the Berthoud-Borel cables, and a Breguet-Gramme pedal dynamo for laboratory use, noticeable for the fittings. Gerard and Co. also show laboratory machines, and those who have occasion to employ a current from a dynamo for a short time should not fail to see these arrangements. W. E. Irish, Sunderland, has a collection of his ingenious appliances, including the telephonograph; and F. M. Rogers, of Finsbury-pavement, exhibits his railway station indicator for use in carriages, showing the "next station," his arc lamp for photographic purposes, and his patent electrical weather vane for indicating within a house the position of a wind vane placed outside. Mr. Strangways shows his loud-speaking, long-distance telephone, complete and in parts (we illustrated this in No. 953); and Mr. F. Aylmer, of Leadenhall-buildings, E.C., shows an interesting collection of Trouvé's inventions, including the electric jewellery and dining and drawing-room ornaments. The portable lamp devised by Trouvé is a neat and handy article, and is said to give five candles for 3½ hours. The mere act of lifting it puts the plates into the battery, and the lamp immediately becomes incandescent. Trouvé's motor, with propeller attached, is shown full size, and the exhibitor hopes to obtain permission to attach it to a boat on the lake. A device which will attract the attention of volunteers is the self-indicating electric target of Mr. J. H. Jack, Edinburgh. The target is in segments which when driven in by the compact of the bullet make contact with brass tongue-pieces connected to a series of electro-magnets. The armatures of these magnets, when actuated by the circuit being closed, operate the index of a dial which is divided in colours to show "bulls," "inners," "outers," &c., and also the exact segment of the target which was struck. Davis and Timmins show a large collection of binding screws, terminals, &c., and coils of arsenical bronze and chromium bronze wire for telegraphic and other purposes. We have endeavoured to give an idea of what is to be seen in the group devoted to electricity; but although it is a comparatively small one, considering the area occupied, we have been unable to do more than mention a few of the large number of minor exhibits which will interest all who are studying the various uses to which the current is now applied.

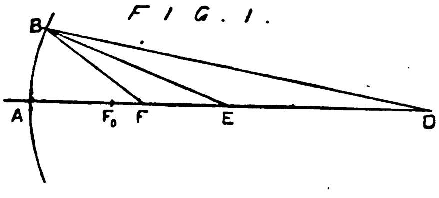
## ON SOME MATTERS IN THE THEORY OF MIRRORS.—I.

By W. BRADBURY.

THERE are a few matters connected with the theory of mirrors, which appear to need further treatment. This is especially the case as regards their aberrational errors, and I take up the subject in the hope of inducing others to carry the analysis further than what I myself am able to do.

In those arrangements of reflecting telescopes in which two curved mirrors are employed, it will always be a difficult and troublesome task to decide when the proportions are at their best. Nevertheless, it is not improbable that theory may yield some useful results, and help the operator to guide his manipulative processes in the right direction.

FIG. 1.



First, we will consider the problem:—

§ 1. To determine the simple focal properties of a spherical mirror.

In Fig. 1, let the curved line, B A C, represent a section through the face of a concave spherical mirror, whose axis is A D, and radius of curvature, A E, or B E. Suppose a ray of light, starting from the point D, and falling on the mirror at B, to be reflected in direction B F, cutting the axis in F. Then F is a focus, and we require to find its position.

From the properties of the triangles, B F E and B D E, and the equality of the angles F B E and E B D, it is easily shown that

$$\frac{FB}{FE} = \frac{DB}{DE} \quad \dots\dots\dots\dots \quad (1)$$

This is a fundamental equation, to which we shall return presently.

If we assume that the mirror has a certain angular aperture, or, in other words, that the angle A E B has a certain value $\theta$; we can, by including this angle in the formula, directly calculate the position of F for any aperture. The equation is:—

$$\frac{1}{FE} = \frac{1}{DE} + \frac{2 \cos.\ \theta}{AE} \quad \dots\dots\dots\dots \quad (2)$$

This formula is one which is very little used, for it will be noticed that the variable distances are measured from the centre E, whereas it is the general practice to reckon them from the vertex A.

In equation (1), it will be seen that two of the chief lines are measured from a point in the curve of the mirror, and will, therefore, alter in length with every change in the position of the point B. As a first approximation, let us suppose that B is so very near to A, that distances measured from either point are practically alike. Then the equation becomes—

$$\frac{AF}{FE} = \frac{AD}{DE}$$

Now $FE = AE - AF$, and $DE = AD - AE$. Making these substitutions and inverting, we have—

$$\frac{AE-AF}{AF} = \frac{AD-AE}{AD} \text{ or } \frac{1}{AF} + \frac{1}{AD} = \frac{2}{AE} \quad \dots \quad (3)$$

This is the common approximate rule for finding the positions of the conjugate foci of a mirror; and is expressed in words by saying that the sum of the reciprocals of the conjugate focal lengths is equal to twice the reciprocal of the radius of curvature.

When the rays are parallel, the reciprocal of A D vanishes, and we have—

$$\frac{1}{AF} = \frac{2}{AE} \quad \dots\dots\dots\dots \quad (4)$$

that is, the focal distance A F is then equal to half the radius of curvature. This is called the principal focal length of the mirror, and is generally represented by F or $f$. For the present we shall represent it by $f$, the radius A E by $r$, and the conjugate focal lengths A D and A F by $u$ and $v$ respectively.

Equation (3) may then take the following form:—

$$\frac{1}{v} = \frac{1}{f} - \frac{1}{u} \quad \dots\dots\dots\dots \quad (5)$$

Referring to Fig. 1, we see that this is the equation for diverging rays on a concave mirror, the point of divergence being without or beyond the centre of curvature. The distances $v$, $f$, and $u$, are measured in the same direction, that is, these points lie on the *same* side of the vertex of the mirror; and we must be careful to notice that equation (5) represents them in this position. The second part of the equation is, of course, the most important, as it governs the sign of the first part; for, in general, $f$ and $u$ are given, and from them $v$ is to be determined.

It is evident from equation (5) that so long as $u$ is greater than $f$, $v$ will be positive; when $u = f$, the reflected rays are parallel; and when $u$ is less than $f$, the reflected rays diverge from the mirror, and their virtual focus, or the position of $v$, is on the opposite side of the mirror. The values of $u$, corresponding to real values of $v$, are limited between the points $F_0$ and E, the former being the principal focal point. It need scarcely be remarked that the course of the rays traced either way is alike—that is to say, if D be a radiant point, the rays from which come to a focus at F, then conversely D is a focus for rays diverging from F.

When the incident rays are converging, the point D is located behind the mirror, so that A D or $u$ is measured in the opposite direction: hence the sign of $u$ in the focal equation must be changed, and it becomes

$$\frac{1}{v} = \frac{1}{f} + \frac{1}{u} \quad \dots\dots\dots\dots \quad (6)$$

which shows that whenever converging rays fall on a concave mirror, there will always be a real focus, situated between the principal focus and the vertex.

This concludes the cases of reflection by a concave mirror.

§2. To find the corresponding formulæ for a convex mirror.

In this case the radius $r$, and, consequently, the principal focal length $f$, are measured in the opposite direction; and when the corresponding change is made in equation (5), it becomes—

$$\frac{1}{v} = -\frac{1}{f} - \frac{1}{u} \quad \dots\dots\dots\dots \quad (7)$$

This shows that whenever diverging rays fall on a convex mirror, the focus is always virtual and behind the mirror at a less distance from it than its principal focus. For, in the above eqn., since both $f$ and $u$ have negative signs, $v$ must always be negative also.

Secondly, for converging rays we must change the sign of $u$ in eqn. (7), and we have—

$$\frac{1}{v} = -\frac{1}{f} + \frac{1}{u} \quad \dots\dots\dots\dots \quad (8)$$

which indicates that we can only have a real focus when $u$ is less than $f$. If $u = f$ then the reflected rays are thrown paralled from the mirror; or if $u$ is greater than $f$, then both incident and reflected rays have virtual foci behind the mirror.

TABLE OF FOCAL EQUATIONS.

CONCAVE MIRROR.

| | | | |
|---|---|---|---|
| 1 | Parallel Rays .. | $f = r \div 2$ | The focus is positive or real |
| 2 | Diverging Rays | $\frac{1}{v} = \frac{1}{f} - \frac{1}{u}$ | $v$ is real when $f < u$<br>$v$ is negative when $f > u$ |
| 3 | Converging Rays | $\frac{1}{v} = \frac{1}{f} + \frac{1}{u}$ | $v$ is real in all cases |

CONVEX MIRROR.

| | | | |
|---|---|---|---|
| 4 | Parallel Rays .. | $-f = r \div 2$ | The focus is negative or virtual |
| 5 | Diverging Rays | $\frac{1}{v} = -\frac{1}{f} - \frac{1}{u}$ | $v$ is virtual in all cases<br>$v$ is virtual when $f < u$ |
| 6 | Converging Rays | $\frac{1}{v} = -\frac{1}{f} + \frac{1}{u}$ | $v$ is real when $f > u$ |

CORRESPONDING POSITIONS OF THE CONJUGATE FOCI:—

Concave Mirror.

$$u \dots\ \frac{f}{2},\ f,\ \tfrac{3}{2}f,\ r,\ 3f,\ \infty,\ -\frac{f}{2}$$

$$v \dots\ \frac{f}{2},\ \infty,\ 3f,\ r,\ \tfrac{3}{2}f,\ f,\ \ \frac{f}{2}$$

Convex Mirror.

$$u \dots\ \frac{f}{2},\ f,\ \infty,\ -r,\ -f,\ -\frac{f}{2},\ -\frac{f}{3}$$

$$v -\ \frac{f}{3},\ -\frac{f}{2},\ -f,\ -r,\ \infty,\ f,\ \frac{f}{2}$$

In the equations of conjugate foci it is usual to employ an auxiliary quantity $a$, determined as follows:—If we suppose—

$$\frac{1}{u} = \frac{1+a}{2f}$$

It follows from equ. (5) that—

$$\frac{1}{v} = \frac{1-a}{2f}$$

since the sum of these two quantities is the reciprocal of $f$. Hence, instead of $u$ and $v$, we may employ the single term $a$, and thus often simplify the calculations. When we are given any value of $u$, that of $a$ may be readily found, since—

$$a = \frac{2f}{u} - 1 \quad \dots\dots\dots\dots \quad (9).$$

Let us find what are the values of $a$, corresponding to the values of $u$ given above.

Concave Mirror.

$$u \dots\ \frac{f}{2},\ f,\ \tfrac{3}{2}f,\ r,\ 3f,\ \infty,\ -\frac{f}{2}$$

$$a \dots\ 3,\ 1,\ \tfrac{1}{3},\ 0,\ -\tfrac{1}{3}\ -1,\ -5$$

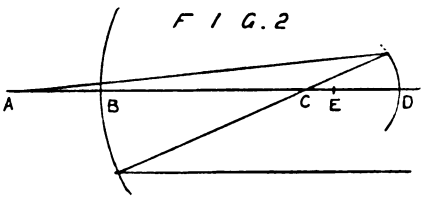
Convex Mirror.

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| $u$.... | $\frac{f}{2}$, | $f$, | $\infty$, | $-r$, | $-f$, | $-\frac{f}{2}$, | $-\frac{f}{3}$ |
| $a$.... | $-5$, | $-3$, | $-1$, | $0$, | $1$, | $3$, | $5$ |

§ 3. To apply the preceding formulæ to the Gregorian telescope.

In this case we have a pair of concave mirrors, so arranged as to bring the final focus at or beyond the vertex of the greater mirror. Let Fig. 2 represent such an arrangement, A

FIG. 2



being the final focus, B the vertex of the large speculum, and C its focal point; D the vertex of the small speculum, and E the place of its principal focus. Let A B = $a$, B C = F, C D = $u$, A D = $v = a + F + u$, D E = $f$. Parallel rays falling on the large speculum are brought to a focus at C; from here they diverge upon the small speculum, are reflected back, and brought to a focus at A, the place of the eye-piece. Hence this case of reflection comes under eqn. (3), bearing in mind what is there said respecting the interchangeability of the focal and radiant points A and C. Since, in this case, C D = $u$, A D = $v = a + F + u$, we have:

$$\frac{1}{u} + \frac{1}{v} = \frac{1}{u} + \frac{1}{a + F + u} = \frac{1}{f} \quad \ldots\ldots\ldots(10)$$

or in a simpler form—

$$u^2 + u(F + a - 2f) = f(F + a)$$

a quadratic equation giving the value of $u$.

The value of F is always known, as is also that of $a$; for the problem is, in fact, to find how far the mirrors must be apart so as to cause the final focus to fall at a certain assigned position. We can, therefore, within certain practical limits, give $a$ any positive value down to zero; and since F and $a$, when once decided on, have a constant value, let us represent them both by one term $m$, that is $(F + a) = m$. Then we have—

$$u^2 + u(m - 2f) = fm.$$

The solution of this equation gives—

$$u = f - \frac{m}{2} \pm \frac{\sqrt{m^2 + 4f^2}}{2} \quad \ldots\ldots\ldots\ldots\ldots(11)$$

But B D, the distance apart of the mirrors, is obviously equal to (F + $u$). Hence, adding F to both sides of the above result and replacing $m$ by (F + $a$).

$$BD = F + f + \tfrac{1}{2}\left\{\sqrt{(F+a)^2 + 4f^2} - (F + a)\right\} \quad ..(12)$$

Also C E, the distance apart of the principal foci of the mirrors is $(u - f)$, or—

$$CE = \tfrac{1}{2}\left\{\sqrt{(F + a)^2 + 4f^2} - (F + a)\right\} \quad \ldots.(13)$$

Hence it appears that the distance apart of the mirrors is always slightly in excess of the sum of their foci. We might, in fact, express the quantity under the vinculum in the form of a series, the second and other terms showing its excess above (F + $a$); which excess is the amount B D exceeds (F + $f$).

As a special case, suppose that the point A coincides with B, so that the value of $a$ is 0; then we have—

$$BD = F + f + \tfrac{1}{2}\left\{\sqrt{F^2 + 4f^2} - F\right\}$$

Also let us assume that the ratio of the foci of the great and small mirrors is $r$, that is $(f \div F) = r$, then—

$$BD = F\left[1 + r + \tfrac{1}{2}\left(\sqrt{1 + 4r^2} - 1\right)\right] \quad \ldots.(14)$$

This is the exact value of B D for the above position of A; but we may find an approximate one in the following manner:—

$$\sqrt{1 + 4r^2} = 1 + 2r^2 - 2r^4 + \&c.$$

Therefore, by introducing these three terms in the above eqn.—

$$BD = F(1 + r + r^2 - r^4) \quad \ldots\ldots\ldots\ldots\ldots(15)$$

This gives the separation in terms of the focal length F and the ratio F/$f$. In ordinary cases the error introduced by using rule (15), instead of (14), is very small. Thus, suppose $r = \frac{1}{3}$,

$$BD \text{ from } (14) = F \times 1{\cdot}4341$$
$$BD \text{ from } (15) = F \times 1{\cdot}4320$$

The error in this case is only about $\frac{1}{300}$ part of F.

It must be observed the eqns. (14) and (15) apply only to the case when the final focus is at the vertex of the large mirror. Under any other circumstance the focal excess C E must be calculated by eqn. (13), and this, added to (F + $f$) is the distance apart of the mirrors.

(*To be continued.*)

## ENGINE-MAKING AT HOME—VII.

### Fitting the Cylinder.

THIS is a nice little bit of fitting, and I should remark that it does not much matter whether we bore or file it first of all; but in practice it is usual to bore first, to ascertain whether the metal is sound, and to use the bore as a basis of measurement when planing the faces and feet. The boring I shall suppose to be done in a lathe, and not in a special boring machine.

With a slide-rest and a lathe, the accuracy of which can be depended upon, a small cylinder such as this is can be bored very well while held in the jaws of the face-plate. The flange affords a very convenient means of attachment, the jaws pinching it upon the outside. Or with a slotted face-plate simply, without jaws, the flange is held by means of two strips of iron plate clipping the flange upon its inner face, themselves being held tightly with bolts passing through the slot holes.

Then the head metal is cut off with a parting tool, and one flange—the outer one—is faced. The cylinder is then bored with a roughing tool first, and finished with a fine cut in the second traverse of the rest. It is afterwards rechucked by the face flange, and the opposite flange turned.

Another way, and one somewhat better than the last, is to remove the upper parts of the slide-rest and to block up and bolt the cylinder to the saddle (Fig. 84), and to bore with a cutter wedged or screwed in a cutter bar (Figs. 85, 86), or with a cutter-head affixed to a mandrel (Figs. 87, 88). Here the cylinder travels while the cutters simply revolve. The stouter the cutter-bar, or the mandrel which carries the cutter-head, the less chatter will there be in the tool. There may be one only, or two cutting edges in the tool wedged in the bar. I have shown two in Fig. 85, and one in Fig. 86. There may be one, Fig. 88, in the boring head, or more, depending upon the diameter and the rate of travel, since the greater the number of cutters the less work each has to do, and the quicker the feed that may be imparted to the head. Three cutters are shown in the head (Fig. 87). The cutters, it will be observed, are ground to an obtuse angle at the front or cutting edges *a*, *a*, *a*, and having no true cutting angle on their faces, they act simply as scraping tools. The sides, *b*, *b*, *b*, which follow the cutting points, merely act as steadies by filling up the bore, and are not intended to cut at all. The cutter head is better than the bar for this reason. It consists simply of a block of cast iron, slotted, to receive the cutters and bored for the mandrel. The cutters are held in place with wedges, having the slightest possible quantity of taper. A cutter and wedge are shown enlarged at Fig. 89. When one cutter only is employed in the head, the remaining grooves are occupied with steady blocks of hard wood.

The head metal must be cut off with a parting tool before the boring commences, the cylinder being held temporarily on the face-plate for that purpose. The bore will be enlarged at each end for about ⅜in. (Fig. 90), the purpose of which is to prevent the formation of a shoulder in the cylinder, as it becomes worn by the friction of the piston.

The flanges can be faced in two or three ways. They might be faced on the plate before the cylinder is removed to the saddle, or they might be faced on the saddle, as is often done by a star wheel and screw arrangement. But as this means making a special apparatus, I should face them by means of a cutter set in the block, and standing far enough out to embrace the diameter of the flange (Fig. 91). By taking light cuts, it would scrape the whole surface of the flange at once, and by making it double-ended, we can face the opposite flange by simply sliding the cutter head along on its mandrel. This will be the best way in this instance; for, being all worked at one setting—we shall be certain that the faces of the flanges will be at exact right angles with the cylinder bore.

Or, again, the cylinder after being bored may be removed from the saddle and bolted to the face-plate, the end against the face-plate being set true concentrically. But the end farthest from the plate may be out of centre by reason of the unevenness of the flange face, so the cylinder is run round, and tried with the point of a scriber to find the amount of eccentricity of the bore at the front end, and the flange next the plate is packed until the front as well as the back of the bore runs truly circular. Then the flange is faced with a cutter fixed in the slide-rest and traversed, and a centre line is marked for the bolt holes to 4⅝in. diameter. A very light cut taken off the diameter of the flange, and an application of emery cloth will improve its appearance. The cylinder is then reversed, the faced flange bolted in turn to the plate, and the second flange faced, and its circle of hole centres marked.

Next try with the square the holding down flange relatively to the steam-chest flange, and if these faces are not at right angles with each other, divide the amount of error between the two when filing. File the holding-down flange first, to its dimensions, and fit its edges into the guides upon the bed. Much depends on the parallelism of these strips with the bore of the cylinder, for any slight inaccuracy here will be multiplied by the length of the piston and connecting rods. The way to insure truthful results is to fit a slip of wood at each end of the cylinder bore, and mark thereon the exact centre of the hole. Then to cut out of thick stuff, 1in. or 1¼in. thick, two semi-circular hollowed pieces of blocking (Fig. 92), and to lay the cylinder upon these foot upwards, shaving down the blocks until the centres marked on each end of the cylinder measure exactly the same height from a level plate when tried with a scribing block (Fig. 90). Having these level, chalk the ends of the cylinder feet, and scribe a line along on both ends at a height of 2$\frac{9}{16}$in. above the centre (Fig. 92). This is the line to which the bottoms of the feet are to be filed. Then, with a set square, raise a line up through the cylinder centre upon the flange faces, and from each side of the centre line so obtained, mark off $\frac{7}{16}$in, equal to one-half the width of the guide strip. At the same time scribe up the ends of the steam-chest flange with the set square to a distance of 3¼in. from the centre (Fig. 92). Centre pop all these lines at intervals of about an ⅛in., and if these are filed accurately to, there should be no need of fudging afterwards. When the steam-chest flange has been filed true, the valve face will follow, being reduced until it stands at exactly an ⅛in. above the flange face, such thickness being gauged by a slip of metal slid underneath a straightedge, whose face is held against the valve face. Measurement may also be taken at the same time to the cylinder bore. The bounding edges of the valve face will be filed also to 3¾in. by 2$\frac{3}{16}$in., the longitudinal edges being checked first from the cylinder foot, and the transverse edges with a square laid against those first named, or with a scribing block.

Returning the cylinder to its blocks, get the centres levelled once more by the scriber point set against the horizontal line marked on the temporary slips of wood driven into the cylinder ends. Erect a centre line upon the slide-valve face, which should be the centre alike of the exhaust port and the faces of the cover flanges. From this centre mark the width of the exhaust = ⅜in. to right and left of the centre line, then $\frac{5}{16}$in. = the width of the bars, then ⅜in. = the width of ports, and scribe up lines to these divisions. Chip lightly if the metal will allow of chipping, or file if the cores are nearly to the finished size, having much regard to the exactitude of the outside port edges. Afterwards file the pump facings square with the cylinder foot to a distance of 2¾in. from the centre, and also the flange of the exhaust-pipe square with the valve face. Then at this stage the cylinder will be put aside for a few hours while the covers are being prepared.

The covers will be turned to the sectional dimensions (Figs. 93, 94). The outside faces and the edges may as well be polished as is customary, for appearance sake. Of course, there are different ways of chucking, but I should proceed thus, taking the bottom cover first:—Clip the edge of the cover in the jaws of the face-plate, letting the inner face of the cover stand outwards, and turn that face first. Then clip the shouldered portion with the dogs, or drive it into

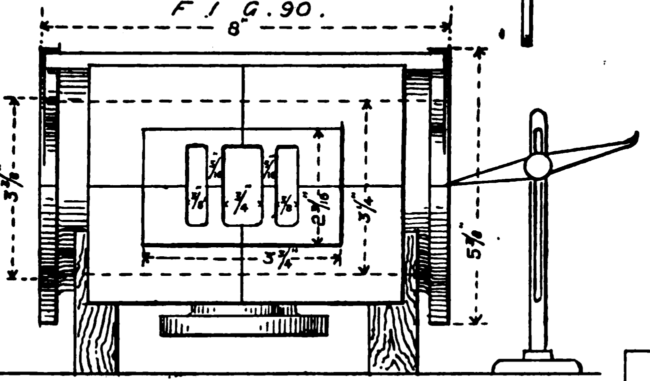

FIG. 90.

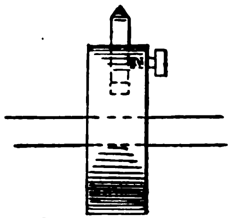

FIG. 92.

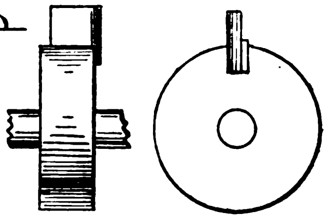

FIG. 91.

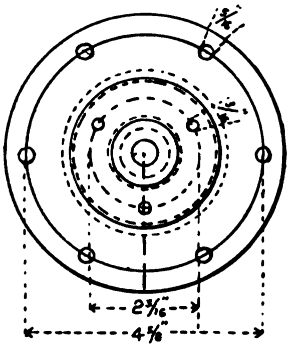

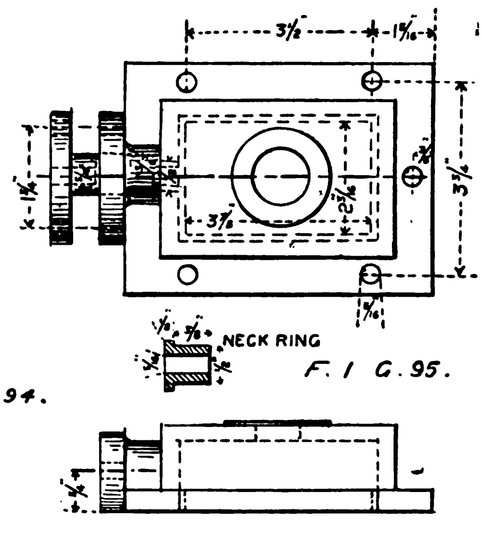

FIG. 95.

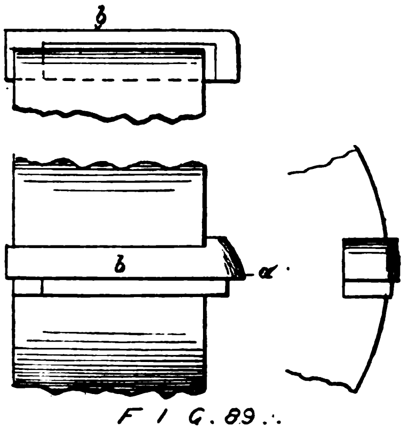

FIG. 89.

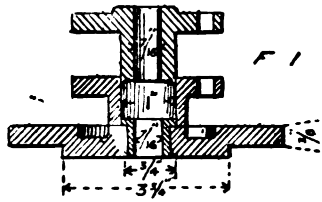

FIG. 94.

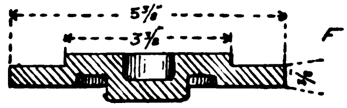

FIG. 93.

a recess in a hardwood chuck, and skim over and polish the edge and the outside face. The second cover, Fig. 94, will be turned similarly so far as the polishing of the face and edge. But at that stage the clips should be applied to the turned edge for the more secure grip while the stuffing-box is turned and bored. The stuffing-box will be bored with an ordinary turning tool to 1in. diameter, and the blank metal at the bottom will be drilled in the lathe to ⅝in. diameter. Run a line round for the bolt centres on the flanges to 4⅝in. diameter, and another on the flange of the stuffing-box to 2 3/16in. diameter, and remove from the lathe. From a bit of solid brass rod turn a neck ring to the dimensions (Fig. 94), and drive it tightly into the drilled hole at the bottom of the stuffing-box. Mark out the centres of six holes equidistantly from one another upon the 4⅝in. diameters struck on the flanges, and on each of these centres strike a 3/16in. circle. Centre-pop these circles and drill. Mark three 3/16in. holes upon the stuffing-box flange and drill. Drop the covers into their respective ends, and starting in each case with two of the holes exactly plumb (Fig. 92), use the holes already drilled in the covers as the templet or guide for marking those which have to be drilled in the flanges. Centre-pop, and drill those marked *a*, *a*, *a*, to 3/16in. for the reception of bolts, *b*, *b*, *b* being drilled to ⅛in. only, to be tapped for the reception of studs — the employment of studs being necessary because the presence of metal behind the flanges in these points prevents the employment of nuts.

Turn and bore the gland (Fig. 94), to the dimensions there given, its flange being clipped by the dogs while the hole is being bored, the body turned, and the under shoulder faced. With a twist drill in good order, held in the slide-rest, the hole for the piston can be drilled through directly without any need of boring proper. It must be rechucked, and the body clipped in order to turn the top face and edge of the flange. Three ⅛in. holes will be drilled to correspond with those in the flange of the stuffing-box for the gland bolts.

The steam-chest, Fig. 95, may receive our next attention. File the face of its flange, and also the four strips around its inner edges, taking most pains with the facings against which the edges of the slide-valve travel. Chalk the face of the stuffing-box, and measuring equidistantly from the edges of the guide strips against which the edges of the slide-valve travel, draw a centre line along the face of the flanges and up the stuffing-box face. Intersect this last with another centre line scribed horizontally at a distance of ⅝in. from the flange face. Then bolt an angle plate to the face-plate of the lathe, and laying the surface of the flange just now filed against the angle plate, adjust the latter in one direction, or radially, and the former in the traverse direction, until the intersection of the centres upon the stuffing-box coincides with the lathe centre. Drill to the dimensions, Fig. 95, turn a neck ring of brass, as figured, and the gland also, as in the case of the cylinder cover. Two 3/16 holes will be drilled in the flange of the stuffing-box, and tapped to ¼in., and two ¼in. holes in the gland to slip over the studs. Five 3/16in. holes drilled in the flange for attachment to the cylinder will complete the work on the steam-chest for the present.

---

**CHIMNEY** area is calculated by allowing 3¼ square feet for every full-sized boiler—i.e., 28ft. by 7ft., and 4 square feet for one boiler.

## SIMPLE EXERCISES IN TECHNICAL ANALYSIS.—VIII.

By An Analytical Chemist.

### Section II.—Pigments.

THE subject of paints having been now dealt with at sufficient length to meet the requirements of all who are interested in the examination of the quality and the adulteration of these substances, our attention must now be directed to the methods employed for estimating the value of the pigments used in painting. In the colour trade small dealers seldom subject pigments to any but a rough-and-ready mechanical test, and frequently to no test at all. They buy them relying on the respectability of the wholesale dealer, and, without inquiring further into their value, pass them on to the consumer. But dealers who buy in large quantities, and who are anxious to establish or maintain a good reputation, are always careful to submit their pigments to examination, and by so doing not only add largely to their fame but to their profits as well. The opinion of experienced chemists can be obtained for a mere trifle compared with the loss which might be sustained by the purchase of one expensive pigment which turned out to be of inferior quality; and all large purchases are now consequently bought subject to analytical examination. The real value of most pigments—especially the expensive ones—can only be ascertained by experienced chemists and by careful chemical examination.

The number of pigments is very great, but we shall confine ourselves to those commonly used in ordinary painting.

### White Pigments.

(110.) The most important of the white pigments in use at the present time are White Lead and Zinc White. The former surpasses all other pigments in covering power, but is open to the objection that it blackens in atmospheres containing sulphuretted hydrogen gas. Zinc white is free from this objection, but it is deficient in covering power. Zinc sulphide, and a mixture of zinc oxide and sulphide, or oxysulphide of zinc, as well as oxide of zinc, are all sold under the name of Zinc White.

Chalk, Sulphate of Lime, Sulphate of Baryta, and Sulphate of Lead are white pigments seldom used alone, but chiefly as adulterants of White Lead and Zinc White. Of white pigments not in common use may be mentioned the following lead salts: The Basic Chloride, Tungstate, Antimonite, Antimoniate, and Antimony Whites. A qualitative examination is all that is necessary for chalk, sulphate of lime, &c.

### White Lead.

(111.) *Adulterants:—*

1. Insoluble silicates.
2. Sulphate of baryta.
3. Sulphate of lead.
4. Chalk.

(112.) *Composition:—*

Dry white lead should contain nothing but lead carbonate or hydrate, and should be of a pure white colour.

Mixed white lead should contain about 90 per cent. of white lead, calculated in the manner described in Art. 7, and 10 per cent. oil.

For method of analysis see Arts. 1 to 11.

### Zinc White.

(113.) The examination of zinc white has been described in Arts. 12 to 21.

(113*a*.) *Adulterants:—*

1. White lead.
2. Sulphate of baryta.
3. Chalk.
4. Insoluble silicates.
5. Magnesia (occasionally).

Pure samples of zinc white consist wholly of zinc oxide, zinc sulphide, or a mixture of both (zincic-oxy-sulphide).

### Yellow Pigments.

(114.) The most important yellow pigments are:—

1. **Chrome yellows and other chromates.**
2. **Ochres.**
3. **Italian and Sienna Earths.**
4. **Vienna red, Antwerp red, Terra Rosa.**
5. **Mars yellows.**
6. **Lakes.**
7. **Orpiment.**
8. **Massicot.**

**Other yellows are:—**

9. **Cassel yellow (oxide and chloride of lead).**
10. **Naples yellow (antimoniate of lead).**
11. **Ultramarine yellow (chromate of baryta).**

### Chrome Yellows.

(115.) For method of testing see Art 38, et seq. The examination of chrome yellows is most important, owing to the variation in the price of the various qualities. Their value depends solely on the per centage of chromate of lead present. The following instructive table shows the results of the analysis of special samples:—

Chrome Yellows.

(Quality as stated.)

| | 1st | 1st | 2nd | 2nd | 3rd | 3rd |
|---|---|---|---|---|---|---|
| Sulphate of Lime | — | — | 70·6 | 13·21 | 88·3 | 25·86 |
| Chromate of Lead | 100 | 53·03 | 29·4 | 82·43 | 11·7 | 66·98 |
| Moisture ........ | — | 1·42 | — | 4·36 | — | 7·16 |
| White Lead .... | — | 19·10 | — | — | — | — |
| Chalk .......... | — | 26·45 | — | — | — | — |
| | 100 | 100 | 100 | 100 | 100 | 100 |

The following table shows the composition of samples of which the quality was not stated:—

Chrome Yellows.

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Sulphate of lime .... | 25 | — | — | 30·6 | — | tr. | 54·4 | — |
| Chromate of lead .... | 75 | 65 | 97 | 69·4 | 70 | 21 | 45·6 | 94·08 |
| Sulphate of baryta ... | — | — | 3 | — | — | — | — | — |
| White lead and chalk | — | 35 | — | — | 30 | — | — | 5·92 |
| Chromate of potash ... | — | — | — | — | — | 79 | — | — |
| | 100 | 100 | 100 | 100 | 100 | 100 | 100 | 100 |

From the above it is evident that nothing short of chemical examination can determine the real value of chrome yellows. And as the price varies from 28s. to 108s. per cwt., it is also evident that an enormous loss might be sustained by purchasing unknowingly a sample of inferior quality. It is indeed a difficult matter to obtain a sample of pure chrome yellow at the colour shop. The writer of these articles could relate many sad experiences in connection with chrome-yellows. One colourman frankly informed him that he never knew what a chrome-yellow was; another guaranteed that his was pure, but was "only cast on barytes." For very good reasons these four words are indelibly engraved in the writer's memory. First quality chrome-yellow should be pure; second quality should contain about 80 per cent.; and third quality 60 per cent., of chromate of lead. Those containing less should be sold as special mixtures, and not as chrome-yellows.

### Lemon Chrome.

(116.) *Composition:—*

| | | | |
|---|---|---|---|
| **Chromate of lead ....** | 51·5 | 43·14 | 68·32 |
| **Sulphate of lead ....** | 47·0 | 54·86 | — |
| **Chalk, water ........** | 1·5 | 2·00 | 31·68 |
| | 100 | 100 | 100 |

(117.) Adulterants the same as for chrome yellows, viz.:

**Sulphate of lime.**
**Sulphate of baryta.**
**White lead.**
**Chalk.**

### Other Chromates.

(118.) Chief among these is the basic chromate of lead. The hues vary from a reddish-yellow to a vermilion red.

When pure—which is seldom the case—they consist of oxide of chromium, with a greater or less excess of oxide of lead. The various tints now usually sold are prepared by mixing the various chromates with other colours.

### Yellow Ochres.

(119.) *Composition:—*

| Water: | | | | | | |
|---|---|---|---|---|---|---|
| Hygroscopic | 4·60 | 3·2 | 7·53 | 9·84 | 10·64 | 5·7 |
| Combined .. | 4·06 | 4·8 | | | | |
| Insoluble silicates, &c. .. | 74·86 | 73·5 | 71·13 | 71·85 | 75·46 | 71·0 |
| Oxide of Iron. | 14·96 | 18·5 | 20·40 | 15·80 | 13·90 | 20·6 |
| Chalk ........ | 1·52 | — | ·94 | 2·61 | — | 2·7 |
| | 100 | 100 | 100 | 100 | 100 | 100 |

For method of analysis see Arts. 29 to 36.

### Italian and Sienna Earths.

(120.) Treat same as ochres.

### Vienna Red, &c.

(121.) See Art. 51.

### Mars Yellow.

(122.) This pigment is of variable composition. It contains oxide and carbonate of iron, and alumina.

### Lakes.

(123.) These are seldom used except for very delicate tints. There are mineral lakes and vegetable lakes. The latter are mixtures of alumina, with colouring matters derived from the vegetable kingdom.

### Orpiment.

(124.) This beautiful pigment is chemically distinguished by the name of arsenious sulphide ($As_2S_3$).

(125.) The usual impurities are:—

1. Arsenious acid.
2. Sand, clay, &c.
3. Chalk or lime.
4. Free S

(126.) Tests for:—

1. *Arsenious Acid.*—Boil the sample in dilute hydrochloric acid, add a little $SH_2$ water. A yellow precipitate indicates arsenious acid.

2 and 3 are insoluble in caustic soda. Test further, as in examples already described.

4. Free sulphur is detected by treating a little of the sample with sulphide of carbon, decanting the liquid, and evaporating to dryness. A yellow residue burning with a blue flame and a suffocating smell is sulphur.

(127.) The samples in the market are usually of good quality. Recently a sample was examined which contained 7 per cent. of lime—an excessive and unusual amount of adulteration in a sample of King's yellow.

### Massicot or Litharge.

(128.) This is oxide of lead. It should be perfectly soluble in nitric acid without effervescence.

(129.) *Adulterants:—*

Chalk.
Earthy substances.

(130.) The latter are usually insoluble in nitric acid, or if soluble may be detected after the lead is precipitated by $SH_2$, as in Art 11.

(131.) The presence of chalk is indicated by effervescence on adding an acid to the sample, by precipitating the chalk, together with the lead, by means of sulphuric acid, washing the precipitate, boiling it in a concentrated solution of ammoniac acetate, filtering, adding to the filtrate oxalate of ammonia, a white precipitate giving a brick-red flame at the blowpipe, the presence of chalk may be confirmed.

### Naples Yellow.

(132.) See Art. 47.

### Ultramarine Yellow.

(133.) This is chromate of baryta—a beautiful lemon yellow pigment. It is completely soluble in hydrochloric acid. The chromium may be estimated as in Art. 34, treating it exactly similar to the precipitate mentioned in that article; and the barium may be estimated by adding dilute sulphuric acid to the filtrate, filtering, drying, and weighing the precipitated sulphate of baryta. Having estimated these, it should be seen that they exist in the proper proportion to form normal chromate of barium. If not, further investigation is necessary; chalk, sulphate of baryta, and sulphate of lime are occasionally present.

The other yellow pigments are rarely met with.

## THE VACUUM CONTINUOUS AUTOMATIC BRAKE.*

UNDER the title above given the Vacuum Brake Company have recently issued a descriptive pamphlet of the mechanism of the continuous automatic brake, with large-sized coloured diagrams which enable the reader to comprehend and thoroughly understand the arrangement and working of the brake. The automatic vacuum brake is applied by the driver or the guard, and is self-acting in case of accidental parting of the train or of damage to the brake itself. It is worked by a combination ejector placed on the engine, and controlled by one handle. This ejector exhausts air from the main pipe running through the train, and so produces a vacuum of about 20in. to 24in. on the top sides of the pistons in the brake-cylinders. When the handle of the ejector is moved to "brake on" air flows to the lower sides of the pistons, which are driven in upon the vacuum, and levers being connected, the brake-blocks are applied to the wheels. The pistons are kept air-tight to their cylinders by means of rolling rings, and there is consequently little friction and loss of power. The diagrams show in full size the ball-valve, the only acting portion of which is the rolling ball; the combination-ejector in one-third size; the guard's valve, the drip-trap, and the universal hose-coupling half size; while the brake-cylinders are shown on the scale of 3in. to the foot. The general arrangements of the brake, as applied to engines and coaches, are drawn on a scale of ½in. to the foot, so that those who desire to understand the mechanism of the Automatic Vacuum-brake will have no difficulty in comprehending its action. In the present practically perfected vacuum arrangement the brake can be applied any number of times without exhausting its power, and as the power is atmospheric pressure, joints are easily kept tight, there being an entire immunity from any tendency to burst the connecting hose, the coupling of which is an ingenious yet simple arrangement which cannot possibly be put together except in the proper manner. The brake is stated to meet all the requirements of the Board of Trade, and as a small ejector is capable of maintaining the vacuum, there is economy in the use of steam.

---

* The Vacuum Continuous Automatic Brake, with Universal Coupling. London: The Vacuum Brake Co., Limited.

## COMMERCIAL ORGANIC ANALYSIS.*

WHEN the first edition of this book appeared some years ago, we expressed, in almost unqualified terms, our appreciation of its usefulness and the care and ability with which it had been written. In reviewing the second edition we are glad to be able to indorse every word we then wrote, and in addition to congratulate the author on the alterations he has had the courage to make in the arrangement of the subject matter, so that each volume should treat more especially of kindred products. Thus, the volume now under notice is devoted chiefly to the consideration of bodies of the fatty series and of vegetable origin; while the second volume, the publication of which is promised shortly, will contain information on oils, hydrocarbons, coal-tar products, and colouring matters. A third volume the author promises to devote to the consideration of nitrogenised organic substances, including cyanogen compounds, alkaloids, and organic bases, albuminoids, &c. We have no doubt this rearrangement of the subject matter will be of great advantage to the reader, by rendering the book more convenient for reference, while adapting each particular volume to the special requirements of certain users.

The volume now issued is divided into six main sections or chapters. The "Introduction" deals mainly with the methods of determining specific gravity, melting and boiling points, specific rotatory power, elementary [composition, &c., of organic substances. Very useful tables are given showing the behaviour of various organic bodies with solvents, and concise directions for searchings for poisonous metals present as impurities in organic matters.

In the chapter on "Alcohols" the various methods of alcoholometry are described, and extended tables of densities of diluted alcohol are given. The articles on wine and beer make their first appearance in this edition, and contain several items of information not generally to be met with. The sections on spirits, liqueurs, and tinctures have undergone little alteration.

Under "Neutral Alcoholic Derivatives," Mr. Allen describes the methods of examining aldehyde, chloral, chloroform, ether, and the various compound ethers employed in medicine and the arts. The section on spirit of nitrous ether probably contains the fullest account of that preparation hitherto published.

The "Sugars" meet with very thorough description. The chapter has been transferred from the second volume of the first edition, and has evidently undergone careful revision. The section on commercial glucose is especially complete, and contains suggestions which we may expect to see utilised for the assay of similar materials. The author describes the inversion of cane sugar by "invertin"—the soluble ferment of yeast, and shows how it may be applied in analysis. An ingenious method of determining cellulose in a complex mixture of sugars is also given. Gallisin and saccharin are fully described, and a remarkably complete account is given of maltose, and the methods of assaying malt products. Here the practical advantage of including the sugars in the same volume as the alcohols becomes fully evident.

Under "Starch and its Isomers," Mr. Allen describes the microscopic examination of starches, the proximate analysis of plants, the detection of adulterants in flour and bread, the analysis of wood tissues, and the assay of gun-cotton, dextrine, gum arabic, and other bodies. Though affording less scope for original treatment than other portions of the book, the chapter contains a mass of information, and is enriched with various tables and a steel engraving showing the microscopic appearance of the adulterants of arrowroot.

The last chapter of the book treats of the "Acid Derivatives of Alcohols and Vegetable Acids." Broadly speaking, it is little changed from the first edition; but in the details of arrangement and in the methods described there are numerous changes. A copious index completes the volume.

In compiling his unique work Mr. Allen has collected items of information from a great variety of sources, and, as he states in the preface, has received the assistance of a considerable number of chemists of special experience in particular directions. This fact adds materially to the value of the book which will certainly maintain the position as a standard work which was attained by the former edition. In a book of so technical a nature, and containing such a multiplicity of formulæ and figures, mistakes are certain to occur, though we are bound to say that a careful inspection has revealed very few of them; but the accuracy and attention to detail shown by the author are the best guarantees that errors and misstatements of all kinds are reduced to a minimum. Thanks to Mr. Allen, the professional chemists, manufacturers, and pharmacists now have a book to which they can refer with confidence, and a certainty of finding everything of value known respecting the composition and assay of organic products.

* Commercial Organic Analysis. By ALFRED H. ALLEN, F.I.C., F.C.S., Public Analyst for the Borough of Sheffield, &c. Second Edition, Volume I. London: J. and A. Churchill.

## THE ELEMENTARY PRINCIPLES OF THE GAS ENGINE.*

BEFORE the invention of the steam-engine, the only powers employed in mechanics were those of wind and water mills and animal power. In the first two no conversion of one force into another took place; they were mere kinematic devices for employing the mechanical force already existing in the gale of wind and the head of water. With regard to the power developed by man and other animals, we had in them examples of most efficient heat-engines, converting into power a large percentage of the fuel burnt in the lungs. But animal power is small in amount, and it is expensive for two reasons—first, because the agents require long intervals of rest, during which they still burn fuel; the next, because the fuel they require is very expensive. A pound of bread, or beef, or oats or beans, costs a great deal more than a pound of coal; while it does not, by its combustion, generate nearly so much heat. The steam-engine, therefore, took the place of animal power, and for a long time stood alone; and nearly all the motive power derived from heat is still produced by the mechanism which Watt brought to such great efficiency in so short a time. Now the practical question for all designers and employers of heat-engines is to determine how the greatest quantity of motive force can be developed from the heat evolved from a given kind of fuel; and coal being the cheapest of all, we will see what are the results obtainable from it by the steam-engine. In this we have three efficiencies to consider—those of the furnace, the boiler, and the cylinder. First, with respect to the furnace, the object is to combine the carbon and the hydrogen of the coal with a sufficient quantity of the oxygen of the air to effect complete combustion into carbonic acid and water. In order to do this, we have to use a quantity of air much larger than is theoretically necessary, and also to heat an amount of inert nitrogen five times greater than the necessary oxygen; and we are therefore obliged to create a draught which carries away to the chimney a considerable portion of the heat developed. The combustion, moreover, is never perfect, and some heat is lost by conduction and radiation. The principal loss is by hot gases escaping from the flues to the chimney. Even with well-set boilers, the temperature in the chimney varies from 400° to 600°. Taking the mean of 500°, this would represent a large proportion of the total heat, even if the combustion were perfect; for, as a general rule, the supply of air to a furnace is double that which is theoretically necessary. For our present purpose it will be sufficient to see how much the whole loss is, without dividing it under the several heads of "imperfect combustion," "radiation," and "convection," by the heated gases passing to the chimney.

With a very good boiler and furnace, each pound of coal evaporates 10lb. of water from 62°, changing it into steam of 65lb. pressure at a temperature of 312°, or 250° above that of the water from which it is generated. Besides these 250°, each pound of steam contains 894 units of latent heat, or 1,144 units in all. A very good condensing engine will work with 2·2lb. of coal and 22lb. of steam per horse per hour. Now, 1lb. of good coal will, by its combustion, produce 14,000 heat-units, and the 2·2lb. of coal multiplied by 14,000 represent 30,800 heat-units. Of these we find in the boiler 22 × 1,144, or 25,168 units, or about 81½ per cent. of the whole heat of combustion; so that the difference (5,632 units, or 18½ per cent.) has been lost by imperfect combustion, radiation, or convection. The water required for condensing this quantity of steam is 550lb.; and taking the temperature in the hot well as 102°, 550lb. have been raised 40° from 62°. Thus we account for 550 × 40 = 22,000, or (say) 71½ per cent. still remaining as heat. If we add this 71½ per cent. to 18½, we have 90 per cent., and there remain only 10 per cent. of the heat that can possibly have been converted into power. But some of this has been lost by radiation from steam pipes, cylinder, &c. Allowing but 1 per cent. for this, we have only 9 per cent. as the efficiency of a really good condensing engine. This estimate agrees very closely with the actual result; for the 2·2lb. of coal would develop 30,800 heat-units; and this multiplied by Joule's equivalent amounts to nearly 24 millions of foot-pounds. As 1 horse-power is a little less than 2 million foot-pounds per hour, only one-twelfth, or a little more than 8 per cent., of the total heat is converted; so that whether we look at the total quantity of heat which we show unconverted, or the total heat converted, we find that each supplements and corroborates the other. If we take the efficiency of the engine alone, without considering the loss caused by the boiler, we find that the 25,168 heat-units which entered the boiler should have given 19,429,696 ft.-lb.; so that the 2 millions given by the engine represent about 10 per cent. of the heat which has left the boiler. The foregoing figures refer to large stationary or marine engines, with first-rate boilers. When, however, we come to high-pressure engines of the best type, the consumption of coal is twice as much; and for those of any ordinary type it is usual to calculate 1 cubic foot, or 62½lb., of water evaporated per horse-power. This would reduce the efficiency to about 6 per cent. for the best and 3 per cent. for ordinary non-condensing engines; and if to this we add the inefficiency of some boilers, it is certain that many small engines do not convert into power more than 2 per cent. of the potential energy contained in the coal.

Before explaining the principle upon which the gas-engine and every other hot-air engine depends, I shall remind you of a few data with which most of you are already familiar. The volume of every gas increases with the temperature; and this increase was the basis of the air thermometer—the first ever used. It is to be regretted that it was not the foundation of all others, for it is based on a physical principle universally applicable. Although the volume increases with the temperature, it does not increase in proportion to the degrees of any ordinary scale, but much more slowly. Now, if to each of the terms of an arithmetical series we add the same number, the new series so formed increases or decreases more slowly than the original; and it was discovered that by adding 461 to the degrees of Fahrenheit's scale, the new scale so formed represented exactly the increment of volume caused by increase of temperature. This scale, proposed by Sir W. Thomson in 1848, is called the "scale of absolute temperature"; its zero, called the "absolute zero," is 461° below the zero of Fahrenheit, or 493° below the freezing point of water; and the degree of heat measured by it is termed the "absolute temperature." It is often convenient to refer to 39° Fahr. (which happens to be the point at which water attains its maximum density), as this is the same as 500° absolute, for, counting from this datum level, a volume of air expands exactly 1 per cent. for 5°, and would be doubled at 1000° absolute, or 539° Fahr.

Whenever any body is compressed, its specific heat is diminished, and the surplus portion is, as it were, pushed out of the body, appearing as sensible heat; and whenever any body is expanded its specific heat is increased, and the additional quantity of heat requisite is, as it were, sucked in from surrounding bodies, so producing cold. This action may be compared to that of a wet sponge from which, when compressed, a portion of the water is forced out, and when the sponge is allowed to expand the water is drawn back. This effect is manifested by the increase of temperature in air-compressing machines, and the cold produced by allowing or forcing air to expand in air-cooling machines. At 39° Fahr. 1lb. of air measures 12½ cubic feet. Let us suppose that 1lb. of air at 39° Fahr. = 500° absolute, is contained in a non-conducting cylinder of 1ft. area and 12½ft. deep under a counterpoised piston. The pressure of the atmosphere on the piston = 144 square inches × 14·7lb., or 2,116lb. If the air be now heated up to 539° Fahr. = 1000° absolute, and at the same time the piston is not allowed to move, the pressure is doubled; and when the piston is released it would rise 12½ft. provided that the temperature remained constant, and the indicator would describe a hyperbolic curve called an "isothermal," because the temperature would have remained equal throughout. But, in fact, the temperature is lowered, because expansion has taken place, and the indicator curve which would then be described is called an "adiabatic curve," which is more inclined to the horizontal lines when the volumes are represented by horizontal and the pressures by vertical co-ordinates. In this case it is supposed that there is no conduction or transmission (diabasis) of heat through the sides of the containing vessel. If, however, an *additional* quantity of heat be communicated to the air, so as to maintain the temperature at 1000° absolute, the piston will rise until it is 12½ft. above its original position, and the indicator will describe an isothermal curve. Now mark the difference. When the piston was fixed, only a heating effect resulted; but when the piston moved up 12½ft., not only a heating, but a mechanical—in fact, a thermo-dynamo—effect was produced, for the weight of the atmosphere (2,116lb.) was lifted 12½ft. = 26,450 foot-pounds.

---

* The substance of a paper by Mr. DENNY LANE, Cork, read before the Gas Institute.

The specific heat of air at constant pressure has been proved by the experiments of Regnault to be 0·2378, or something less than one-fourth of that of water—a result arrived at by Rankine from totally different data. In the case we have taken there have been expended 500 × 0·2378, or (say) 118·9 heat-units to produce 26,450 foot-pounds. Each unit has, therefore, produced $\frac{26{,}450}{118{\cdot}9} = 222{\cdot}5$ foot-pounds, instead of 772 foot-pounds, which would have been rendered if every unit had been converted into power. We therefore conclude that $\frac{222{\cdot}5}{772} = 29$ per cent. of the total heat has been converted. The residue, or 71 per cent., remains unchanged as heat, and may be partly saved by a regenerator, or applied to other purposes for which a moderate heat is required.

The quantity of heat necessary to raise the heat of air at a constant volume is only 71 per cent. of that required to raise to the same temperature the same weight of air under constant pressure. This is exactly the result which Laplace arrived at from observations on the velocity of sound, and may be stated thus:—

| | Specific Heat. | | Foot Pounds. | Per Cent. |
|---|---|---|---|---|
| $K_p$ = 1lb. of air at constant pressure.. | 0·2378 | × 772 = | 183·5 = | 100 |
| $K_v$ = 1lb. of air at constant volume.. | 0·1688 | × 772 = | 130·3 = | 71 |
| Difference being heat converted into power.... | 0·0690 | × 772 = | 53·2 = | 29 |

Or, in a hot-air engine without regeneration, the maximum effect of 1lb. of air heated 1° Fahr. would be 53·2 f.p. The quantity of heat $K_v$ necessary to heat air under constant volume is to $K_p$, or that necessary to heat it under constant pressure, as 71 : 100, or as 1 : 1·408, or very nearly as 1 : $\sqrt{2}$—a result which was arrived at by Masson from theoretical considerations. The 71 per cent. escaping as heat may be utilised in place of other fuel, and with the first hot-air engine I ever saw it was employed for drying blocks of wood. In the same way, the unconverted heat of the exhaust steam from a high-pressure engine, or the heated gases and water passing away from a gas-engine, may be employed.

When I first wrote on this subject I relied upon some data which led me to suppose that the heating power of ordinary coal gas was higher than it really is. At our last meeting, Mr. Hartley proved, by experiments with his calorimeter, that gas of 16 or 17 candles gave only about 630 units of heat per cubic foot. Now, if all this heat could be converted into power, it would yield 630 × 772, or 486,360 f.p., and it would require only $\left(\frac{1{,}980{,}000}{486{,}360}\right) = 4{\cdot}07$ cubic feet to produce 1 indicated horse-power. Some recent tests have shown that, with gas of similar heating power, 18 cubic feet have given 1 indicated horse-power, and therefore $\frac{4{\cdot}07}{18} = 22{\cdot}6$ of the whole heat has been converted—a truly wonderful proportion when compared with steam-engines of a similar power, showing only an efficiency of 2 to 4 per cent.

The first gas-engine which came into practical use was Lenoir's, invented about 1866, in which the mixture of gas and air drawn in for part of the stroke at atmospheric pressure was inflamed by the spark from an induction coil. This required a couple of cells of a strong Bunsen battery, was apt to miss fire, and used about 90 cubic feet per horse-power. This was succeeded by Hugon's engine, in which the ignition was caused by a small gas-flame, and the consumption was reduced to 80 cubic feet. In 1864 Otto's atmospheric engine was invented, in which a heavily-loaded piston was forced upwards by an explosion of gas and air drawn in at atmospheric pressure. In its upward stroke the piston was free to move; but in its downward stroke it was connected with a ratchet, and the partial vacuum formed after the explosion beneath the piston, together with its own weight in falling, operated through a rack, and caused rotation of the fly-wheel. This engine (which, in an improved form, uses only 20 cubic feet of gas) is still largely employed, some 1,600 having been constructed. The great objection to it was the noise it produced, and the wear and tear of the ratchet and rack arrangements. In 1876 the Otto-Crossley silent engine was introduced. As you are aware, it is a single-acting engine, in which the gas and air are drawn in by the first outward and compressed by the first inward stroke. The compressed mixture is then ignited, and, being expanded by heat, drives the piston outwards by the second outward stroke. Near the end of this stroke the exhaust-valve is opened, the products of combustion partly escape, and are partly driven out by the second inward stroke. I say partly, for a considerable clearance space, equal to 0·38 per cent. of the whole cylinder volume, remains unexhausted at the inner end of the cylinder. When working to full power, only one stroke out of every four is effective; but this engine works with only 18 to 22 cubic feet of gas per horse-power. Up to the present time I am informed that about 18,000 of these engines have been manufactured. Several other compression engines have been introduced, of which the best known is Mr. Dugald Clerk's, using about 20ft. of Glasgow cannel gas. It gives one effective stroke for every revolution; the mixture being compressed in a separate air-pump. But this arrangement leads to additional friction; and the power measured by the brake is a smaller percentage of the indicated horse-power than in the Otto-Crossley engine. A number of gas-engines—such as Bisschop's (much used for very small powers), Robson's (at present undergoing transformation in the able hands of Messrs. Tangye), Korting's, and others—are in use; but, so far as I can learn, all require a larger quantity of gas than those previously referred to.

I have all along spoken of efficiency as a percentage of the total quantity of heat evolved by the fuel; and this is, in the eyes of a manufacturer, the essential question. Other things being equal, that engine is the most economical which requires the smallest quantity of coal or of gas. But men of science often employ the term efficiency in another sense, which I will explain. If I wind a clock, I have spent a certain amount of energy lifting the weight. This is called "energy of position"; and it is returned, by the fall of the weight, to its original level. In the same way if I heat air or water I communicate to it energy of heat, which remains potential as long as the temperature does not fall, but which can be spent again by a decrease of temperature. In every heat-engine, therefore, there must be a fall from a higher to a lower temperature, otherwise no work could be done. If the water in the condenser of a steam-engine were as hot as that in the boiler, there would be equal pressure on both sides of the piston, and consequently the engine would remain at rest. Now, the greater the fall, the greater the power developed; for a smaller proportion of the heat remains as heat. If we call the higher temperature T and the lower T′ on the absolute scale, T − T′ is the difference; and the ratio of this to the higher temperature is called the "efficiency." This is the foundation of the formula we meet so often: $E = \frac{T - T'}{T}$ A perfect heat-engine would, therefore, be one in which the temperature of the absolute zero would be attained, for $\frac{T - O}{T} = 1$ per cent. This low temperature, however, has never been reached; and in all practical cases we are confined within much narrower limits. Taking the case of the condensing engine, the limits were 312° to 102°, or 773° and 563° absolute, respectively. The equation then becomes $\frac{773 - 563}{773} = \frac{210}{773}$ or (say) 27 per cent. With non-condensing engines the temperatures may be taken as 312° and 212°, or 773° and 673° absolute, respectively. The equation then becomes $\frac{773 - 673}{773} = \frac{100}{773^\circ}$ or nearly 13 per cent. The practical efficiencies are not nearly this; but they are in about the same ratio, $\frac{27}{13}$; and if we multiply the theoretical efficiencies by 0·37, we get the practical efficiencies, say 10 per cent. and 5 per cent., and it is in the former sense that M. Witz calculated the efficiency of the steam-engine at 35 per cent.—a statment which, I own, puzzled me a little when I first met it. These efficiencies do not take any account of loss of heat before the boiler. In the case of the gas-engine the question is much more complicated on account of the large clearance space, and the early opening of the exhaust. The highest temperature has been calculated by the American observers at 3443° absolute, and the observed temperatures of the exhaust gases was 1229°. The fraction then becomes $\frac{3443 - 1229}{3443} = 64$ per cent. If we multiply this by 0·37, as we did in the case of the steam-engine, we get 23·7 per cent., or approximately the same as that arrived at by direct experience. Indeed, if the consumption is, as stated sometimes, less than 18ft., the two percentages would be exactly the same. I do not put this forward as scientifically true; but the coincidence is at least striking.

I have spoken of the illuminating power of the gas as of importance; for the richer gases have also more calorific power, and an engine would, of course, require a smaller quantity of them. The heat-giving power does not, however, vary as the illuminating power, but at a much slower rate; and, adopting the same contrivance as that on which the absolute scale of temperature is formed, I would suggest a formula of the following type: $H = C(I + K)$, in which H represents the number of heat-units given out by the combustion of one cubic foot of gas, I is the illuminating power in candles, and C and K two constants to be determined by experiment. If we take the value for motive power of the different qualities of gas as given in Mr. Charles Hunt's interesting paper in our *Transactions* for 1882, C might, without any great error, be taken as 22 and K as 7·5. With Pintsch's oil gas, however, as compared with coal gas, this formula does not hold, and C should be taken much lower and K much higher than the figures given above; that is to say, the heating power increases in a slower progression. The data available, however, are few; but I trust Mr. Hartley will on this, as he has done on so many other scientific subjects, come to our aid.

I will now refer to the valuable experiments of Messrs. Brooks and Steward, which were most carefully made. Everything was measured—the gas by a 60-light and the air by a 300-light meter; the indicated horse-power, by a steam-engine indicator; the useful work, by a Prony brake; the temperature of the water, by a standard thermometer; and that of the escaping gases by a pyrometer. The gas itself was analysed, and its heating power calculated from its composition as 617·50. Its specific gravity was 0·464, and the volume of air was about seven times that of the gas used (or one-eighth of the mixture), and was only 11½ per cent. by weight more than was needed for perfect combustion. The results arrived at were as follows:—

| | |
|---|---|
| Converted into indicated horse-power, including friction, &c. ............... | 17·0 |
| Escaped with the exhaust gas ......... | 15·5 |
| Do. in radiation ............... | 15·5 |
| Communicated to water in the jacket | 52·0 |

It will thus be seen that more than half of the heat is communicated to the water in the jacket. Now, this is the opposite of the steam-engine, where the jacket is used to transmit heat *to* the cylinder, and not *from* it. This cooling is rendered necessary, because without it the oil would be carbonised, and lubrication of the cylinder rendered impossible. Indeed, a similar difficulty has occurred with all hot-air engines, and is, I think, the reason they have not been more generally adopted. I felt this so strongly that, for some time after the introduction of the gas-engine, I was very cautious in recommending those who consulted me to adopt it. I was afraid that the wear and tear would be excessive. I have, however, for some time past been thoroughly satisfied that this fear was needless, as I am satisfied that a well-made gas-engine is as durable as a steam-engine, and the parts subject to wear can be replaced at a moderate cost. We have no boiler, no feed pump, no stuffing boxes to attend to—no water gauges, pressure gauges, safety valve, or throttle valve to look after. The governor is of a very simple construction, and the slide valve may be removed and replaced in a few minutes. An occasional cleaning out of the cylinder at considerable intervals is all the supervision that the engine requires.

The very large percentage of heat absorbed by the water-jacket should point out to the ingenuity of inventors the first problem to be attacked—viz., how to save this heat without wasting the lubricant or making it inoperative; and in the solution of this problem I look for the most important improvement to be expected in the engine. The most obvious contrivance would be some sort of intercepting shield, which would save the walls of the cylinder and the rings of the piston from the heat of the ignited gases. I have just learned that something of the kind is under trial. Another solution may possibly be found in the employment of a fluid piston; but here we are placed in a dilemma between the liquids that are decomposed and the metals that are oxidised at high temperatures. Next, the loss by radiation—15 per cent.—seems large; but this is to be attributed to the fact that the inside surface of the cylinder is at each inward stroke exposed to the atmosphere—an influence which contributes to the cooling necessary for lubrication. The remaining 15 per cent., which is carried away by the exhaust, is small compared with the proportion passing away with the exhaust steam of a high pressure, or the water of a condensing engine. As the water in the jacket can be safely raised to 212° Fahr. the whole of the jacket heat can be utilised where hot water is required for other purposes; and this, with the exhaust gases, has been used for drying and heating purposes.

With such advantages, it may be asked: Why does not the gas-engine everywhere supersede the steam-engine? My answer is a simple one: The gas we manufacture is a dear fuel compared with coal. Ordinary coal-gas measures 30 cubic feet to the pound; 1,000 cubic feet, therefore, weighs 33lb.; and taking the price at 2s. 9d. per 1,000 cubic feet, it costs 1d. per lb. The 30 cubic feet at 6,300 give 190,000 all available heat. Although good coal may yield 14,000 units by its combuston, only about 11,000 of these reach the boiler; so that the ratio of the useful heat is $\frac{11}{19}$. The thermal efficiency of the best non-condensing engine to that of the gas engine is in the ration $\frac{4}{22}$. Multiplying together these two ratio, we get $\frac{11}{19} \times \frac{4}{22\frac{1}{2}} = \frac{44}{428}$. That is, speaking roughly, 1lb. of gas gives about ten times as much power as 1lb. of coal does in a good non-condensing engine. But at 18s. 1d. a ton we get 10lb. of coal for 1d.; so that with these figures the cheapness of the coal would just compensate for the efficiency of the gas. As to the waste heat passing away from the engine being utilised, here the gas-engine has no advantage; and, so far as this is concerned, the gas is about eight times dearer than coal. The prices of gas and coal vary so much in different places, that it is hard to determine in what cases gas or coal will be the dearer fuel, considering this point alone.

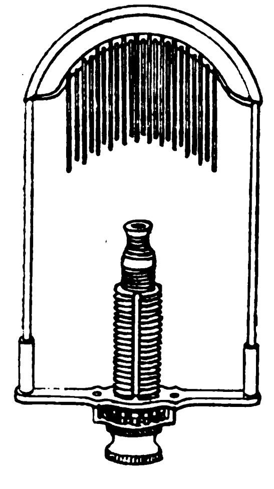
But there are other kinds of non-illuminating gases—such as Wilson's, Strong's, and Dowson's—which are now coming into use; and at Messrs. Crossley's works you will have an opportunity of seeing a large engineering factory employing several hundred mechanics, and without a chimney, in which every shaft and tool is driven by gas-engines supplied by Dowson's gas, and in which the consumption of coal is only 1·21b. per horse-power. The greatest economy ever claimed for the steam-engine was a consumption of 1·6lb., and this with steam of very high pressure, expanded in three cylinders successively. Thus in a quarter of a century the gas-engine has beaten in the race the steam-engine; although from Watt's first idea of improvement nearly a century and a quarter have elapsed.

As regards the steam-engine, it is the opinion of competent authorities that the limits of temperature between which it works are so restricted, and so much of the heat is expended in producing a change of state from liquor to vapour, that little further improvement can be made. With respect to gas-engines, the limits of temperature are much further apart. A change of state is not required, and so very great improvement may still be looked for; and it is not impossible that some of the younger members of our body may live to see that period foretold by one of the greatest of our civil engineers—that the happy time when boiler explosions will be matters of history—that period, not a millennium removed by a thousand years, but an era deferred perhaps by only half a dozen decades, when the use of the gas-engine will be universal, and "a steam-engine can be found only in a cabinet of antiquities."

## THE WATER-GAS INCANDESCENT LIGHT.

THE following description of the Fahnebjelm water-gas incandescent light, which has lately been utilised with much success in Germany, is contained in a paper read by Prof. R. W. Raymond, of New York, before the American Institute of Mining Engineers:—

The idea of obtaining light from incandescent solids is not new; nor is it new to make such bodies incandescent by holding them in a heating flame. But the successful combination of the right substance and form of the body to be heated with the right kind of flame, and the right means of adjustment, has not, to my knowledge, been accomplished heretofore; and it seems to me that the water-gas incandescent light of Mr. Otto Fahnehjelm, of Sweden, in which these objects appear to have been secured, is destined to become both famous and useful. The first fact upon which this invention is based is the intense temperature of the flame of water-gas. The combustion of this gas through an ordinary coal-gas burner, without blast or aid of any kind, will melt platinum wire. The next important basis of the invention is the form of the incandescent body. This is shown in the accompanying cut, which represents an ordinary fantail gas-burner, fitted with the necessary apparatus for producing the new incandescent light. A frame, movable by means of a screw up and down along the burner, carries at its two extremities sockets to receive two iron wire standards, which carry a curved back, provided with two rows of long teeth. By turning the screw, these teeth can be brought as near the tip of the burner as may be desired. They are composed of magnesia, which has been first baked at a high temperature, then ground, and then moulded under high pressure, and with some agglutinated material, such as starch. The flat flame of the water-gas passes up between the two rows of vertical teeth, which thus receive its greatest heat, and do not come into contact with its comparatively cooler interior. They become immediately and beautifully luminous, with a perfectly white light, which does not, like gas or candle light, change the daylight appearance of colours, and which can even be used for photographing. It is steadier than the incandescent electric. The flickering of the gas flame (which is non-luminous, and, when the comb is glowing, quite invisible) does not at all affect the steadiness of the light. If the gas is blown out, or if, by the use of a cock without a stop, it is turned off and then unwittingly on again, no evil results can follow in this case, for the comb goes on glowing for several seconds, and the gas consequently relights itself. The magnesia teeth have before use the appearance of starch. When thoroughly well prepared, they should possess considerable strength. The best that have been made thus far, I believe, would sustain eight ounces avoirdupois hung from the middle of the needle which was laid across supports 1in. apart. Since the diameter is less than $\frac{1}{16}$in., this indicates a good degree of strength. The needles are held in a composition of plaster of Paris, which fills the curved back of the comb. This back, like the side wires, is of iron; and the whole comb, with its side wires, costs about three cents. Apart from accidental breakage, such a comb endures from 80 to 150 hours incandescence before it must be removed. The first effect of the high white heat upon the needles is to make them translucent, like porcelain. Probably this change is really a condensation, fusing into a continuous mass what had previously been but a compressed aggregate of particles. The result is a gradual shortening of the needles, so that after about 15 hours it is necessary to turn the screw and bring the comb down towards the flame. This process is repeated from time to time, until at last the needles have become so short that the iron back would be in danger from the flame if they were brought fairly into it. Then the comb must be taken out, and a new long-toothed one substituted. Exact photomeric and economic tests have yet to be made under American conditions, and for water-gas produced by different processes. Speaking in a general way, I should say that the quantity of pure water-gas required to produce a given amount of light by this system is about four-fifths (in volume) the quantity of carburetted water-gas, like the Tessié gas of the Municipal Company of New York, required to give the same amount of light. The cost of the non-carburetted water-gas is, of course, much smaller. It can be sold to large profit for 50 cents per thousand cubic feet. We have, then, in this invention, a light which is actually much cheaper than ordinary gas light, while in quality it equals, and in steadiness, uniformity, and simplicity of management far surpasses, the electric incandescent light.



## THE PROPER CARE AND USE OF MICROSCOPE LENSES.*

By William Wales.

HOWEVER good the lenses of an instrument may be, they will not do their best work except when properly cared for and properly used. Yet I have met with reputable microscopists who do not in practice appreciate this obvious truth. Let me show you how a lens is cleaned. My implements are four—an old, soft, silk handkerchief, a small stick of soft wood, a phial of alcohol, and a watchmaker's glass of two powers. I have here an eyepiece. I will first examine it with the magnifying glass, by reflected light, to learn its condition. If it be found to need cleaning, alcohol is to be applied with the handkerchief. This liquid must not be allowed to touch the lacquer; but the cell which holds the lens will not be harmed by it, since that has been burned black with acid. If, after the cleaning, fibres from the cloth be found adhering to the lens, they may be blown off by a quick breath.

I have brought an objective which was sent to me to be cleaned. I will attach it to an instrument, and will place under it a slide of familiar diatoms. Now view the object through the lens. It looks so obscure that you will all exclaim, "Well, this is a very poor objective;" whereas it is of excellent quality, as you shall presently see. In it are eight pieces of glass. The back combination is composed of two crowns and the flint; the middle, of a double-concave flint and a double-convex crown; the front, of two crowns, with a flint between them. It has, probably, not been cleaned for twenty years. Suppose your watch to have been thus neglected! I will now clean this objective. I begin the work by unscrewing the cells. I then moisten a part of the handkerchief with alcohol, and with the help, if needed, of the stick of wood in searching the corners, carefully clean each combination, and I then screw each cell back accurately to its place. The work is now finished, and I will attach the objective again to the microscope, and will again ask you to view the slide of diatoms through it. The dimness is now, you perceive, all gone. Indeed, you can hardly believe it the same objective; and you have ocular proof that cleanliness is essential to the best performance of a lens, and are witnessing an instance of the dependence of important results on attention to little things.

Several years ago, while I was getting ready to visit England, the owner of a Powell and Lealand objective wished me to take the lens to its makers for correction or exchange. "It is a poor lens," he said. I could not credit his statement, for I knew the work of the Messrs. Powell and Lealand to be faultless. I called on those gentlemen. We examined the objective together, and discovered on one of the combinations a film of some substance which could not be removed except with alcohol. In five minutes the lens was clean and in perfect order; and to this day the owner refuses to believe that the lens which I brought back to him is the same that I took abroad. Never trust the cleaning of your objectives to the brass-worker, or to any person who does not know how carefully a lens ought to be handled. The brass-worker will polish the outside of the objective, but will get the lenses out of centre. To my great disgust, I once found a brass-worker subjecting one of my 4-10th-inch lenses to that treatment. I asked, "What are you doing with that objective?" "Putting it in order at the request of its owner," he said; "he wants to sell it." Taking the lens, I cleaned it for him without charge. A camel's-hair brush can neither completely nor safely remove the film of dust with which the exposed surface of the back combination of an objective is sometimes found to be coated. It will make a series of rings on the surface of the lens, and it may, if grit be present, scratch the glass. Nor should the handkerchief, either wet or dry, be introduced into the tube of any but a low-power objective. The cells must first be unscrewed from their mountings, and then the cleaning can be done properly. But, let me add, an objective ought never to be taken apart by anyone but its maker. He has the lathe upon which it was made, and he alone, when the parts have been separated, can replace them in their original adjustment to the optical centre. Any other person will be likely to screw in the cells either too tightly or not tightly enough, and will thus throw the combinations out of their necessary delicate relation to one another. Besides, unless skill and care be exercised in screwing the parts together, the front and the middle combinations will sometimes be brought in contact, and the flint glass, which is very thin at the centre, will be broken. The screw-thread of the cells is very delicate. Yet some persons, after failing to catch it, apply force enough to break it. Such carelessness passes comprehension.

---

* A paper read before the New York Microscopical Society.

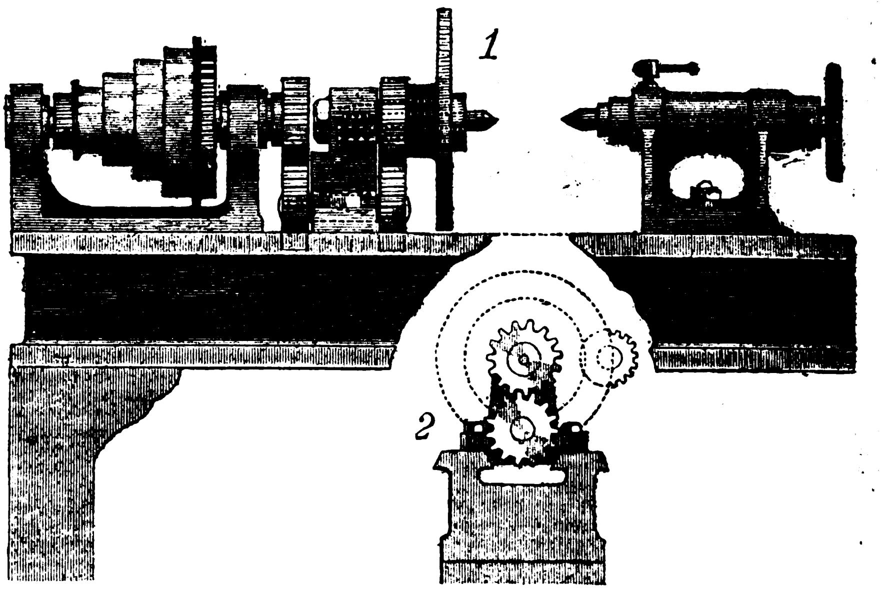
A large angle oil-immersion lens gets out of order easily. If you find the definition of such objective to have lost its sharpness, you may know that the front lens is out of centre. It has come in contact with the slide. A very slight pressure is sufficient to work the mischief. This susceptibility to injury is unavoidable, as every optician will tell you. It is incident to the requirements of high-angle construction. A few days ago an objective was sent to me with the request that the front lens should be reset. It had in some way been forced out of its place. I reset it as well as I could. But that objective, even if it had been repaired by its makers, the Messrs. Powell and Lealand, can never be what it was before the injury. The only way of repairing it was by inserting a ring of cement which, projecting slightly through the shoulder, necessarily cut down the angle. A heavy shoulder means, of course, a low angular aperture. A novel method of using an immersion lens came under my notice recently. A water-immersion objective had been ordered. It was made and sent, but it did not give satisfaction. I inquired by letter, "In what way do you proceed to work with it?" "I fill it with distilled water, and then screw it to the instrument," was the reply. An objective is sometimes almost ruined through sheer carelessness. I made a costly lens for a New York optician. He tossed it several times in his hand, and finally dropped it upon the floor. "Oh," he said, "that will not harm it!" I looked at it, and found the front combination tilted at an angle of about 45°. This act of carelessness cost that optician twenty-five dollars.

I have here the back setting of a 1½in. lens which was made by me several years ago. The purchaser of the lens had screwed it so tightly to his microscope that he could not, with his hand, unscrew it. So he used a pair of heavy gasfitter's pliers, and succeeded in pulling the tube of the fine adjustment out of the body of the instrument. This rude handling damaged the microscope to the amount of forty-five dollars. Quite recently the owner of an instrument which cost three hundred and fifty dollars told me that he had a wonderfully clever son. "Why," he exclaimed, "he has, with a screw-driver, taken the microscope all apart! He is unable, however, to put it together again." This outrage illustrates the incapacity of some people, old as well as young, to appreciate the products of fine workmanship. I do not favour the nose-piece. If you must have one, choose one that is of good design and thoroughly well made. Lenses, especially those of high power, ought not to be tested with the use of this accessory. A superior lens, worked by an illustrious microscopist, becomes its maker's best advertisement. But when it falls into the hands of a careless or incompetent person, and is not carefully used or regularly and properly cleaned, to hold the maker responsible for its consequent unsatisfactory performance is to do him great wrong.

## PREVENTING COLLISIONS WITH ICEBERGS IN A FOG.*

By PROF. GRAHAM BELL.

THE recent accident to the steamer *City of Berlin* emphasises the importance of devising practical methods of ascertaining the proximity of icebergs in a fog. The precautions adopted by Captain Laud, though they saved the lives of more than fourteen hundred passengers, and prevented serious damage to the vessel, did not prevent contact with the berg. Even the "lookouts" were unaware of the proximity of the iceberg until it was actually upon them. Under these circumstances, the method proposed by Mr. Frank Della Torre, of Baltimore, deserves consideration. His experiments indicate the possibility of obtaining an echo from an iceberg when in dangerous proximity to a ship. Mr. Della Torre believes that even an object offering so small a surface as a floating wreck may in this way be detected during a fog in time to prevent collision. However this may be, it is certain that his method is worthy of careful trial at sea, and that preliminary experiments recently made in the presence of Professor Rowland, of Johns Hopkins University, and the present writer, have demonstrated the feasibility of producing well-marked echoes from sailing vessels and steamboats at considerable distances away. These experiments were made on the River Patapsco, near the head of Chesapeake Bay, at a point about seven miles from the city of Baltimore. The party proceeded down the river in a steam launch to the selected place, where the distance from shore to shore appeared to be about three miles. The launch was kept so far from land as to prevent the possibility of mistaking an echo from the shore for one produced by a passing vessel. The apparatus employed consisted of a musket, to the muzzle of which a speaking trumpet had been attached. This gun was aimed at passing vessels, while blank cartridges were fired. After a longer or shorter time, according to the distance of the vessel, an echo was returned. The ordinary river steamboats, and schooners with large sails, returned perfectly distinct echoes, even when apparently about a mile distant. At shorter distances the effects were, of course, still more striking. In order to test the effects under the most disadvantageous circumstances, blank cartridges were fired in the direction of an approaching tugboat. The surface presented was, of course, much smaller than if the boat had presented its broadside to the launch. As the boat approached bow on, it corresponded to a target somewhere about 6ft. square, presenting a convex surface to the impinging sound wave. Even in this case a feeble echo was perceived when the boat was at a considerable distance (estimated to be nearly one-quarter of a mile). That any echo should have been perceived at all under such circumstances was a surprise. The sound was heard only by the closest attention, but in the case of larger vessels the effects were very distinct and striking. Experiments were made which demonstrated the fact that the speaking trumpet attached to the gun was of material assistance in giving direction to the sound impulse, and in intensifying the audible effect. Mr. Della Torre claims that a steam whistle or siren, combined with a projecting apparatus like a speaking trumpet, will prove as efficient as the gun. During the experiments on the Patapsco River, a curious rumbling effect, like the rolling of thunder, was often observed, which continued for some seconds. A similar sound was also noticed, as an echo from a well-wooded shore; but the effect alluded to above could not have been due in any way to the land, as the sound commenced immediately upon the firing of the gun, whereas the shore was distant at least a mile or a mile and a half. The sound was probably due to the presence of ripples on the surface of the water, as the effect was much less marked when the surface was smooth. Such a sound might prove a disturbing element of importance in a rough sea, but would hardly be sufficient to prevent the detection of an echo from a large iceberg. Had shots been fired periodically from the bow of the *City of Berlin*, it can hardly be doubted that the presence of an obstacle ahead would have been discovered in time to prevent the collision that actually occurred.



## HAMPSON'S DEAD-CENTRE FOR LATHES.

THE invention herewith illustrated relates to an attachment to any lathe for turning wood or metal, by which it can be changed from a live-centre or revolving centre lathe to a dead-centre lathe. Fig. 1 is a side view of a lathe provided with this attachment, and Fig. 2 is an end view of the lathe bed and a front view of the attachment.

In place of a face plate on the end of the spindle is a spur wheel, which gears into another wheel of the same size, placed just below the first. A standard, resting upon and fitted to the lathe bed, carries a shaft, on one end of which is the second spur wheel. A third spur wheel is fastened upon the opposite end of the shaft, and meshes with a fourth wheel (the wheels are all alike) upon a cylindrical pin forming the forward part of a stud fitted conically in the standard; this stud is placed perfectly in line with the centre of the spindle and centre of the tail stock. The fourth wheel is secured to a face plate, and both are kept in place by a shoulder on the front end of the pin. Conically fitted in the stud, which is stationary, is a centre, whose point is in line with the centre in the tail stock. When the lathe is set in motion, the face plate revolves in the same way as if it were fastened to the spindle in the usual manner. Both centres are now stationary, and anything turned on the centres must run perfectly true when reversed on them. The standard, being only bolted to the lathe bed, can be removed with the gears, and if a face plate is put on the spindle in place of the spur wheel, and a centre inserted in the spindle, the lathe is reduced to a live-centre one; while, by replacing the standard and gears, a dead-centre lathe may be formed. The use of this attachment insures the accuracy of the work, since both centres stand still, while the piece being turned revolves, and although the piece may be reversed, it will always run true on the centres. All trouble caused by a spindle running untrue is thus avoided. Further particulars regarding this invention can be obtained from the patentee, Mr. Joseph Hampson, of Newburg, N.Y.—*Scientific American.*

## WATER-CHAMBERS IN SHIPS.

THERE have been added to the exhibits of the Lords of the Admiralty in the Queen's-gate Annexe at the Inventions Exhibition two models prepared for the purpose of illustrating the use of the motion of water within a ship to moderate the disturbing influence of the waves on vessels having a large natural stability. It was in experiments made with a model of the *Inflexible*, where the great metacentric height the designers had been driven to accept threatened heavy rolling among certain waves, that this mode of quelling the rolling was discovered. The models representing sections of ships, one with, the other without, a water-chamber, are so mounted as to be easily made to oscillate in imitation of the roll of a ship at sea, and if the two models are inclined to the same angle and then allowed to oscillate freely it will be found that the one to which a water-chamber is fixed very quickly comes to a state of rest, while the other continues to roll for many minutes.

Mr. Froude, in the valuable series of experiments he made in the investigation of the subject, found that there is a certain depth of water in the chamber which gives the *maximum* effect, this being dependent upon the width of the chamber and the period of the ship. With this depth of water the growth of resistance to rolling begins almost at zero of angle, whereas with either a greater or less depth there is practically no resistance at all due to the water up to a certain angle, which angle increases with increase of departure from the proper depth. At larger angles of roll, however, the disadvantage of departure from the proper depth of water is not marked. Lastly, he observed that the resistance of water in a chamber does not increase at all uniformly with increase of angle of roll, but increases rapidly at first and at the larger angles becomes more nearly constant for all angles. A comparison was made with the steadying effect, obtained from bilge keels, with the result of showing that, while an addition of 2ft. to the breadth of the bilge keel added, in round numbers, two-thirds to the existing extinguishing power of hull and bilge keels on the *Edinburgh* at all angles of rolling, the fully-extended water-chamber added at 3° of roll about six times, and at 5° about three times that power. At 12° the chamber added no more than 2ft. of bilge keel, while at 18° it only added half as much. It is, therefore, evident, as Mr. Froude has pointed out, that while both are valuable, the water-chamber is, for most kinds of service, much the more valuable of the two. Explaining the cause of the phenomena in his report, he said:—"The extinguishing or quelling effect of water depends, of course, *cæteris paribus*, upon the value of the moment represented by the transference of water from side to side—*i.e.*, with a given quantity of water, upon the distance moved by its centre of gravity. This distance increases with increase of angle of roll, and consequently the extinction similarly increases up to a certain point, where we appear to have approximately reached the *maximum* possible transference of water, and consequently the *maximum* extinction of which the quantity of water is capable with the dimensions of the chamber. This point occurs generally at a moderate angle, and above this angle the extinction becomes practically constant. But the extinguishing effect of the water, of course, largely depends also upon the timing of its motion from side to side, the extinction being greatest when that motion takes place most nearly at the time of extreme angle of ship—i.e., in such a manner as that the water may be as much as possible running down-hill when it is moving across, and as much as possible upon the rising side of the ship when it is stationary. If, on the other hand, the motion of the water across were to take place when the ship is quite upright, the extinction would be *nil*. It is, therefore, conceivable that for the same total degree of motion or transference of water we may have a very different degree of extinction, according to the timing of that motion. In the motion of the water energy is necessarily wasted, and it is clear that if we are dealing with a permanent condition of things—i.e., if the ship is being steadily maintained at a constant angle of roll—this waste of energy in each run of water from side to side must be exactly equal to the energy taken out of the ship in each swing by the extinction. The motion of the water may be, and generally is, of a type very wasteful of energy, the water either rushing across in a mass and consuming its energy by breaking with great violence against the opposite side, as it does at the larger angles of rolling, or, at more moderate angles, running across in a breaking wave or bore, which consumes its energy as it goes in its own internal resistance; and under these circumstances, the timing of the motion appears invariably to approach pretty nearly to that giving the *maximum* extinction for the degree of motion. But the motion of the water sometimes takes the form of a mere alternating slope of surface, or tidal swing from side to side, and here there is very little waste of energy, the energy of motion of the flow of water in one direction being converted into potential energy in the shape of a rise of water at the side, and then given out again to the water flowing back to the other side, and so on. The waste of energy in this form of motion being almost *nil*, the timing is almost exactly that appropriate to no extinction, the water being in the middle of its passage across and the surface being level when the ship is upright." It will be readily seen that the value of the chamber increases as its length in the direction of the keel of the ship increases. These water-chambers have been fitted in the Inflexible, Ajax, Agamemnon, Colossus, Edinburgh, Collingwood, Rodney, Howe, Anson, Benbow, and Camperdown, and it is stated that they will be placed in the new armoured single-barbette ships Renown and Sans Pareil.

---

* From *Science.*

**High Railway Speed in the United States.**—From the *New York Herald* of June 19th we learn that, according to its official record the Michigan Central "flyer," drawn by engine No. 415, Isaac Dyell, engineer, leaving St. Thomas last Tuesday 55 minutes late, made the run of 111 miles to Detroit, on the Canada division, in 115 minutes, eight minutes being deducted for two stops, which is said to be the fastest time ever made by a regular train. The first 55 miles were made in 57 minutes, and eight miles were made at the rate of 57½ seconds to the mile.

COAL-TAR colours, especially eosine reds, have been employed in the artificial flower manufacture. They are found to produce colic and painful spots on the skin of those employed. This is due to the lead used in the eosine colours; aluminous lakes would not be productive of those annoying affections.

PARIAN is a white cement said to be a mixture of plaster of Paris and borax. Four bushels of Parian with an equal quantity of clean sand will cover 10 yards super. half-inch thick.

# SCIENTIFIC NEWS.

THE death is announced of M. Henri Tresca, the distinguished French physicist and engineer, who was born at Dunkirk in 1814. Leaving the Polytechnic school, he entered the corps of the Ponts et Chaussées; but soon quitted the service to devote himself to scientific pursuits. In 1850 he was appointed principal inspector of the French section of the exhibition at London. He afterwards became sub-director of the Conservatoire des Arts et Métiers, and he there filled with great distinction the chair of Industrial Mechanics. During the Commune he displayed much courage in shutting the doors of the Conservatoire, and preventing the Anarchists from obtaining the cannon in the possession of the establishment. In 1865 he was created an officer of the Legion of Honour, and in 1872 he was elected a member of the French Academy. Of his numerous works may be mentioned his "Cours de Mécanique Appliquée." and his "Ecoulement des Liquides." His classical investigations into the "Flow of Solids" are well known, and are alone sufficient to mark him out as a distinguished worker in the search for knowledge.

We stated last week that Dr. Riebeck would, in the autumn, commence another voyage round the world; but, unfortunately, Emil Riebeck died suddenly at Feldkirch, at about the time the note was being written.

Mr. William Sandys Wright Vaux, F.R.S., the numismatist and Oriental scholar, died suddenly last week in his 67th year. Mr. Vaux was first employed in the department of Antiquities in the British Museum, and in 1861 became Keeper of the Coins and Medals—a post he resigned in 1870. During 1871-76 he was engaged in cataloguing the coins in the Bodleian library, Oxford, and as Secretary to the Royal Asiatic Society he did a great deal of valuable work.

It is stated that Prof. Huxley retires from the various posts he holds under Government on a pension of £1,200 a year.

The chair of chemistry at South Kensington, vacant by the resignation of Dr. Frankland, has been conferred upon Prof. Thorpe, of the Yorkshire College, Leeds; but it is understood tha the salary will in future be the same as that of the other professors—viz., £800.

Mr. W. Stroud, B.A., B.Sc., has been appointed Professor of Physics in the Yorkshire College, in the place of Prof. Rücker, resigned.

Recent colliery explosions have stirred the *Times* into the remark that the hands of the Home Secretary "cannot be too promptly and too vigorously strengthened to stay a hideous barter of human lives for cheapened blood-stained coal." Shot-firing should be prohibited in all mines of which there is the least suspicion; but the Clifton Hall disaster occurred in a district in which shot-firing is said to be prohibited except when the bulk of the workers are above ground. Explosions have occurred, too, when coal was at high prices, and the miners were said to be revelling in luxury, so that the reflection above quoted scarcely applies.

The discussion about musical pitch has recommenced in earnest, and there will probably be a lively controversy. Dr. W. H. Stone writes that on the Wednesday of the Handel Festival, with the temperature at 82° Fahr., the A of the organ and the orchestra gave 446 double vibrations per second; when the second part began the temperature had fallen to 81°, but the organ and the band had risen nine vibrations, or A 455. He suggests that the heat in the organ must have increased, probably from friction, though he notes that it had been surrounded for two hours by several tons of human flesh at an average temperature of 97° Fahr. The French normal diapason is 435 vibrations, so that the performers were called upon for much more work than they would have been if we had a lower pitch. Dr. Stone's observations were made with a Scheibler's tonometer. Mr. Best replies that Dr. Stone must be aware that the record of the tonometer is only partially correct, and that a section only of the orchestral instruments has an increased pitch, while another has a lower rate of vibration. The organ, too, rises in one part and falls in another. Mr. Best declares for what is known as the Society of Arts pitch. Dr. Stone, returning to the question, replies that the orchestra rises as a whole, and not in one section, and that the organ also rises as a whole, the flue pipes more than the reeds. The tonometer, he thinks, is more trustworthy than the unassisted ear. Dr. Stone thinks the French normal diapason is the only "standard" which can be generally adopted.

The *Times* gives an account of the new Jablochkoff auto-accumulator, which it may be hoped is more trustworthy than many of the statements made in reference to electrical matters in that journal. The battery is composed of a number of cells or shallow trays, 4in. square and ½in. deep, of impermeable carbon, in each of which is placed a small quantity of iron turnings or zinc clippings. Over these is placed a covering of thick, coarse canves, saturated with a solution of chloride of calcium, upon which is laid a row of very porous carbon tubes, about 3in. long and ⅜in. in diameter outside, which are similarly saturated. In this way a cell is formed with three electrodes, one of which oxidises, a second becomes polarised, and the third forms a positive pole with the second, the first two forming a couple with a constantly closed circuit. For service a number of these cells—nine or ten—are placed within a metallic framing, after the fashion of a voltaic pile, the bottom cell resting on a metal plate forming one of the poles. The top cell is covered with a plate of carbon to which a terminal is fixed, and this forms the other pole. The auto-accumulator produces alternately a primary and a secondary current, the latter only being employed in the external circuit, while the former serves to produce the hydrogen necessary to polarise the electrodes. This action stops as soon as polarisation is complete, and is resumed when depolarisation takes place, so that short and frequent intervals of rest are necessary for the battery to re-form itself for the production of the useful current." It will be seen that this description is different to that given by M. Jablochkoff himself, which we reproduced on p. 297. Probably the first arrangement did not work so well as he thought it would.

MM. E. and H. Becquerel have communicated to the Academy of Sciences of Paris a memoir on the temperature of the atmosphere and ground at the Paris Natural History Museum during the years 1883 and 1884. These observations form a continuation of those commenced by M. A. C. Becquerel twenty-two years since with thermo-electric apparatus invented by himself.

In reference to his experiments on the production of anæsthesia with a mixture of chloroform and atmospheric air, M. Paul Bert presented, at a recent meeting of the Academy of Sciences, a very ingenious and convenient apparatus, invented by M. Raphael Dubois, by which the quantity of chloroform and air may be regulated at will. M. Bert states that, if the patient is not addicted to spirits, he should have a mixture containing ten grammes of chloroform to a hundred litres of air, and seven or eight minutes suffice to produce anæsthesia; whereas an alcoholic subject would require ten to twelve minutes. As soon as sleep is obtained, by a special arrangement of the apparatus the strength of the mixture is reduced to six grammes to the hundred litres, which is sufficient to maintain the anæsthesia.

The committee of the Berlin Gesellschaft für Erdkunde have resolved to erect a monument to Dr. Gustav Nachtigal upon the spot where he died, at Cape Palmas. A bust of the traveller is also to be placed in the society's library. An appeal for contributions has been sent out to the German geographical societies. A monument is also projected for his native town, Stendal.

The tail of the human embryo has formed the subject of lengthened investigations by M. H. Fol, and he has recently presented an account of his work to the Academy of Sciences, Paris. M. Fol says, at an early period of development—about the fifth or sixth week—there are several distinct caudal vertebræ behind the sacrum. The embryo is then from nine to ten millimètres long, but when it attains a length of twelve millimètres the total number of vertebræ is already reduced from thirty-eight to thirty-five. At a later stage, when the embryo measures nineteen millimètres, only thirty-four vertebræ can be distinguished, the thirty-fourth being obviously made up by the fusions of the four terminal ones.

Thursday last was prize day at King's College, and on the Saturday previous the work accomplished by the students of the engineering classes was inspected by a party of engineers and others, and during the week it has been on view to the public. The work exhibited is alike creditable to the pupils and the teacher, and shows what can be done by novices under careful training. Some of the joiners' work would be considered good if turned out by a practised hand, and much of that in metal was highly creditable to the students. At King's College Workshops the students are supplied with castings, and the articles made by them are their own property, so that while we are sure to find several engines we may expect also to see some lathes in a more or less complete state. As a matter of fact this year there were several which will doubtless be treasured by their owners as long as they live. Under Prof. Shelley students obtain a sound grounding in the theory, and under Mr. Walker, the superintendent of the workshops, they acquire an amount of practical skill which would scarcely be supposed possible in the time. The evening classes in the workshops are well attended, and some of the best exhibits were the work of those who can only attend in the evening. With such institutions as King's College, not to mention others, it is matter for regret that so much has been spent on that Technical Institute at South Kensington.

Dr. A. L. Esperon, of Havannah, uses parthenin in cases of neuralgia with much success. The drug is obtained from a plant known in Cuba as bitter broom (*escoba amarga*), but its botanical name is not mentioned.

**A Big Ship.**—There is building at Rockport, Maine, the second largest sailing ship ever built in America. She will carry for lower masts four sticks of Oregon pine, which will trim up as follows: Main and fore-masts 90ft. long, 36in. diameter, and jigger 88ft. long, 28in. diameter. These big sticks were towed down from Boston by a tugboat, and were hauled out of the water by a long string of oxen. The mizzen, main, and fore masts will be square rigged, the lower and topsail yards being also of Oregon pine, while the jigger mast will be fore-and-aft rigged. The main top will be 16ft. across, and there will be room enough up there for pretty nearly the whole ship's company. A good idea of the vessel's size, and of the spread of sail she will carry, may be had from the fact that it is 185ft. from the deck to the main truck, while her lower yards are about 90ft. long.

**Range of Guns.**—In answering a question on the range of modern guns in the American Navy, the American *Army and Navy Journal* says that the ranges of modern heavy guns are not tested for extreme ranges and at high elevations. Krupp, "Experiences de Tir," No. xlvii., Meppen, 17 Août, 1883, gives the range of the 30·5cm. rifle, 35 calibres long, at an elevation of 14 deg., as 10,165 mètres. No. 44, Meppen, July 31st, 1883, that of the 26cm. rifle of 35 calibres length, with an elevation 20 deg., as 11,526 mètres; projectile, 275 kilogs.; initial velocity, 530 mètres. At Gâvre, 1880, the French 34cm. steel rifle, with an elevation 38 deg., showed a range of 12,918 mètres. The authority, Hélie Balestique II. pp. 204 and 278. The "Revue Maritime et Colonial" for May, 1885, gives the range of the new French rifled 21 cm. mortar as 3,944 mètres, with 45 deg. elevation, and 3,212 with 60 deg. elevation. In his prize essay on "Improvements in the Art of War," Military Service Institution, 1882, Colonel Lazelle reports the following ranges: — Krupp rifled 28cm. (11in.) howitzer of 1879, elevation 28½ deg., 8,000 yards; Krupp's 15cm. B L. howitzer, steel, 45 deg., 6,550 yards; 200lb. Parrott, 4,272 yards, 11 deg. 47 min. elevation. American muzzle-loader, 11in. rifle, altered, 6,038 yards with 14 deg. elevation; 8in., 9,419 yards, with 27½ deg. elevation. Of ten shots from Krupp's 4½in. field gun fired at a horizontal target 10,300 yards distant, nine were included within 18 yards of lateral deviation. The greatest effective ranges of the European field guns firing common shell is given at from 5,000 to 8,000 yards; using shrapnel shell, 3,000 to 3,800 yards. Greene gives the following ranges of Russian guns: Bronze, 9lb., 5,000 yards; bronze, 4lb., 3,800 yards; steel, 4lb., 7,000 yards. Maguire, in his "Attack and Defence of Coast Fortifications," gives the maximum range of the Krupp 15cm. and 28cm. guns with shell as 8,000 yards. None of these authors cite their authorities. The new French long-range cannon, De Bange system, sent to the Antwerp Exhibition, weighs 37 tons, is a fraction under 37ft. in length, and throws a 1000lb. projectile a distance of 12 miles 752 yards (20 kilos). The author of this new piece destined for coast defence is the ex-Colonel De Bange, now at the head of a large private firm, who is said to have retired from the service in disgust, and yet his guns, from the smallest mountain to the largest position piece, have been adopted by an ungrateful country.

# LETTERS TO THE EDITOR.

◆

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

## THE APPARENT ENLARGEMENT OF CELESTIAL OBJECTS AS THEY APPROACH THE HORIZON—SEPARATING POWER OF OBJECT-GLASSES—THE SUGGESTED LARGE TELESCOPE FOR THE ROYAL OBSERVATORY—LIGHTNING A DIFFICULTY—SUNDIALS—AN ASTRONOMICAL TELESCOPE — SCRAPING METAL SURFACES — TELESCOPIC APERTURE — SIZE OF FIELD IN AN OPERA-GLASS —WHAT IS "CREATION"?—100 TO THE INCH OF APERTURE—61 CYGNI —SEEING STARS IN DAYLIGHT—A BINARY STAR OF SHORT PERIOD.

[24416.]—IN letter 23918, on p. 30, I invited attention to some very remarkable experiments made by M. Paul Stroobant, to illustrate the cause, or causes, which he believes to be operative in producing the illusion of the enlargement of the sun, moon, and constellations as they approach the horizon. The number of *Ciel et Terre* for June 15th contains another paper on the same subject by M. F. Frenay, in which he traces this effect to the manner in which the eye is educated. The major portion of our estimates of distances, says M. Frenay, are made horizontally. A man of ordinary height 328ft. off subtends an angle approximately of 1°. At double the distance, or 656ft., he subtends an angle of only ½°. Yet, as the result of long practice and the exercise of reason, we seem to see the same sized man at both distances. When, though, we come to look up at a very high steeple things at the top look very little indeed, because practice in estimating size in a vertical direction is almost wholly wanting. For the way in which this notion is developed the reader should study the original essay itself. I have served my purpose in directing attention to it here.

In reply to Mr. Sadler's query in letter 24369 (p. 346), I am unaware whether Dallmeyer's formula, which I gave, ever appeared in print. I myself heard it from his own lips at the meeting of the Royal Astronomical Society, on May 10th, 1867, at which I happened to be present. I have to thank Mr. Sadler for reminding me of Mr. Stone's paper and the discussion which followed it, which do seem to throw a certain amount of doubt upon Mr. Knott's results. If Mr. Nelson can obtain access to Vol. XXVI. of the *R.A.S. Monthly Notices* he will scarcely fail to be interested by the perusal of Mr. Stone's essay and the report of the subsequent debate.

Mr. W. S. Franks (letter 24374, p. 347) has apparently only seen your précis of the Astronomer Royal's Report, on p. 319, and not the actual Report itself. The price quoted from Grubb's Catalogue is for a completely mounted 27in. achromatic, furnished with all possible appliances; whereas Mr. Christie's very modest demand is for an object-glass and tube only. Here are his exact words: "After careful consideration of the conditions, I have satisfied myself that an object-glass of 28in. aperture and of 28ft. focal length, could be mounted in the south-east equatoreal, in place of the present object-glass of less than half that aperture; and I have ascertained that Mr. Grubb would be prepared to undertake the construction of such an object-glass with a tube suited to the special requirements of the case, so that the telescope would be equally available for eye observation or for use with the spectroscope." It seems impossible that the Treasury can refuse the relatively small sum required for such a purpose.

The reply (56682) of Mr. Taylor, on p. 352, reminds me a little of the old woman whom the sympathising young lady recommended to try electricity for her deafness; and who after three or four shouted reiterations of the suggestion, replied, "Lor bless yer, I *was* struck by lightnin', two or three weeks ago, and it didn't do me a bit of good!"

"Rosicrucian" (query 56834, p. 354) may consult Vol. XXXVI. of the ENGLISH MECHANIC, where, on p. 316, he will find as plain a description of the method of constructing a sundial as it is in my power to give (a typographical erratum in this will be found subsequently corrected on p. 356 of the same volume). Or he may buy No. 32 of Weale's Series, "Mathematical Instruments," by Heather, published by Crosby Lockwood and Co.; or pick up Ferguson's book or Leybourn's "Art of Dyalling" at some bookstall.

"E. R. H." (query 56836, p. 354) carefully withholds the one piece of information needed by anyone who is to answer him—I mean the focal length of his object-glass, because his tube will have to be a little longer than that. He will need (several) Huyghenian eyepieces—described over and over again in these columns—for astronomical work.

"E. C. B." (query 56862, p. 355) will find some useful information in Shelley's "Workshop Appliances," published in the series of Longmans' Text-Books of Science.

Merely as a matter of course, Mr. Baird Gemmill is right in the supposition he expresses in the concluding paragraph of his letter (24390) on p. 364. In speaking of the aperture of an object-glass or mirror, its clear working aperture is invariably meant, and it is wholly illegitimate to include in such stated aperture the smallest portion of the objective cut off by its mounting, by diaphragms in the tube, or by anything else whatever.

While heartily endorsing every word that "Montmartre" says (in letter 24393, p. 365) as to the value and advantage of increased power in field-glasses for outdoor use, I cannot help thinking that he is not sufficiently alive to the importance of a large field for a glass to be employed at the theatre. Of course, if the object of the user of an opera-glass be merely to scan the features of a performer, then the higher the power he uses the better; but where (as in my own case) people are short-sighted, and require the aid of glasses to see anything at all sharply on the stage, a very constricted field becomes a nuisance, and an instrument that dichotomises every actor and actress, a weariness of the flesh. Of course, I may be told that I can see (say) Miss Connie Gilchrist's head and shoulders at one view, and her lower extremities at a second; but personally I object to taking that charming young actress by instalments as it were, in any such fashion.

I am very glad to learn from letter 24398 (p. 365) that it has been decided to accede to the request of the Astronomer Royal for a suitable telescope at Greenwich. As may be inferred from paragraph three above, I wrote what appeared on p. 346 with the words quoted by "S. R." before me; but asking for money for a legitimate scientific purpose in this country by no means always means getting it; and Mr. Christie has not yet been sufficiently corrupted by communication with his allies at Brompton to follow their evil fashion of spending money first and asking for it afterwards.

"H B. F.," letter 24408 (p. 367), must forgive me if I say that he is only evading the difficulty I suggested; and by no means meeting it. If albinos and brackish-water mollusca modified from marine forms, are "attributable to heredity by reversion," their progenitors $x$ generations back must have had white hair and red eyes, and the fluviatile type of organisations respectively. To say that a single specimen of either of these aberrant forms was suddenly "created," is to speak with an amount of assurance which is assuredly not scientific —whatever else it may be.

On reading Mr. Franks's admirable letter (24409) on p. 368, the first exclamation that rises to one's lips is, "How in the world is it that no one ever thought of this before?"

In reply to query 56893 (p. 375), 61 Cygni is a binary star of very long period. It is far from easy to say precisely what stars are visible in bright daylight with a given aperture, as so many elements enter into the perceptibility of a star when the sun is above the horizon—its distance from him among the very first. Mr. Arkwright ought to see the Pole star in sunlight of a clear day with his telescope, and he might—I do not say would—be able to pick up a 3rd mag. star at an equal distance from the sun. That, however, would be his limit in this climate. As far as I know, δ Equulei has the shortest period (at present imperfectly determined) of any binary star. The orbit may be described either in 7 or 14 years.

**A Fellow of the Royal Astronomical Society.**

## α DRACONIS—STARS IN COMA BERRNICES.

[24417.]—I REGRET to say I cannot give Mr. Gemmill (letter 24390) any information with reference to Baron de Zach's observation of this star. I may add that I have not very much confidence in the accuracy of the Baron's estimate of 2 3m., although I have no doubt it was made in good faith.

With reference to the stars in Coma, referred to by Mr. Gemmill, the following measures from the Harvard photometry may be of interest:

| Star | Measures | Estimates |
|---|---|---|
| 15 Comæ | 4·73 | 4 7 |
| 14 „ | 5·13 | 4·9 |
| 16 „ | 5 09 | 4·9 |
| 13 „ | 5·09 | 4·9 |
| 12 „ | 4·75 | 4·7 |
| 17 „ | 5·18 | 4 9 |
| 21 „ | 5·49 | 5·6 |
| 18 „ | 5·50 | 5·5 |
| 43 „ (β) | 4·38 | 4·3 |
| 41 „ | 4·89 | 4·5 |

It will be seen from the above that, according to the *measures*, 15 Comæ is the lucida; but according to the estimates it is equal to 12. With reference to 12, Smyth says (Bedford Catalogue, p. 267): "A bright star, with a distant companion in the middle of the Tresses; about 1½° south-west of the lucida." This seems to have been Webb's authority for the statement. With reference to 41 and 43, it seems worthy of notice that in Harding's Atlas 41 is 4m., and 43 5m. I found "43 considerably brighter than 41" in May, 1877, and August, 1877.

June 27. **J. E. Gore.**

### LUNAR GLACIATION.

[24418.]—IN reply to "F.R.A.S.," 24136, p. 167, I should say that the decline of lunar atmosphere was general, and not local. An atmosphere in patches, with vacuum in between, is not easy to understand.

This decline seems to have been very considerable ere yet the poles were finally surfaced, as we see them, and which would be after the termination of what I call the "erosive period," and when there would possibly be little land surface exposed, and no winds.

There would be a large circular area some 1,500 miles in diameter, on which the heating effect of the solar rays would be at a maximum, and which would slowly pass round the lunar globe, and outside of which the solar rays would produce little effect. Within it there would be a certain amount of aqueous vapour raised and diffused in the then rarefied air, which would become deposited, more or less, around the margin, and what fell to north and south would tend to remain. This is what I meant by saying that the aqueous vapour raised over equatorial seas was deposited on the poles.

The large *mares* had not then been restricted as we now see them.

These polar caps in slowly extending would have irregular margins, and bays be seen here and there, where either the water was deeper, or where heat vents retarded glaciation, and we have submarine volcanoes in our Arctic regions as proof that such are possible.

As glaciation went on the horns of these bays (as in a form like Frascatorius), would meet and inclose a lagoon. Aqueous vapour would rise off this liquid surface, and become diffused in the air; but failing in transport, be soon precipitated around the margin, to pile as a wall.

It could not travel far inland over a surface of lower temperature—thus craters and walled plains would form on the poles first, and as the cap grew in size, older formations—at any distance—would not be overlaid by newer deposit.

Some of these lagoons, as heat vents closed, would glaciate sooner than others, and if vents opened near, other, and generally smaller, lagoons would melt out segments, or in freezing over, pools be left open at the vents to form smaller rings or craterlets, as in the floor of Clavius, &c. Where these heat-vents persisted over vast periods of time, we should see repeated contraction of area and concentric rings, the floor becoming steadily deeper, as in Tycho.

The extension of the S. polar cap seems to have been along a submerged shoal, or water parting, between two seas, Nectaris and Nubium, where, as in our Andes, there had been meridional series of heat-vents, causing the chains of walled plains there seen. The Altai seems to have been the border of Nectaris at one time.

The great littoral ranges I should suppose were not laid until the glaciation of the surface had reached their vicinity. Long retarded by solar heat, this latter would, at last, assist in their formation by enabling the attenuated atmosphere to take up more aqueous vapour during the lunar day, to be deposited around during the lunar night, and these ranges would, glacier-like, slowly move out to great distances. The crest necessarily highest next the *mare*, and a higher mean temperature at the shore-foot, cause there a more precipitous form. At last these seas would glaciate by zones of irregular outline, and lagoons form here and there large and small. It would be much later than this period that moisture from vents would pile to form cones, and still later—when the outer space was a better vacuum—that aqueous vapour, ejected, would flash into haze, and fall to form the rayed nimbus.

As I understand "F.R.A.S.," the transport of the aqueous vapour would mainly be by diffusion, and not translation, until the last phase of all. I should have been glad if he had more clearly and fully specified the "difficulty" he experiences. I am at a great disadvantage in being so far off and unable to discuss these matters fully here, and apt to overlook other people's difficulties in the case.

The absence of distinct polar caps and similarity of the polar and equatorial surfacing is a negative argument that seems deserving attention, as also the co-relation between inclination of surface and brilliancy (excepting nimbi); the relation of all circular forms, from *mares* to craterlets, to each other and to one cause; the arrangement of clefts, to areas of subsidence; even the dark protruding masses seen by Dr. Klein—all appear to fall into their various places in the general argument, and assist in mutually proving it (as far as such is possible). Instead of endless detail which is unintelligible, it becomes replete with meaning; its past and present history is written there all over it, could we but make it out, as I hope we may.

I may say that lately I wrote out the theory anew, and more carefully and fully illustrated it, sending it to a geological friend, Mr. H. B. Medlicot, F.R.S., F.G S., &c., and he thinks so highly of it that he desires to send the paper to Prof. G. H. Darwin, at Cambridge. Perhaps "F. R. A. S." could get a look at it?

I feel sure that when he sees the subject more clearly as a whole, he will be both surprised and pleased. At the same time, there is, no doubt, much yet to discover and solve. It is unlikely that any theory of this kind should start complete, especially from the hands of an amateur; but, looking at the subject broadly, it seems more likely that the final surfacing is rather a cold than a heated phenomenon. *Absolutely* final it, of course, is not, as I have indicated that (by the theory) we see that gravitation is at work, levelling the most salient features. **S. E. Peal.**

Sibsagar, Asam.

### SUNSPOTS—THE WEATHER.

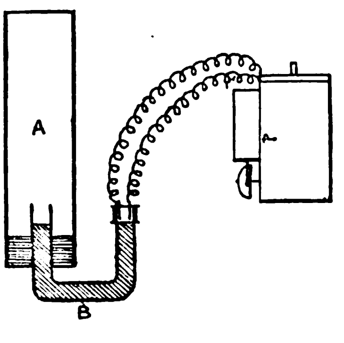
[24419.]—THE large spot mentioned in letter 24314 has again passed the sun's meridian, and has been as conspicuous as before. This time there has been a train of disturbed matter in its rear, which has, in places, broken out into spots; the "train" has been of special interest, and a study in itself. The spot would be about equal in area as previously when it passed the sun's meridian, though quite a different shape, being this time a broad, jagged gash, as it were, with a few brilliant saw-like teeth on its edges. The penumbra was not well defined; the umbra very striking in contrast with a nucleus nearly in the centre of the spot. I also thought I saw two other nuclei, one each at the narrowest part of the spot. Contrast might possibly have misled me in one of these, as there was a bright "bridge" on its edge. On the 21st a rent had been made in the penumbra, opposite to the nucleus, in the centre of the spot.

I thank Mr. Ward for his correction. What is the reason of such cold weather in June? May I be allowed to suggest that the icebergs which we are continually hearing about being in the Atlantic Ocean act as a cooler upon the Gulf Stream, and thus are reducing our temperature by the cool winds which have swept the surface of these icebergs and the Atlantic.

5, Rownsley-street, Leeds. **D. Booth.**

### DETECTION OF EXPLOSIVE GASES IN COAL MINES.

[24420.]—THINKING that some of the readers of the ENGLISH MECHANIC may be interested in the above subject, I will describe a piece of apparatus I once saw for the purpose. Suppose A to be a porous pot, as used in the Bunsen and other batteries. It should be about 8in. high and 1½in. wide, and filled with a tightly-fitting cork, preferably of indiarubber, having a ¼in. hole through the centre. Through this hole is passed one end of a bent piece of glass tube, B. At the other end of the glass tube is a small cork, having two platinum wires passed through, one at each side of the cork, and projecting into the tube about ⅛in.



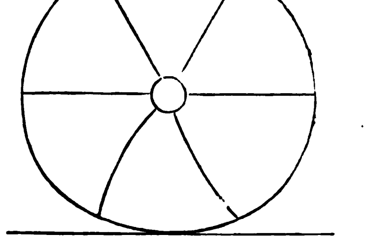
Before putting the glass tube into the cork of the porous pot, the glass tube should be filled with mercury until within a quarter of an inch of the platinum wires. The tube may now be firmly fixed into the cork of the porous-pot, and the wires from a portable electric bell connected to the two platinum wires at the end of the glass tube. On taking this apparatus into an atmosphere of hydrogen gas, the hydrogen gas will diffuse itself through the pores of porous-pot and create a pressure inside sufficient to force the mercury up the tube and make contact with the platinum wires, and so ring the bell and give an alarm.

**Jno. H. Bowman.**

### FLEXIBLE WHEELS.

[24421.]—SOME years ago, Mr. Huxley sent a design for what he called a "paradox wheel" to the "E. M." As some of your readers may remember, it consisted of a spring steel tire and four jointed spokes. The author very ably described the advantages of using such a form of wheel, and as far as I can remember, no one brought any objections against the design.

The inclosed sketch, I believe, represents an improved form of the above for light work. For a bicycle wheel, for which this form has many advantages, I propose making the tire of spring steel ¾in. or 1in. wide, and the six spokes of very thin spring steel about ⅛in. wide, or else round, whichever is found most suitable. When the weight is applied to the hub, the wheel will assume the form shown in sketch, more or less according to weight. The advantages for rough ground are too obvious to need much explanation: springs for the saddle would be quite done away with, and a brick could be ridden over without much inconvenience. If any reader thinks it worth while to make one, I shall be glad to send to his own address details of construction, if he will advertise it in the Sale Column. **S. X. Apprentice.**



### THE CASSEGRAIN.

[24422.]—"A. S. L." (25392) is certainly rather hard on our mathematical friends, and specially so on Dr. Royston Pigott; but I cannot help thinking, from the apparently unfinished state of the Doctor's last letter on the Cassegrain, that there is some cause for this over which he has had no control. There are many reasons we can easily suppose; he may be ill or have illness in his home, so I think we ought to wait patiently. At the same time I do not think the Cassegrain has had fair play either at the hands of our mathematical or practical friends who like the Cassegrain form of the reflector. This, I think, is a pity, for I am sure enough money and labour have been spent on it to have decided before now whether it will compete with the Newtonian form, and with our present mode of testing and working this could be done with certainty. It has its great advantages, and defects too, and when the Doctor has finished his articles on it, I will give a letter or two on what I consider the best and, I think, only way of overcoming some of these defects, and the best modes of practically making the two mirrors. Then the question, being fairly brought to the front, can be discussed by those who like this form of reflector theoretically with those who understand the practical difficulties of making the various parts theoretically perfect. **H. A. Wassell.**

Addenbrook Villa, Love-lane, Stourbridge.

### GAS AND GAS-ENGINES.

[24423.]—I NOTICE in your interesting leading article of last week's issue on "Gas and its Applications," the Dowson, Wilson, and Strong Gas Producers are mentioned as making a gas suitable for working gas-engines.

I cannot see why the well-known Siemens gas producer is omitted, seeing it was the first in the field, and still holds its own in the largest steel and glass works in the kingdom. It has been proved that a combustible gas is made in the Siemens producer which cannot be surpassed in quality by any other gas producer.

It also competes favourably as regards first cost, and cost per 1,000 cubic feet of gas made.

After a considerable practical experience with the Siemens producer as applied to steel-melting purposes on a large scale, I can testify to the gas made (especially that from the later types of the Siemens gas producer, where steam-blast is applied) being in every way suitable for gas-engines.

**E. W. Harvey, A.R.S.M.**

Lllanelly, June 25.

[24424.]—Noticing letter 24412, I think I have done all that can be expected already. I have no drawings of the engine, and I do not think there ever were any beyond a sketch or two to guide the pattern maker. If "Invicta" cannot call or does not like to apply at Bolsover-street, I can only suggest Bath as an alternative, with possibly a less distance to travel.

**J. K. P.**

## THE MICRO-OBJECTIVE—TO "ROB. CRUS."

[24425.]—I am sure many who read the letters of "Rob. Crus." on small lens making would be glad if he gave a few more particulars of his method of grinding and polishing the lenses, more especially the fine grinding. On page 327 we read: "It is in this fine grinding that the Pons Asinorum lies. Get over this, and the remainder of the journey is easy." Exactly so; but how are we to "get over" it? I have tried small lenses many times; but I never could get *all* the surface free from cobweb-like lines when examined with a magnifier, and the more I tried to remove them the more I put in. Should any pressure at all be used in fine grinding?

**Optical.**

## EXAMINATION OF MINERALS BEFORE THE BLOWPIPE.

[24426.]—I possess a cabinet containing 105 boxes of characteristic, and most carefully selected, minerals, which I purchased at Freiberg University in 1867. There is a German list of the boxes, without referring to which I have not the least idea what the minerals are; and I have been examining these (in perfect ignorance of their nature) by my system of pyrological analysis, beginning with box No. 1, with the view of presenting the many students who I know are "constant readers" of the English Mechanic with the methods and results of my examinations in plain English. I shall give copious foot-notes, explaining all details, and my reasons for coming to the conclusions I do, in order that the student may feel himself independent of any previous work of mine, although I presume him to have some elementary knowledge of blowpipe analysis in general, and to possess the following apparatus:—

1. A 3s. Leather Hand-blower, or a foot-blower (£1 10s.), with the necessary elastic tubing and blast-jet, &c.
2. A Pyrological Lamp, whether oil, candle, fat, or gas; if the latter, I would strongly recommend the hot-gas lamp described and figured formerly by me in "E M."
3. Thick Platinum Wire (two 2in. pieces), with the forceps necessary for holding, cleaning, and ringing (that is, making rings upon one end of it).
4. A pair of Agates, one surface of each of which is polished, capable of being placed on the table as "slabs."
5. A piece of Aluminium Plate with holder, and a few lozenges of charcoal, about ½in. square; one large piece can be sawn into these, ready for use (about 3s).
6. A pair of strong but small Crushing Forceps (1s. 6d.)
7. A good Lens (2s.)

### Re-agents.

1. Boric Acid, in white scales (3d. per oz.), in ordinary corked wide-mouthed bottle. Syn. B acid.
2. Phosphoric Acid, glacial, in sticks (6d. per oz.), in stoppered bottle. Syn. P acid.
3. Lime (clean eggshells*).
4. Oxide of Cobalt (an extremely small quantity is sufficient).
5. Potassium Carbonate (ordinary "potash") in stoppered bottle.

N.B.—In instances where I use apparatus or re-agents not mentioned above, I shall put a note of admiration (!). If the student wishes to follow me in those operations also, he must get the necessary apparatus; in my opinion, cheapest and best from J. T. Letcher, Truro, Cornwall.

(Minerals with metallic glance are first treated on aluminium plate: all others, first in boric acid before the blowpipe.)

Box No. 1.—White, Amorphous, Friable Fragments; soft.

| | |
|---|---|
| I. Powder in B acid *a*. (1.) Great effervescence, without smell; green pyrochrome (p.c.) of B acid unaltered. (2.) Amorphous, opaque, white, rounded, fragments (*c*.) (3.) Most fragments dissolve in part to transparent vitreous matter, which flows through the bead. | (1.) Sulphuric Acid: (Carbonic acid turns the green pyrochrome temporarily yellow) (*b*.)<br>(2.) Alumina: May be glucina, or contain a little silica.<br>(3.) Presence of an Alkali, which, as the green p.c. was unaltered, must be potash (confirm by II.). Soda yellows the green p.c. |
| II. Add a trace CoO (cobalt oxide). (1.) A purple suffusion spreading from the black cobalt-borate balls over the whole bead. Balls not all dissolved. | (1.) About 10 per cent. of potash. |
| III. Add equal proportion of lime to original powder, and treat the bead B.B. (1.) The whole bead a milky enamel, opaque (*d*.) | (1.) Large proportion of alumina (can't be glucina). |
| IV. Original powder in P acid, B.B. (1.) Wholly dissolved. | (1.) No silica or zirconia. |

(Time taken by a practised operator for producing the above reactions—quarter of an hour.)

Remarks.—I shall be glad of suggestions from any of your pyrological correspondents (and you have many, as "Ex-Blacksmith," "X.," Enoch Evans, &c., &c.) as to the probable name of this mineral in the subsequent issue of the "E.M."

Box No. 2.—Transparent Colourless Crystalline; but of no shape; hard.

| | |
|---|---|
| I. Powder in B acid. (1.) Transparent ice-like mass (*a*), slowly dissolving B.B. (2.) Faint yellow p.c. at first from powder at bottom of the bead; but green p.c. of B acid unchanged after. | (1.) An alkaline aluminous silicate. (2.) Trace of soda, but greater part of alkali, potash. |
| II. Powder + lime in fresh B acid B.B. (1.) Milky in part, but with lime-borate balls, not decomposed. | (1.) Not much alumina: about 15 per cent. |
| III. Added CoO B.B. (1.) Co borate dissolved as above, or rather more, to purple suffusion over the bead. | (1.) About 10 per cent., or rather more, of potash, with trace of soda. |
| IV. Fresh powder fused on AL plates, boiled, (*b*) dried, and treated in B acid, containing a trace of phosphoric acid. (1.) Undissolved, transparent, crystalline mass. (2.) Two minutes, semi-transparent balls. | (1.) Large proportion of silica. (2.) Trace of lime; here shown as calcium phospho-borate balls. |

What mineral is this?

Box No. 3.—Greyish-white, Compact, Amorphous; soft.

| | |
|---|---|
| I. Powder in B acid. (1.) Roundish, fringed, white, opaque fragments, showing very slight vitreous solution in bead; green p.c. unaltered. | (1.) Probably alumina, with large proportion of silica, and a little potash. |
| II. Added CoO. (1.) Purple suffusion, but only after long treatment before the pyrocone. | (1.) Not much potash. |
| III. Added lime (equal proportion). (1.) Milky, opaque bead, but on vesiculation (*a*) many white irregular fragments observed. | (1.) Large proportions of alumina and (probably) of silica, not glucina. |
| IV. Powder in P acid (*b*). (1.) Large transparent mass undissolved. | (1.) Large proportion of silica. |
| V. Added CoO to bead IV. (1.) Bluish purple. | (1.) Not much alkali. |

What mineral is this?

Box No. 4.—Flesh-white Laminæ; Amorphous, Compact; hardish (*c*).

| | |
|---|---|
| I. Powder in B acid. (1.) Violet p.c. from powder at bottom at first; green p.c. unaltered afterwards. (2.) Quantity of grey opaline matter with calcium-borate balls, and semi-transparent fragments. | (1.) Considerable proportion of potash. (2.) No alumina; much combined water and a good deal of lime; the rest probably silica. |
| II. Added CoO. (1.) Much dissolved to purple suffusion. | (1.) Considerable proportion of potash. |
| III. A fragment in platinum forceps (!), intumesced and frothed up before the blowpipe. | It is impossible not to perceive what mineral this is. |

Box No. 5.—Semi-transparent Fragments; soft.

| | |
|---|---|
| I. Powder in Boric acid. (1.) Great effervescence, with strong choking smell. (2.) Fragments at first, but all rapidly dissolved to a clear bead. (3.) Green p.c. totally yellowed. | (1.) Chlorine or fluorine. (2.) Large proportion of alkali. (3.) Alkali soda. |
| II. Added CoO. (1.) Rapidly dissolved to blue bead. | (1.) 25 per cent. alkali. |
| III. Added lime. (1.) Enamel, milk-white, opaque. | (1.) Large proportion of alumina. |
| IV. Look up orig. powder on B acid bead made on copper wire. (1.) No bluing of the brilliant green pyrochrome. | (1.) No chlorine. |
| V. Crushed bead of IV. with fresh powder, and boiled it in a glass bulb (!). (1.) Neck of the bulb much attacked. | (1.) Considerable proportion of fluorine. |

It is quite evident what mineral this must be.

*Notes.*—*a.* "Vesiculation, or blowing the small bead into a large vesicle or bladder about 70 times the size of the bead, as a glass-blower would (devised by me in 1867), is thus performed. The operator must have a spare mouth-blowpipe, from which the nozzle has been removed, ready at his right hand; the bead, with contents, is taken red-hot from the pyrocone by the left hand, and a moderate but rapid blast sent through the platinum wire ring from the jet before it cools." (In the "Easy Lessons," &c., which appeared in a recent volume, a picture of a "vesicle" is given.)

*b.* To make a bead of phosphoric acid (for which a separate wire should be kept, as the least trace of it very much adulterates boric acid, rendering the bead opalescent), a little of the crystalline powder which collects on the sticks should be laid upon the agate slab, a very small portion taken up on the red-hot ring as before, and held about an inch from the point of the pyrocone, until sufficient has melted on the ring to form the nucleus of a bead, which may then be plunged hot into the powder, and fused at point of the pyrocone without fear of its dropping. This is necessary from the quantity of water contained, which renders the bead very fluid until properly formed. Clean Al. plate should be underneath, and the fluid P acid (which rapidly cools there) taken up again with a clean penknife and replaced upon the ring.

*c.* This "test" is made by scraping the mineral with a penknife, and observing if the powder sounds "gritty" or soft between the agates in grinding. It only requires to be of the roughest description, not as a guide to the analysis, but to the naming the mineral afterwards.

*Remarks.*—*a.* The ringed wire, fixed in the pliers, is held for a moment at the point of the blue pyrocone, where it instantly becomes red hot. The hot ring is then dipped in a little pile of boric acid on one of the (quite clean) agate slabs; a quantity of the flakes of boric acid adhere to the hot ring, and are fused at the point of the pyrocone. This is repeated until a transparent bead, free from air-bubbles, is produced. A small fragment of the mineral is then placed on an agate between the jaws of the forceps (6) and roughly crushed. The coarse powder is then ground to fine dust between the agates, and a *very* small portion taken up at a time, on one side of the hot bead. The result of treatment of this side at the point of the blue pyrocone is then examined through the lens.

*b.* Presence of sulphur confirmed by treating the powder mixed with potash on charcoal before the blowpipe (B.B.), and placing the mass on silver with a drop of water, when a *black stain is left* on the silver. A small proportion of sulphur leaves a *brown* stain.

*c.* If there were any considerable proportion of silica here the fragments would have *fringed edges*, and not be in rounded masses—a formation characteristic of alumina or glucina only. Of these two, alumina decomposes calcium borate (contained transparent balls formed by lime added B.B.), and glucina does not. Silica or zirconia alone, or with a very small proportion of alumina, forms irregular transparent fragments with sharp edges or spikes, unless there is a considerable proportion of alkali present, when these edges are dissolved in proportion to the amount of alkali present. The presence of a large proportion of alumina may be confirmed by putting a drop of cobalt solution (!) on a fragment, and treating it B.B. when it turns blue (a discovery of Gahn); but this test will not answer in the thousands of cases where there is any metallic oxide present.

---

* A piece of these, held in platinum (!) or other forceps, is calcined before the blowpipe each time for use. I have examined the lime thus produced for phosphoric acid, from which it is absolutely free.

*d.* This milkiness is easily distinguished (by a lens) from the grey, opalescent, semitransparent bead given by lime balls in presence of silica only in B. acid, B.B., in which latter case the lime balls are *not* broken up.

2*a.* This phenomenon is a certain proof of the conclusion given: Alkali, alumina, and silica shown afterwards separately. *b.* The boiling will require a platinum or aluminium capsule (!) on an iron ring with stand, fixed over the blowpipe pyrocone. By fusing and boiling, you get rid of the alkali, and can then, by treatment in phosphoboric acid as above, get reaction for traces of lime, &c., contained in the mineral. **W. A. Ross.**

## LOGARITHMS.

[24427.]—In working out the product of $(a + b) \times (a - b)$ in numbers, by means of logarithms, I have come upon a curious result.

In eight different cases, instead of coming out $a^2 - b^2$, as one would expect, it has been exactly $a^2$.

Here is one case—

$$\text{let } a = 59{,}000,\ b = 11.$$

$$\text{I } 59{,}011 = 4{\cdot}7709330$$
$$\text{I } 58{,}989 = 4{\cdot}7707710$$

$$\text{Z } 3{,}481{,}000{,}000 = 9{\cdot}5417040$$

This last number being exactly the square of 59,000.

In the other seven cases $a$ was a number of some thousands, $b$ was a number near ten.

In each the logarithm of the product $(a + b)$ $(a - b)$ was the exact logarithm found in the table opposite the number corresponding to $a^2$. The table used had seven places of logarithms. I should like to see this odd coincidence well explained.

Rougham, June 23. **Charles North.**

## AUTOMATIC MUSICAL INSTRUMENTS.

[24428.]—The construction of these instruments is an agreeable and suitable occupation for the leisure time of persons of mechanical tastes, as no elaborate mechanism is required in their construction. But it is to be regretted that amateurs such as Mr. Pugh should not, before they begin, have thoroughly learnt and considered what they have got to do. There seems to be some misapprehension as to the distance required between the notes or air holes in the paper bands when used as a valve.

In the "Orchestrone" of Prof. Galley the holes are ⅛in. asunder and $\frac{1}{10}$in. in diameter; they are all *circular*, and are consequently cut out with a round punch.

As I have stated in my former articles, I prefer the music produced by the key or lever form of instrument best; but of course the construction is more complicated, and in making up a complete instrument the cost is nearly in proportion to the increased number of notes, as each must be made complete with its complement of valves, reeds, and attachments; but when an instrument is made so as to be applied to the existing key-board of a piano, organ, or harmonium, the mere levers and attachments required for striking additional keys do not so materially increase the work of construction. Since my former articles appeared in this journal I have made up another pianoforte player for my own use, and for this reason: The former one included six octaves, or seven keys spaced ⅛in. asunder in paper bands 9in. wide. Now, as the music is copied off just as we read it without any attempt at transposing, in many of the best pieces we had to make a sacrifice by lowering the high octave; therefore I decided to make another machine for the sake of obtaining another half-octave or four notes more. My tune-bands are now 9½in. wide, commencing at the highest G in the treble, and ending at E in the bass. This allows me ample range, as an occasional last note in a heavy chord may very well be dispensed with. As to the music to be set out for these instruments, a score is preferable when obtainable—that is to say, a concert piece including, for example, a violin and flute accompaniment; all these may be ranged in the tune or music band without any extra difficulty or material amount of time occupied in copying.

No air pressure is used in actuating my instrument, which is simple in construction. It is a kind of box about the size of a gun-case that is clamped over the key-board of the piano. Over each key is set a rod or plunger, which is held up clear of the keys by a fine spiral spring, which at the same time tilts the plungers backwards in their sockets. Along the whole length of the keys there is a finger-piece or vibrator kept in continuous oscillation by a crank attachment at its centre, or midway. The front edge of this is buffed by a thick strip of felt, and just clears the tops of the plungers as they lie inclined backwards. The equilibrium of these is so slight that the mere force of the breath is sufficient to drive them under the edge of the moving vibrator by which they are caught, and of course depressed with any degree of force. This action is all that my paper tune-band has to do; that is, select the requisite notes and tilt the corresponding plungers under the vibrator. By a simple lever the force with which each note is struck can be increased or diminished to any desired degree, and every expression is completely under the command of the performer. It might be supposed that this light action would be liable to derangement. Such, however, is not the case: it never goes wrong, and I do not even possess a test-scale to try if every note strikes, as they never miss doing so.

The length of roll or band of 600ft. mentioned by Mr. Pugh is enough to scare one. I have not yet required 100ft. I take up a well-known piece, viz., "*Faust Fantasie* (*Gounod*) *à Leybach*"—the whole of this without any omission occupies only 67ft. of cartridge paper. **F. H. Wenham.**

[24429.]—In a letter on this subject, p. 365, "A. S. L." says that a correspondent has broken his promise to send a sketch of the mechanism of the "organette," which he thinks is "somewhat simpler than that of the organina." I do not know what is to be understood by "mechanism"; but your correspondent "A. S. L." was frequently told in Vol. XXXIX. that the organette is without levers, and depends solely on perforated paper drawn over the mouths of the tubes. In these circumstances, then, I think it will be considered that Mr. Fryer has a very sufficient reason for not sending his promised contribution on the "mechanism" of the organette. If Mr. Pugh likes to take advice which is gratis, and therefore probably worth little, he will abandon his attempt to make an automatic "organ" with harmonium reeds and pressure bellows—though it is not certain whether he is attempting the "blow system" or the "suction principle." **Gray's Inn.**

## THE BREAKING OF CRANK AXLES.

[24430.]—Last week (page 268) I pointed out that there are more iron than steel crank axles in in use; since writing that letter, I have drawn up the following tabulated statement, showing at a glance the numbers on the various railways. From these figures it will at once be seen that the Great Northern, Great Western, Midland, North Eastern, and North British Companies appear to be in favour of iron cranks; the London and North Western being the most important supporter of steel.

Table showing the number of iron and steel crank axles and of straight driving axles in use on the principal lines to 31st December, 1883:—

| Railway. | Iron Crank Axles. | Steel Crank Axles. | Outside Cylinder Engines. |
|---|---|---|---|
| Furness | 6 | 112 | 1 |
| Great Eastern | 37 | 380 | 198 |
| Great Northern | 709 | 19 | 37 |
| Great Western | 1362 | 410 | 38 |
| Lancashire and Yorkshire | 573 | 356 | 8 |
| London and North-Western | — | 2174 | 137 |
| London and South-Western | 6 | 170 | 324 |
| London, Brighton, & S. C. | 90 | 329 | 1 |
| London, Chatham, & Dover | 34 | 134 | — |
| Man., Sheffield, & Lincoln | 215 | 282 | 12 |
| Metropolitan | — | — | 56 |
| Metropolitan District | — | — | 42 |
| Midland | 1453 | 232 | 16 |
| North-Eastern | 1383 | 66 | 13 |
| North London | — | 37 | 50 |
| North Staffordshire | 15 | 99 | 9 |
| South-Eastern | — | 324 | 1 |
| Taff Vale | 132 | 7 | 3 |
| Caledonian | 30 | 3 | 657 |
| Glasgow & South-Western | 13 | 264 | 13 |
| Great North of Scotland | 2 | — | 53 |
| Highland | — | 3 | 69 |
| North British | 581 | 2 | 29 |
| Great Northern, Ireland | 77 | 47 | 5 |
| Great S. and W. Ireland | — | 172 | — |
| Midland G. W. Ireland | 20 | 80 | — |
| Total of 58 minor lines | 250 | 253 | 133 |
| Total | 6988 | 5955 | 1905 |

**Clement E. Stretton, C.E.,**
**Hon. Mem. A.S. Ry. Servants.**
Leicester, June 27.

## CRANK AXLES.

[24431.]—Many thanks to W. Rowland Hart for his letter *re* Saxby's test. He is quite correct, Sir, it can be applied to crank-axles, and has just been tried experimentally. "Wilfred," p. 366, says that statistics fully bear out the truth that axles break in the webs. Will he kindly give us some of those statistics and proofs? It is just some of these facts we want to get hold of. A good many cranks have, I know, "gone" in the bearings or axle-boxes, the driving-wheel thus getting away; but the fatal spot is the web, and generally the outside web.

"Wilfred" hopes practical men will give their opinions; so I express mine most decidedly for best Yorkshire iron cranks; steel is too strong and brittle for the job. **Locomotive.**

## ACCIDENT AT MANCHESTER.

[24432.]—There has been no Board of Trade inquiry *re* the collision with stops at Manchester central. The engine was 1666, the brake the "leak-off." The case hardly wants explanation; it was only Portskewet Pier and Northampton over again —the power leaked off. **Midland.**

## HEBERLEIN BRAKE.

[24433.]—This brake on the Colne Valley is an improvement; it is kept off by a "tight cord," a principle used years ago by Wilkin and Clark, also Park and Webb. We all pretty well know how useless the cord communication is, and I should not like to trust a brake to such a poor contrivance as a cord. Suppose it sticks in a pulley, as the Clark Webb cord does, where are you? It seems this brake is not on the engine, only three coaches.

**Brake.**

## THE NEW TIME.

[24434.]—I may inform our friend "F.R.A.S.," letter 24365 (p. 346), that having observed two or three solar eclipses I am sufficiently acquainted with the phenomenon to know that an eclipse does sometimes begin "before noon" and finish "after it"; and in reply to his query as to how I "propose to surmount" the difficulty of the change of date in this particular instance, I may simply state that I should allow this difficulty (?) to remain. Why? Because a change of date being necessary during the progress of a solar eclipse is a thing that would so seldom occur, that it is really no difficulty whatever. Whereas, in the cases pointed out by me in letter 24355, p. 325, it is a difficulty; therefore, as the change of date has to be made, it becomes a matter of choosing between two evils, and its having to be made occasionally in the midst of a solar eclipse is, I consider, the least of them.

With reference to the new time having been found satisfactory for the administration of the internal work of the Royal Observatory, I may be allowed to point out that though it is the case at that establishment, it may not prove so at other observatories; on that point, however, I may say that, speaking to the Astronomer-Royal on this subject the other evening, I was pleased to learn from him that steps have been taken to ascertain whether the adoption of the new time for astronomical purposes will meet with the approval of astronomers generally.

Though personally not altogether in favour of the astromomical part of the change, I may conclude by saying that I am willing to abide by the verdict of the majority.

Forest Gate, June 23. **B. J. Hopkins.**

## THE TERRESTRIAL TELESCOPE.

[24435.]—The valuable article by Mr. E. M. Nelson on the terrestrial telescope, p. 247, in "E. M." of 22nd May, deserves the thanks of all our readers who use that instrument.

It is impossible not to sympathise with a writer who confesses to loyalty to the single tube to the extent of still carrying a 6-drawer telescope in his pocket as his constant companion.

The perusal of his interesting article made me unearth my own corresponding instrument—a 6-draw, in German silver, by Troughton and Sims —the sight of which recalled times when, some forty years ago, the height of ambition was reached by its identification of the incoming ss. *Eclipse* or *Isle of Thanet* from Ramsgate Harbour; or later on, from Malta Harbour of the *Banshee* and *Caradoc*, the Marseilles mail-boats, which could be seen at a surprising distance in that perfect atmosphere.

But when the writer asks why the public have replaced the single tube by the binocular Galilean glass, and concludes that is "because they like powers of four to eight without, in preference to higher powers with trouble," he is hardly just to the circumstances.

It is not only that the two eyes see more than twice what the single eye sees, for the binocular result is not merely A + A, but $A + A + x$, $x$ being that mysterious charm which perfect double vision possesses beyond the mere duplication of the pictures; but in addition to this advantage the Galilean glass is ready for work all round the twenty-four hours, while the telescope must be closed from dusk till dawn.

The instrument which years ago replaced the 15in. 6-draw telescope (just referred to) as my present constant companion, is the 4-power Galilean glass which fits in the ticket-pocket of all my coats, and although the telescope has a power of 15 against its 4, it is beyond question that I see a great deal more with the 4 than the 15 on account of its greater light and double grasp of the object, and also that I can, and do, use it on many more occasions than a telescope could possibly serve me in, irrespective of its being only 3¾oz., and of the fact that it is taken from its pocket, opened, focussed, shut, and returned by the action of three fingers of one hand only.

Regarding powers, Mr. Nelson finds 30 for ordinary and 40 for extraordinary bright days is as high as can be used (this, I understand, not to be per inch, but to any aperture); "50 always making the presence of the atmosphere unpleasantly conspicuous;" concluding with, "there is imposed by our atmosphere a limit to power no matter how large the aperture of the telescope." Upon this, which is quite true, it is worth remarking that exception may be made at very short distances, when almost any powers may be successfully used.

It is also true that the powers furnished by most English opticians appear to support Mr. Nelson's conclusions. On the other hand, the Paris makers who supply the French Ministry of War, furnish minimum terrestrial powers to the respectively named apertures as follows:—50 to 3in., 55 to 3¼in., 65 to 3¾in., 80 to 4¼in., and 90 to 5¼in. object-glasses. I habitually use 80 and 110 on my double telescope in Paris, and though I often see the atmosphere boil with them, I have never yet used lower power than 60 on its 3⅜ o.g.'s. (I have now, however, ordered a pair of 40's, in consequence of Mr. Nelson's article.) I cannot think that the variation in the English and French powers in use can arise from difference in atmosphere, for the heat is greater in France, and hence the boiling would be most apparent in that country. The French opticians always consider English telescopes under-powered.

Mr. Nelson gives, on page 248, an excellent device for testing the the eyepiece diaphragms; but I would ask if the formula given is not incomplete? "Unscrew e.p. cap, focus and reverse—then seek disc of light seen at e.p., keeping eye some distance from o.g." are the instructions, which should produce—not a disc of light—but a minified counterpart of the magnified picture seen before reversal. Lastly, the same extent of field was found in his 1⅛ 15-power telescope, and in his 2⅛ binocular of power 8. I would ask if 8 is not too high an estimate? I have never yet seen a so-called English made Galilean glass of power 8; and if a 2⅛ aperture has a field of 4° and a focal length of 7½in., it should give a power of 6 only.

Mr. Nelson has satisfied himself that 4¼in. is the maximum aperture for advantageous terrestrial use; but if some owners of larger glasses—which are idle all day—would study and master them as Mr. Nelson has done, we might elicit more of such interesting and useful contributions to this too little known department in optics.

**Montmartre.**

## OPERA-GLASSES OF HIGH POWERS.

[24436.]—Having been twice foiled in my attempt to get a "seven-power" field-glass at the Army and Navy stores, might I ask "Montmartre" the great favour of procuring me one? I shall send cash for glass and expenses to any address he may indicate in the "Sale Column." Should he grant my request, I would ask him to send me, not a 39s. one, but one mentioned by the store people as being "superior" at the price of £2 16s. The distance between my pupils is 2⅜in.

9, India-street, Edinburgh. **G. Dickson.**

[24437.]—What can be fairly called an opera-glass? Surely not a binocular 11in. long, 5in. wide, and 2½in. diameter at largest end. Yet these are the dimensions, when in use, of the glass that "Montmartre" (24893) says he used in the Albert Hall. Where there is one "enthusiast" that would have courage enough to display so formidable an instrument indoors, I venture to think there are 99 who would not value power so highly as to be so heavily handicapped in size and weight. I am told by the optician who has a set of glasses for comparison that, although a great number of gentlemen have been to critically compare them, the general opinion respecting "Montmartre's" recommendation (6 and 10 power glasses) is that they are not satisfactory on account of their very small field and of the great size of the large one.

There is no difficulty in making a high-power glass cheap, and so the comparison of prices is useless if field of view and definition are not taken into account. I feel sure that a binocular with object-glass 1⅝in. diameter, of five diameters magnifying power, such as sold at £2 2s., will be far and away more satisfactory for either indoor or out-door use than the 6-power with small field of view. The question of abnormally high-power opera and field glasses was settled by public opinion years ago, when, after some hundreds had been sold, they were gradually put on one side, or exchanged by the purchasers or owners for others having a larger field, because they were found to be uncomfortable to use. As an instance of how light and field of view are appreciated, and power is confused with definition, I have known persons on being shown a glass of three-diameter power with large field, plenty of light and sharp definition, say it was more powerful than one of six diameters, that they had been looking through a minute before. The explanation is not far to seek, for one produces a pleasant sensation of sight, with a clear and sufficiently enlarged image of the object, while the other is limited in view, and often (unless well-proportioned) very indifferent in definition. Without going so far as to say the high-power glasses recommended by "Montmartre" are without use, I must strongly express the opinion that where they are not to form a portion of a "battery of binoculars" (so that the owner may pick and choose for the particular purpose in hand), they are not the opera and field-glass for every-day requirements. For special out-door work, where only a large glass could be satisfactorily used, the wide-angle binoculars, or a small single telescope (1½ o.g.), of fifteen-diameter power with large field would, in my opinion, be more satisfactory.

**G. R. Baker.**

P.S.—I am informed that "Montmartre's" model glasses can be purchased, as well as compared, at address given in advertisement on front page.

**Discrimination of Butter and its Substitutes.**—Mr. Thomas Taylor, Microscopist of the Department of Agriculture, at a meeting of the Washington Microscopical Society, read a paper on some discoveries he has recently made while experimenting with butters and the various forms of butterine and oleo-margarine. He first boiled a number of samples of pure butter obtained from Maryland, New York, Ohio, and other States, for the purpose of crystallising their fatty acids. After a lapse of twenty-fours, during which time they were laid away in a cool place to crystallise, on placing small portions of each under the microscope, using cotton-seed oil as a mounting medium, he discovered that the crystals of pure butter were sometimes globular and sometimes ellipsoidal in shape, and on turning the polariser so as to cross the analyser there appeared on each a well-defined cross, having equal arms, like that known as the St. Andrew's cross, and that on rotation of the polariser the cross rotated in like manner. He found also that the crystals of butterine and of oleomargarine, beef, and swine fats, are of stellar form, and differ from each other. These do not exhibit the cross spoken of in the case of true butter, and do not follow the rotation of the polariser. In this way butters may be distinguished from olemargarine made of beef or swine fats. Dr. Taylor stated that only in fresh butter has he been able to detect the cross in perfect form, and that in butter which has been kept for some time, or butter of inferior quality, when boiled and viewed under the polariser, the crystals present a rosette form, generally four-lobed, and these rotate on the turning of the polariser as do those in fresh butter—conditions not observed in any other fatty bodies, animal or vegetable.

**Physiological Effects of Compressed Air.**—N. Suchorsky states (*Chem. Centralblatt*) that when compressed air is respired the absolute amount of oxygen inspired and of carbonic anhydride expired is diminished. The rhythm of the respiration remains unchanged. In all cases of mechanical hindrance (bronchitis), restriction of movement of the organs (pleuritis), or reduction of surface (pneumonia), the change of rhythm consists in a gradual disappearance of the pause after expiration, and the times of inspiration and expiration become equal. Compressed air acts on the circulation in a twofold manner—on the one side it compresses all the capillaries of the outer surface and of the respiratory organs, causing a more complete emptying of the veins, and on the other side changes the distribution of blood in the system, causing an accumulation in the abdominal organs. The therapeutic action of compressed air may be referred exclusively to its mechanical action on the organism, and to the increase of partial oxygen pressure. The latter produces no perceptible effect on the oxidation process in the body; on the contrary, in pathological cases where respiration is impeded, it tends to reduce the absolute amount of oxygen taken up and the carbonic anhydride expelled, as the organism obtains the necessary amount of air with less difficulty, and so the muscular work of the respiratory organs is economised. Consequently, the therapeutical application of compressed air cannot be considered as facilitating oxidation and support of the body in sick cases, but as a saving of effort. Nevertheless, it would be erroneous to conclude that compressed air might in these cases be replaced by air rich in oxygen, since the compressed air exerts a series of favourable influences on the sick organism, and especially on the respiratory organs. The pressures employed varied between 1,045 and 1,143mm. of mercury.

# REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[56257.]—**Telescope Stand.**—Read "convex" instead of "concave," which you will find in letter 56257, p. 351.—D. Booth.

[56314.]—**Strength of Gear Wheels.**—What do you mean by "swinging" 5 cwt.? If this weight is at the end of a lever, what is the *horizontal* distance between a plumb-line dropped through the centre of the weight and another dropped through the centre of the spindle? Is the weight raised suddenly or slowly?—Glatton.

[56538.]—**Ink for Black-Edged Note Paper.**—The usual method, I believe, is as follows:—Mix graphite 11 parts, common ink 22 parts, dissolved gum arabic 1 part. Then with a sponge lay the colour on the edge of the paper, previously placed in the cutting press, rub it with a piece of cloth, and burnish. The edge of the paper must be rendered perfectly smooth before applying the black.—Percy W. Stanley, 119, Manchester-road, Poplar, E.

[56550.]—**Sawing.**—Several replies have been written on wood-working tools, and I believe almost all saws have been mentioned, except pit-saws. Now, I do not wish to set aside the advice given to "Alabama" by "J. M.," but will venture, as well as I possibly can, to make clear the process of sharpening his saw. First, keep the teeth as near as possible like Fig. 1, the hook being about 30°, which will do for most kinds of wood. Fig. 2 is meant to represent the various bevels to be filed on the tops of the teeth; the harder the wood, the less the lead of the teeth, and the softer the wood, the more cant; but do not at any time, let it be more than 80° or 90°, or it tears the fibre of the wood. Most pit sawyers, when sharpening, hold the file something like Fig. 3, and the gullet of the saw is generally a long bevel, and sharp, which is of no earthly use whatever: the result is no two teeth together alike for hook or size. I maintain that a pit-saw requires to be sharpened (much the same as frame-saws, commonly known as vertical-saws), using half-round file, the round part to lower the gullet (straight through), and the flat side to top the teeth with. One of the most essential points is, saw perfectly level on top, and the set to be uniform.—A. Lester.

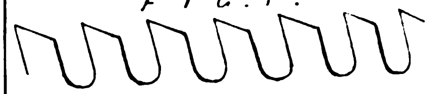

FIG. 2.

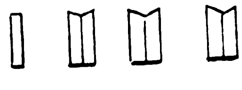

FIG. 3.

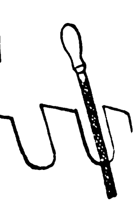


[56575.]—**Galvanometer.**—I am sorry I cannot help Mr. Bridge after perusing query 56081. I do not conceive how an astatic needle "entirely concealed from view" can be made to register or indicate its movements.—Nun. Dor.

[56591.]—**Lee-Boards to Boats (U.Q.)**—It is not a common practice to affix lee-boards to boats, and there is no rule for doing so; consequently I fear querist will have to become his own naval architect, and make and affix his lee-boards in the manner that will best attain the object he has in view. If it is to give his boat the stability and lateral resistance necessary to carry a sail, I think the contrivance thrown out as a centre-board would best attain this, and will send a sketch thereof, if querist wishes it.—James McCash Govan.

[56620.]—**Steam Carriages.**—If I understand "Progress No. 2" he must know more about what "Progress" means than I do. I gather from his last that the roads will need to be iron plated, for certainly, you know, *I* am not going to crawl along behind a coal-waggon. He will want four sets of those rails: slow and fast traffic going and returning.—Nun. Dor.

[56620.]—**Steam-Carriages.**—To "Invicta."—It is with great pleasure that I reply to our friend across the "silver streak," and assure him that anything I could possibly do to assist him I would do most freely and frankly. To (1) I would say that so far as I have had experience, the arranging of the engine into a very small space has been in the past one of the fallacies which have blocked the way. For an engine of 1 h.-p. without boiler, fitted also with reversing motion of a simple kind, and, if desired, an expansion gear as well, I should want a space of, say, 4ft. long by 12in. by 12in., or the entire engine and crank can be put into a space like a shoot, 12in. square and 4ft. long. Now the system I advocate is that of a cylinder of small diameter by comparison and long stroke, the abolition of all gearing, and the whole reduced to the utmost simplicity. Now a statement without a reason for it is entirely worthless, and I will give facts for the faith I hold. I have ridden on a steam-carriage which was propelled by a small high-speed engine; something like a space 18in. by 12in. by 12in. would cover the engine; this engine as soon as we started produced a very lively exhaust and a lot of visible steam. But worse still, it produced a vibration and throbbing of the entire carriage and the passengers therein—that to me was very unpleasant. Then the noise of the reducing gear was another objection, and altogether, although it was able to travel all right, still, it did not come up to my ideas of a motor carriage. A mechanical friend who was with me on the occasion of riding on this first motor, decided to make an entirely different one from my designs, and after some delays, due to the want of materials and tools, the machine was tried with a most satisfactory result. The connecting rod taking hold of a crank in the main axle did away with all gearing. The starting was positive, whilst the motion at a speed on a good road was, as "C. B., Zurich," says, like sailing, the speed of the engine being very moderate, there was none of the vibration or jar resultant from a quick-running engine; the exhaust could scarcely be heard or seen, whilst the demand for steam was very small. The high-speed engine mentioned had a large boiler, and was most voracious in its demands for steam, especially at every little rising grade. But, to come to the specific questions again, as point (2) the pressure would be, say, 80lb. to 100lb. on the square in., or, say, seven to eight atmospheres. (3) The piston strokes per minute would be about 110 per minute, or, say, 55 revolutions a minute only, with a speed of, say, eight miles an hour. (4) The steam used would be entirely according to the gradient; and the condition, and consequent resistance due to the surface of the road. (5) The cost of engine alone would, in my opinion, be about £20 to £30. The Parkyns engine is only suitable for a tricycle or carriage for one person, and its power is very limited. The carriage I am thinking of would carry, say, four persons up and down hill, with a weight of, say, 30cwt. Besides this the weight of the passengers would be additional. I am also writing to this gentleman direct, and hopefully anticipate that some practical result may accrue in this direction.—INVICTA.

[56646.]—**Bicycle Painting.**—If you mix the colours with turps and varnish, and they seem to "work stiff," that shows that you have not used enough. It is well to mix a "little and often," as you want them to dry quickly.—ESSAR.

[56656.]—**Planishing Tin Plates.**—You must hammer round the edges now to take out the hollow of the centre; but in future pass the punched plates between flattening rollers, and do not hammer at all.—ESSAR.

[56657.] — **Wireworking.** — It is done by machinery—weaving machines.—J. T.

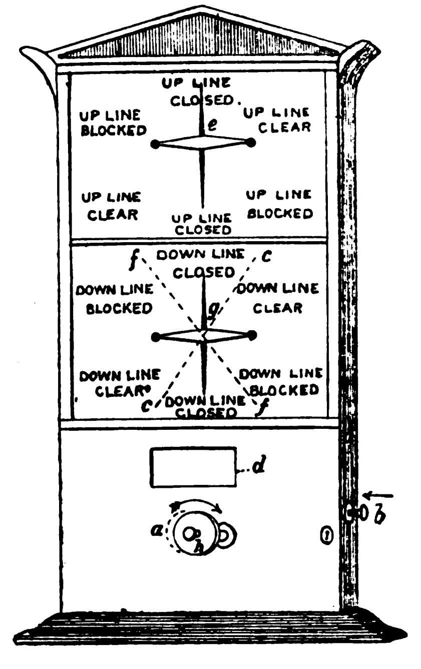
[56672.]—**Tarpaulin.**—Paint it with the required colour pigment mixed in "double boiled" oil, very thin coats, and allow to dry thoroughly between each.—NUN. DOR.

[56676.]—**Free Reeds.**—A so-called reply to this query appeared on pp. 288, 289, which concluded by showing that the writer did not understand the question he had set out to answer; and as in most other instances of the kind, presumption followed ignorance, and the querist was told to "discard the somewhat foolish ideas expressed in the query." The "foolish ideas" are suggestions for making a tuning bellows—an apparatus which Mr. Fryer may now learn is used when filing reeds up to pitch. It has nothing to do with "learning the art of tuning." The least Mr. Fryer can do now is to tell the querist how the bellows is constructed which is used in factories where they make harmonium reeds. The reed filer has a reed of the given pitch fitted on his bellows, and he tries the new ones until he gets them like the standard. I would suggest to the querist that the easiest plan is to use an exhaust bellows having a weight to pull down the feeder, and a treadle and strap to pull it up. Three holes are usually sufficient.—G. L. B.

[56683.]—**Magneto Machine.**—You cannot turn an electro-motor by the current generated in an ordinary form of magneto machine, nor will it ring bells unless a polarised magneto bell is employed, as in the Wheatstone A B C call bell. It would also be impossible to indicate what current an unknown armature could yield simply by the speed to be driven at: the power of the field magnets must be known and the particulars of construction of armature so as to form an idea. The best arrangement of fields is obtained in the De Meritens system, and that form of armature is one of the best and requiring little power to drive, and will ring an ordinary electric bell. There is a special magnet steel now manufactured by a Sheffield firm—cast or shear steel will not suit; good magnet steel should contain a percentage of tungsten, and the bars appear of a dull speckled character. A Belgian mechanic was in England last year who had a method of magnetising steel to a very high degree, and I believe he has formed a company in Paris for this special trade—telephone manufacturers being large users.—AJAX.

[56685.]—**Stiffening Woollen Cloth.**—Use gelatine applied very hot and thin.—T. M.

[56695.]—**Block Instrument.**—I send herewith a sketch with description of the working of the "Tell-tale block instrument" in use on the London and North-Western Railway, at Willesden Junction and other places. The normal position of the needles is as shown. "Line Closed," and no train, engine, &c., may be allowed to proceed so long as the needles stand in this position, in which position they merely show that the signalman is not in a position to accept the "Be Ready" signal for a train. The "Be Ready" for a train having been received, the signalman, if everything is clear, will accept the train by removing the needles to "Line Clear," to do which he must turn the disc A to the right (after he has pressed the plunger B, which unlocks the disc A), and the needles will then stand in direction of dotted line C C; similarly, on the train being given in section, he will press the plunger *b* once more, turn the disc A to the right again, this causing the needles to shift from "Line Clear," to "Line Blocked," as shown by the lines F F. Simultaneously with turning the disc A, the words "Line Closed" in the square *d*, will change with the needle to "Line Clear," or "Blocked," as the case may be. "Line Closed," standing on green ground, clear on white, and blocked on red. The plunger H is used only to ring the bell with, and the needle G corresponds with the needle *e* on the instrument in the box in advance, and *vice versâ*. I have worked these instruments myself, and in my opinion they are the best block instruments yet invented. I may mention they are Tyer's patent. —LEVER.



[56700.]—**Circumference of Wire Rope.**—Circumference = $3\frac{1}{7}$ times the diameter.

$$\therefore \frac{119}{1} \times \frac{3}{32} \times \frac{22}{7} = \frac{7854}{224} = \frac{561}{16} \therefore \text{diameter}$$

of rope = $35\frac{1}{16}$in.—LEVER.

[56703.]—**Algebraical Problem (No. 2.)**—Would W. J. Grey kindly explain the latter part of the equation $\frac{10}{\underline{|r}} : \frac{1}{\underline{|r-1}} :: 5 : 3$. What does he mean by the $30\ \frac{\underline{|r-1}}{r=6} = 5\ \underline{|r}$ signs $\underline{|r}$ and $\underline{|r-1}$? And how does he arrive at $r = 6$? An explanation of the above would oblige several contributors besides—EXCELSIOR.

[56703.] — **Algebraical Problem.** — Having noticed "East Anglian," J. C. Kelly, and "J. C.'s" attempts to answer "Trophy's" algebra question in the last numbers of the ENGLISH MECHANIC, will you please kindly allow me to point out that none of the answers are satisfactory, inasmuch as they do not satisfy the conditions of the problem? "East Anglian" starts with a false premise by assuming that $13\frac{1}{3}$ hours means $3\frac{1}{3}$ hours, and, of course he is out of court. Taking J. C. Kelly's figures, and assuming that $x$ = number of gallons in hold at first, $y$ = number of gallons leak per hour, and $z$ = number of gallons pumped per hour by A. we have time in which A. would pump the whole $= \frac{x}{z - y}$, or 10 hours; then by question, $3\frac{3}{4}z = 3\frac{1}{3}z + 100$, or $600 = 633\frac{1}{3}$, which is absurd. With "J. C.'s" figures we should have, as before, $\frac{x}{z - y} = 10$ hours, and $3\frac{3}{4}z = 3\frac{1}{3}z + 100$, or $90 = 180$, which is also absurd. The true answers, and which satisfy the conditions of the question, seem to be: $x = 1{,}200$ gallons, $y = 120$ gallons, and $z = 240$ gallons; for $\frac{x}{z - y} = \frac{1{,}200}{240 - 120} = 10$ hours, and $3\frac{3}{4} \times 240 = (3\frac{1}{3} + 240) + 100$, or $900 = 900$. —D. R. M.

[56722.]—**Flywheel.**—You may use a wheel 18in. diameter if it be more convenient. At 300 a minute the wheel should weigh from 40lb. to 42lb., instead of 35lb. You can get the extra weight by making the rim nearly $\frac{1}{4}$in. thicker in the major portion. If the wheel was even a little more than the theoretical weight, it would not be a matter of injury even.—INVICTA.

[56733.] — **Problem.** — In reply to "East Anglian," on page 371, I wish to state that the correct answer to problem on page 353 is arrived at as follows:—As A. takes three strokes, while B. takes two, and throws out as much water in five as B. does in four, the quantities pumped out by A. and B. in equal spaces of time are as six to five. Let $x$ = the No. of gallons in hold at first, $y$ = the hourly influx at the leak, $z$ = the time B worked = the time in which A. would clear the hold, $x + yz$ = the quantity which would be pumped out by A in two hours, $\frac{x}{z} + y$ = the quantity A. pumps out per hour, and $\frac{5}{6}\left(\frac{x}{z} + y\right)$ = the quantity B. pumps out per hour. $\frac{5}{6}(x + yz)$ = the quantity pumped out by B. $-\left(x + \frac{40}{3y}\right)$. $\frac{5}{6}(x + yz) = \frac{1}{6}x + \left(\frac{40}{3} - \frac{5}{6}z\right)y$ − the quantity pumped out by A. Also, $z : (x + yz) :: \frac{40}{3} - \frac{40}{3z}\frac{x}{z} : -x + \left(\frac{40}{3}z\right)y$ = the quantity pumped out by A. $\therefore \frac{1}{6}x + \left(\frac{40}{3} - \frac{5}{6}z\right)y = \frac{40x}{3z} - x + \left(\frac{40}{3} - z\right)y$, whence $x = \frac{yz2}{80 - yz}$. If they had both worked together they would have emptied the hold in $\frac{15}{4}$ hours, and the quantity pumped out would have been $x + \frac{15}{4}y$. $11 : 6 :: \left(x + \frac{15}{4}y\right)$ : the quantity A. would have pumped out $= \frac{6}{11}x + \frac{90}{44}y\ \frac{15}{4} : 1 :: \frac{3}{11}x + \frac{90}{44}y : \frac{8}{55}x + \frac{6}{11}y$ = the quantity A. pumps out per hour. $\therefore$ $\frac{8}{55}x + \frac{6}{11}y = \frac{x}{z} + y$; whence $x = \frac{25yz}{8z - 55}$, and $\frac{25yz}{8z - 55} = \frac{yz2}{80 - 72}$. Divide by $yz$, and $\frac{25}{82 - 55} = \frac{2}{80 - 72}$, and $z = 10$, $x = \frac{yz}{80 - yz} = \frac{100y}{10} = 10y$. But if they had worked together, A. would have pumped out 100 gallons more than he did. $\therefore \frac{6}{11}x + \frac{45}{22}y - 100 = \frac{x}{6} + \left(\frac{40}{3}\frac{5}{6}z\right)y$, in which equation put $x = 10y$, and $z = 10$; and we shall have—

$y$ = 120 gals. hourly influx
$x$ = 1200 " the quantity in the hold at first.—TROPHY.

[56744.]—**Water Softening.**—We have an apparatus that has been at work eighteen months, softening 4,000 gallons per hour, costing about $\frac{1}{4}$d. per 1,000 gallons for lime, no chemical knowledge required, and very little attendance, also a simple method of testing the hardness. We reduce the water from 18 to 5 degrees of hardness, and effect a great saving. If "J. T. C." will advertise his address, I shall be pleased to give him particulars and to show him the apparatus and test.—St. Pancras.

[56780.]—**Camping Stoves.**—Thanks for the answers to my query. I have got two large methylated spirit stoves, and am having a thin iron box made for them with holes in the top for kettle, &c., to fit in, with door in front. Would they kindly tell me where they got their drinking water from—whether they got in a supply coming along, or river water filtered? If the latter, which is the best filter to take?—W. P.

[56796.]—**Boiler.**—Surely "Invicta" must be wrong in his statement that the 2oz. weight at the end of $5\frac{3}{4}$in. lever (short end of lever $\frac{3}{4}$in., area of valve $\frac{13}{16}$ths circular in., or rather more than half of a square inch), would give a pressure of 25lb. I fail to see it. Would "Invicta" please be kind enough to show his method of working it out?—J. B.

[56823.]—**Steam.**—Cubical contents of cylinder in cubic inches—

$$\begin{aligned} &= \pi \times (\text{radius})^2 \times \text{length} \\ &= 3{\cdot}1416 \times (16)^2 \times (6 \times 12) \\ &= 3{\cdot}1416 \times 256 \times 72 \\ &= 804{\cdot}2496 \times 72 \times 57905\ 9712. \end{aligned}$$

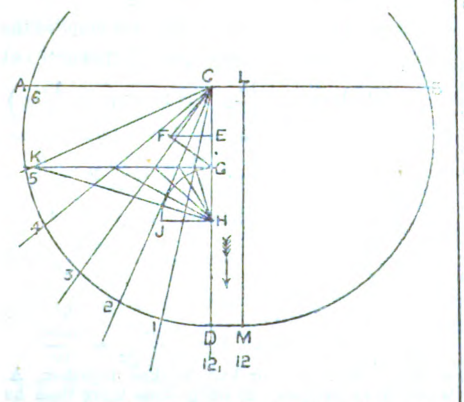
∴ the cubic inches of steam used at every stroke, the cut-off being ·21—

$$= 57905{\cdot}9712 \times {\cdot}21 = 1760 \text{ roughly.}$$

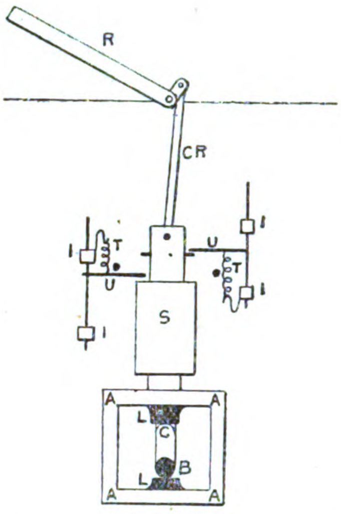
Now, to get the condensing water for this volume of steam, we must know first, as will be shown hereafter, the volume of water evaporated in the boiler to get this quantity of steam. Well, we know that one cubic inch of water evaporates 1,700 cubic inches of steam. ∴ a little more than one cubic inch of water evaporated in the boiler would give the steam in the cylinder. From Watt, we know that 28·9 cubic inches condensed water is required for one cubic inch of water evaporated in the boiler. ∴ we can safely estimate that the quantity of water, in cubic inches, to condense the number of cubic inches of steam in the cylinder will be 30. *Answer.*—A. B. C.

[56834.] — **Sundials.** — Article "Dialling," *Encyclopædia Britannica*; "Mechanick Dialling, or the New Art of Shadows," by Charles Leadbetter, London; "The Art of Dialling," &c., by Thomas Fale; "The Art of Dialling," by John Blagrave; "The Art of Dialling," by Samuel Foster, London; "Four Treatises on Dialling," by John Collins; "Universal Way of Dialling," by King.—G. Dickson.

[56834.]—**Sundials.**—To make a horizontal sundial, draw a line A B, and at right angles to same draw the line C D, and at any point E draw E F perpendicular to C D. Make the angles F C E, E F G, each equal to the latitude of the place in which it is proposed to erect the sundial. Make G H equal to F G. At the centre H, at distance H G, describe the quadrant G J, and divide same into six equal parts, and through the five points draw lines terminating in the line G K, which is parallel to A B; and then through the points in G K, where these lines terminate, draw five other lines from the point C, as shown in diagram. From E describe an arc A D, and number the points of intersection as indicated in diagram, and half the dial is complete. Let C L D M represent the hand to throw the shadow; it will have its point at C L, and the angle of which C L is the apex must be equal to F C E, and must point due south, the arrow in sketch pointing to the north. To complete the dial, measure off places from or corresponding to those on the other side, and commencing at 12 number them 11, 10, 9, 8, 7 till ariving at B, which you number 6, as on the opposite side. If you desire to divide the dial into quarters of an hour, simply divide the parts cut off in G J into four, and proceed as before. You will note that the dial is not a circle, but the second half is described from a point in L M corresponding to E.—Fred. A. Robinson.



[56839.] — **Automatic Steering Gear.**—A cam C, which works on the centre B, is connected by means of a small spindle to wheelwork underneath a brass plate, which is made to revolve once in a minute. This cam works inside a square of brass A A A A, and as it revolves therein it catches the projecting pieces L L and pushes the square up and down. A brass rod, which is connected to the square, slides through the slide S. A smaller rod is connected to this, which is fastened to a lever fixed on the rudder R. In order to bring the rudder into place again, when the cam has left the projections on square, two springs, T, one on each side of the small rod, pull it back by means of the catches V V, which slide through I I I I.—W. E. S.



[56841.]—**Accumulator.** — For practical purposes the pressure due to the height of the water in the accumulator may be neglected in this case: since it is only 1·31b. per sq. inch, it will go to compensate for loss on friction, &c. To find the weight on the column of water, including the weight of ram, of course, multiply the sectional area of ram in square inches by the required pressure per square inch: the result is the load required. The power required to drive the pumps will be equal to the area of the discharge pipe in square inches, multiplied by the velocity of the water through the pipe in feet per minute, multiplied by the pressure per square inch. This will give the power in foot-pounds per minute. The tensile stress on the sides will be equal to the internal diameter in inches multiplied by the pressure in pounds per square inch. Taking the tensile strength of cast iron at 10,500lb. per square inch, and using a safety factor of 5: thus—

$$5\,d\,p = 2\,t \times 10{,}500$$

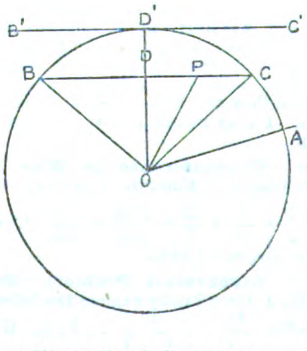
$$\text{or } t = \frac{5\,d\,p}{2 \times 10500}$$

where $d$ = internal diameter, and $p$ = pressure per square inch. This will give for 150lb. pressure—

$$t = \frac{5 \times 18 \times 150}{2 \times 10500} = \tfrac{3}{4}\text{in.}$$

—R. W., Newcastle-on-Tyne.

[56844.]—**Mathematical.**—Take O the centre of the circle, O A the initial line, B C the chord whose equation is to be found, D the centre point of B C, then we have the angle D O C = B, D O A = A, and if $\gamma$, $\theta$ are the polar co-ordinates of any point P in the line B C, $\gamma$ = O D sec. D O P = sec. $(a - \theta)$; but O D = O C cos. B = C cos. B, C being the radius of the circle; thence $\gamma = c$ cos. B sec. $(a - \theta)$. Now, suppose the chord B C to move parallel to itself until it reaches the point D′ on the circumference of the circle; it then becomes a tangent at the point D′ and the angle B O C or B vanishes; then cos. B = 1, and the equation of the tangent becomes $\gamma$ = C sec. $(a - \theta)$, where $c$ and $a$ are the polar co-ordinates of the point of contact.—H. H.



[56844.]—**Mathematical.**—Let AB (Fig. 1) be the chord subtending at the centre O an angle = 2 B. Let C O E = $a$ and radius of circle = $c$. Let P be any point on the chord, O P = $r$, the radius vector, and C O P = $\theta$—

Then O E = A O cos. A O E = $c$ cos. B,
also O E = O P cos. E O P = $r$ cos. $(\theta - a)$

$$\therefore c \cos. \text{B} = r \cos. (\theta - a)$$

$$\text{and } \therefore r = \frac{c \cos. \text{B}}{\cos. (\theta - a)} = c \cos. \text{B} \sec. (\theta - a)$$

Again, to find the polar equation to the tangent at a given point: Let Q P C (Fig. 2) be the tangent at any point P, and Q any other point on the tangent. Let C O P = $a$, and C O Q = $\theta$. Let radius vector, O Q = $r$, and radius of circle = $c$.

FIG. 1.

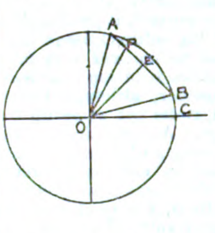


FIG. 2.

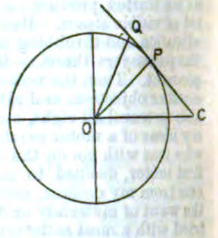
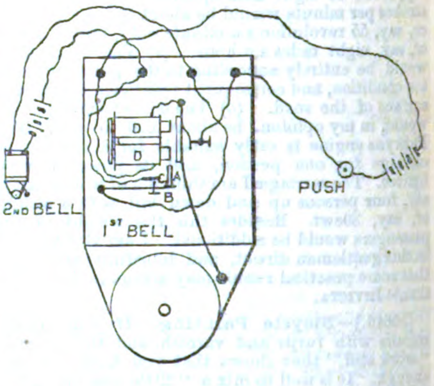


Then $c = r$ cos. Q O P,
or $c = r \cos. (\theta - a)$.

$$\therefore r = \frac{c}{\cos. (\theta - a)}$$

or $r = c \sec. (\theta - a)$, the required equation.
—J. E. Gore.

[56846.] — **Connecting Electric Bells.**—I forward rough sketch of electric bell, which I think will suit "Ignorant." Directly the circuit is completed in the first bell, the armature A is attracted by the magnets D, causing the screw B to press against the upright C; thus completing the circuit through the second bell.—W. E. S.



[56856.]—**Engine Query.**—"Goodeve" must have made a mistake in giving the data of this query; for, as it stands, it gives a gain of over 200,000ft.-lb. per minute.—R. W., Newcastle-on-Tyne.

[56856.]—**Engine Query.** — "Goodeve" must have made some mistake in the wording of his question. For, as it now stands, he can get more work out of his engine than he gives to it. This will be seen from the following calculation. The work in ft.-lb. applied to the piston = 400 × 25 × 15 × 2 × 4 = 1,200,000ft.-lb. per minute; and the work developed per minute $= \frac{400 \times 2240 \times 10}{6}$ = 1,493,333·3ft.-lb., being an excess over the work applied of nearly 500,000ft.-lb., and no power lost in the machinery. Are you right in saying that the number of double strokes made per minute is fifteen?—A. B. C.

[56857.]—**Diminished Power of Engine.**—It moves the reversing link over, bringing the slide-rod motion-block nearer to the centre of the link, thus shortening the travel of the slide-valve, and giving the ports less opening to steam. When the reversing lever is in the central position, the motion block is in the centre of the link, which will oscillate on the block, and give no motion to the slide-rod. Thus we can get any length of travel for the slide-valve up to the full travel, and consequently any degree of wire-drawing of the steam.—R. W., Newcastle-on-Tyne.—

[56858.]—**Horse-Power of Engine.**—If we take the total pressure on the piston at 50lb., then it will travel 100 × 144ft. per minute, and the horse-power will be—

$$\frac{100 \times 144 \times 50}{33,000} = 21\tfrac{8}{11}\text{h.p.}$$—R. W., Newcastle-on-Tyne.

[56858.]—**Horse-Power of Engine.**—H.-P. (horse-power) $= \frac{\text{work in ft.-lb. per min.}}{33,000}$ 1 cub.ft. of steam per minute does $144 r\, p_e$ ft.-lb. of work. Now, $r = 1 + p_e = 50$lb.

$\therefore$ 1 cub. ft. does (144 × 50 =)7,200 ft.-lb.
$\therefore$ 100 „ 720,000 ;

from which required horse-power of engine $= \frac{720}{33}$ = 22. Answer.—A. B. C.

[56862.]—**Scraping Metal Surfaces.**—Shelley's "Workshop Appliances," published by Longmans, will give you the information required; or there is a more elaborate book, of which Prof. Goodeve is the author. The latter is upon the Whitworth measuring machine, but it contains a full description of what you want.—FRED. A. ROBINSON.

[56875.]—**Thymol.**—I thank Mr. Grey for his reply; but I was not aware before that there were two varieties. I have tried the plan he suggests—viz., adding warm water to an alcoholic solution; but when it has gone cold the thymol separates out. I cannot say which variety I have used, by the nomenclature he gives, but it is in the form of a semi-transparent crystal. Caustic soda will dissolve it without separation afterwards; but would this destroy its antiseptic properties?—NOVICE.

[56878.]—**Mineral Water.**—This query is not sufficiently definite. Does "M. W." mean that he employs citric acid in the preparation of the syrups for aërated waters? If so, Goold, author of the "Aërated Waters: How to Make Them," is strongly in favour of acetic as against citric and tartaric acids; and I really do not see what objection can be urged against its use, if pure, that would not tell equally against using vinegar, and the whole tribe of sauces and relishes, at table. If, however, he is alluding to the production of $CO_2$ in bottle, the case would be somewhat different.—PERCY W. STANLEY, 119, Manchester-road, Poplar, E.

[56881.]—**Observatory Dome.**—A dome is a difficult matter to deal with in a manner that is satisfactory every way. Knowing by the experience of friends that zinc is a most unsatisfactory material, I tried my hand at making a dome with sheets of patent sheet tin. This was far better than zinc: it was easier worked, the joints were all soldered, and it was both strong and rigid. The sheets were cut to a template so as to produce the proper curve, and then were hollowed out by a wood mallet, several being worked at a time, the right curve being found by using a wood template, or rather a series on a bar. This dome, which was built some years ago, is still in use, and is in first-class condition. But the labour was too much on it. Subsequently, attempting another one, I tried an entirely different plan, taken from the huts of one of the savage tribes. In the centre was a circular plate of iron dished to the curve of the dome; to this was riveted light frames of T-iron, the lightest I could get, the web being cut away where they were riveted to the circular centre; two circular ring ribs tied these together. Over all was stretched canvas well painted in and out. The gores thus formed by the iron ribs I further reduced by the use of light rods or bars bent to the curves of the roof, the inner ends being brought into a wood centre screwed up to the iron one. The appearance is very good, and there is no nuisance such as a metal dome is sure to cause. Any particulars are freely at your service if you like the plan. The outside looks well: it is rigid, and inside the ribs give it a satisfactory look as well. The revolving top is carried on three points only, and revolves with the greatest ease.—INVICTA.

[56883.]—**Portrait Photography.**—I strongly suspect that you are labouring under a slight delusion with respect to your photos. The negatives are not over-exposed, but under-exposed. Do you get the detail all right? If not, this is certainly the case. Perhaps you don't put enough pyro solution in the developer. Try exposing them much longer and not quicker. If they were fogged you would not get sharp negatives, but there would be a kind of haze over all the objects, and no sharp definition of lights and shades. In this case you would not, very likely, get the white appearance at the back. Put your plates in the oven for a few minutes: sometimes this vastly improves them when they don't work well. Do not over-develop them: this is another mistake which would cause the misfortune you describe.—R. A. R. BENNETT, Vicarage, Frome-Selwood.

[56885.]—**Potato Cleaning.**—A simple plan would be to construct a watertight wood box; in it have a spindle, turned by handle outside. On this spindle have fixed bundles of stiff hair, or fibre, similar to a hard sweeping brush. Supposing the top to be open, put in, say, a lot of potatoes and water. By turning the handle they would be scrubbed and moved briskly about; water should be arranged to flow in and out by an overflow. A flap door with a joint made with a rubber washer and a bar would give a quick way of emptying out the wasted vegetables.—INVICTA.

[56886.]—**Model Boiler.**—Spirits burnt under any condition sufficient to raise steam quickly are certain to make some little smell. The form of lamp I should use for it would be that of a siphon form. I should make it in one of several ways. One would be a small reservoir or wick box, or furnace, 3½in. diameter, 1in. deep. In this I should fit eight wick tubes, each made from ½in. brass tube, five of them in a circle close to the edge of furnace box, the other three as an inner circle. From this box is a tube, say, ¾in. diameter, to a spirit reservoir a few inches away; and with the ¾in. tube arranged to carry a siphon wick, the feed will be steady and constant, and as little smell will result as may be. See that the air admission to the firebox past the lamp is ample, as incomplete combustion is the most fruitful source of smell possible.—INVICTA.

[56891.]—**Shocking Coil.**—If your coil gives no results whatever with a pint Bunsen connected to it, there must be a serious defect somewhere, which the addition of an extra cell would not remedy. It would be difficult to say where the defect really is, as many conditions must be fulfilled in order to produce a successful coil. You do not mention the size of the secondary wire, nor the manner in which the connections have been made. Can last week's replies to 56872 not help you?—BOBADIL.

[56895.]—**Cutting Wards of Keys.**—"Agricultor" should try a circular saw. I succeeded very well with one about 4in. in diameter, it cut through ⅛ of an inch easily.—C. L.

[56899.]—**Boiler.**—To "INVICTA."—Your boiler will drive the 2½in. by 5in. engine; but the heating surface is none too large, so that you must not expect to run at much speed. I am supposing that the boiler is a plain cylinder with egg ends; but do not carry more than 20lb. to the square inch. Much will depend on how it is fixed, as to whether its full power is got out of it. For such a small boiler I should fix it in brickwork; the fire carried as is usual with externally-fired boilers. Then carry a straight flash flue to the chimney. To feed-in the water you may use a pump on the engine, or a modification of the feeder I sent a sketch of to the "E. M." some time since. I would also strongly advise fitting a stay to this boiler—say, ⅜in. diam., with an extra deep nut and washer at each end to draw up with. I will, if you wish, give further instructions as to boiler setting and feeder suitable for your boiler, if you think it needful.—INVICTA.

[56900.]—**Cost of Locomotive.**—Eleven years ago cost of locomotive and tender did average £2,500 to £3,000; but prices have gone down, and we take the average now as £2,200 to £2,700.—MANCHESTER.

[56902.]—**Electric Lighting on Trains.**—The Chingford line trains are still lighted by the method mentioned, and have been for some time. I hear that the company are going to extend its use to the other lines. The extinction of the lamps at the termini would hardly be noticeable, as the wires are coupled to one engine as soon as they are uncoupled from the other.—FABER FABRUM ADJUVET.

[56904.]—**Problem in Algebra.**—In the expansion of $(x + a)\,4^n$, the number of terms will be $4n + 1$, and the middle term will be the $(2n + 1)$ th. Hence the co-efficient of the middle term will be

$$\frac{4n\,(4n-1)\,(4n-2)\ldots\ldots\ldots\ldots 4n-(2n+1)+2}{1\,2\,3\ldots\ldots\ldots\ldots 2n+1-1}$$
$$= \frac{4n\,(4n-1)\,(4n-2)\ldots\ldots\ldots\ldots 2n+1}{1\,2\,3\ldots\ldots\ldots\ldots\ldots\ldots 2n}$$

Multiplying this above and below by $\underline{|2n}$, we have:

$$\frac{4n\,(4n-1)\,(4n-2)\ldots\ldots\ldots\ldots\ldots 2n+1 \quad \underline{|2n}}{1\,2\,3\ldots\ldots\ldots\ldots\ldots\ldots\ldots 2n \quad \underline{|2n}}$$
$$= \frac{1\,2\,3\,4\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots 4n}{\underline{|2n}\ \underline{|2n}}$$
$$= \frac{(1\,3\,5\,7\ldots\ldots 4n-1)\,(2\,4\,6\,8\ldots\ldots\ldots\ldots 4n)}{\underline{|2n}\ \underline{|2n}}$$
$$= \frac{(1\,3\,5\,7\ldots\ldots 4n-1)\,2^{2n}\,(1\,2\,3\,4\ldots\ldots 2n)}{\underline{|2n}\ \underline{|2n}}$$
$$= \frac{2^{2n}\,(1\,3\,5\,7\ldots\ldots\ldots\ldots\ldots 4n-1)\,.\,\underline{|2n}}{\underline{|2n}\ \underline{|2n}}$$
$$= \frac{2^{2n}\,1\,3\,5\,7\ldots\ldots\ldots\ldots\ldots\ldots\ldots 4n-1}{\underline{|2n}}$$
$$= \frac{2^{2n}\,1\,3\,5\,7\ldots\ldots\ldots\ldots\ldots\ldots\ldots 4n-1}{1\,2\,3\ldots\ldots\ldots\ldots\ldots\ldots\ldots 2n}$$

—J. E. GORE.

[56904.]—**Problem in Algebra.**—I think "Bunsen" will find the following a correct solution of his question:—In expansion of $(x + a)^{4n}$, the middle term is clearly that term which contains $x^{2n}$. Expanding, we see that the coefficient of $x^{4n-r}$ is—

$$\frac{4n\,.\,(4n-1)\ldots\ldots\ldots(4n-r+1)}{\underline{|r}}$$

put $r = 2n$, and we get coefficient of middle term

$$= \frac{4n\,(4n-1)\ldots\ldots\ldots(2n+1)}{\underline{|2n}}$$
$$= \frac{4n\,(4n-1)\ldots(2n+1)\,.\,2n\,.\,(2n-1)\ldots\ldots 3\,2\,1}{[\,\underline{|2n}\,]^2}$$
$$= \frac{(4n-1)\ldots\ldots 5\,3\,1\,.\,2^{2n}\,[2n\,.\,(2n-1)\ldots\ldots 2\,1]}{(\underline{|2n})^2}$$
$$= 2^{2n}\,\frac{1\,3\,5\ldots\ldots\ldots(4n-1)}{1\,2\,3\ldots\ldots\ldots 2n}.$$

—G. F. P.

[56904.]—**Problem in Algebra.**—$(x + a)^{4n} = x^{4n} + 4n\,x^{4n-1}\,a + \frac{4n\,\overline{4n-1|}}{1\,.\,2}\,x^{4n-2}\,a^2$

The coefficient of the middle term is—

$$\frac{4n\ \overline{4n-1|}\ \overline{4n-2|}\ \ldots\ldots\ldots\ \overline{4n-2n+1|}}{1\,2\,3\,4\ \ldots\ldots\ldots\ 2n}$$
$$= \frac{4n\,(4n-1)\ldots\ldots\ldots 3\,2\,1}{(1\,2\,3\,4\ldots\ldots\ldots 2n)^2}$$
$$= 2^{2n}\,\frac{2n\,(4n-1)\,(2n-1)\,(4n-3)\ldots\ldots 2\,3\,1\,1}{(1\,2\,3\,4\ldots\ldots\ldots 2n)^2}$$
$$= 2^{2n}\,\frac{1\,3\,5\ldots\ldots\ldots(4n-1)}{1\,3\,3\,4\ldots\ldots\ldots 2n}$$

—C. P. W.

[56907.]—**Electro-Magnetism.**—How to produce a cheap supply of electricity to feed an electro-magnet lifting from one to two tons, is a problem which has yet to be solved. Electro-magnets of great power can be easily constructed, and a supply of current to work them can also be guaranteed; but the economy of the business is another question. The simplest source of supply would, of course, be the battery; but meaning, as it does, the dissolving of zinc in acid, it would be a most expensive one. Leaving out altogether the cost of the acid, the zinc, which is the very fuel of the battery, costs more than 20 times as much as coal, besides being a far worse fuel.—BOBADIL.

[56908.]—**Caloric Engine.**—I could not help you unless I had far more particulars, and also I should want to see a general sketch to enable me to put you right at once. If you like to advertise your address, I would communicate, and assist you to a successful issue. The loss of power due to the pump may be much or little, just as the arrangement is for feeding it in. Asbestos is not, as a rule, a good packing at all for glands or parts in motion. But I can show "Romeo" how to get over that. Hot-air engines are not so successful as they should be, and, at the best, are not up to a steam-engine, as a rule. The feed, instead of being as, say, 1 to 470, is something like to 1 to 3 only, so that the margin is but small.—INVICTA.

[56910.]—**Flame.**—The reason why the carbon in a luminous flame is not all consumed, but becomes luminous, is that there is not a sufficient supply of oxygen to combine with it. But in the Bunsen, or atmospheric burner, an additional amount is supplied through the air-holes, and the carbon is therefore consumed.—FABER FABRUM ADJUVET.

[56910.]—**Flame.**—The explanation of the Bunsen burner is that the air mixes with the gas as it ascends the tube through the holes at the bottom. As the air contains oxygen, the carbon, which would naturally be in a state of incandescence, is all burnt up instead. The following takes place: the C now having enough O to combine with: $C + O_2 = CO_2$. All luminous flames contain particles of unburnt carbon except that of $CS_2$ in nitric oxide, in which there are no particles, though it is a luminous flame.—R. A. R. BENNETT, Vicarage, Frome.

[56910.]—**Flame.**—The action of an atmospheric gas burner is to burn up the carbon of the gas quicker than in an ordinary burner. In both cases water ($OH_2$) and carbon ($CO_2$) are formed, but in the latter case (i.e., ordinary burner) the carbon, by means of the heat given out by combustion of the hydrogen, is first raised to a white heat and then consumed; whereas, with the Bunsen burner, there being such a great supply of oxygen, the carbon is consumed before it can become incandescent.—A. B. C.

[56911.]—**Writing on Glass.**—Grind lampblack with gumwater and some common salt, draw the design with a pen or hair pencil, or use a crayon made for the purpose.—C. L.

[56911.]—**Writing on Glass.**—You could do it with a strong solution of hydrofluosilicic acid and a quill pen. Mind your fingers.—R. A. R. BENNETT, Vicarage, Frome.

[56917.]—**Plaster Ceiling Centres.**—Plaster centres are run into moulds made of plaster or gelatine (glue), according as the pattern is plain or intricate. If he will advertise his address in the sale column, I can refer him to a firm doing splendid work.—BARIUM.

[56918.]—**Gas Engine.**—The most economical dimensions for a two-man non-compressing engine cylinder would be 5in. bore and 12½in. stroke, assuming that it was run at about the speed of the Bischopp. The flywheel question is more complex, and I should want to know if your proposed engine was to be with the piston below the crankshaft of the horizontal type, or with the cylinder above the crank. I will, on hearing from you, give size and weight suitable.—INVICTA.

[56921.]—**Heat for Workshop.**—Just a problem I have long tried to solve for myself. The nearest approach to it was a plan I tried of a cast-iron tray or stand on feet to hold coke, broken small; at the back was a spirit lamp, the large brush flame from which was directed, with the aid of an air blast, on to the coke. In two or three minutes I had a little fire capable of heating small tools, or drills, &c.; whilst for brazing it was very handy, although it burnt a lot of spirit. I also had a somewhat better plan of using with the same forge arrangement, and using the meth. spirit in the form of spray with the air blast. It certainly was better, and after the coke was incandescent the spirit was shut off and the air blast alone used. Would this suit you?—INVICTA.

[56925.]—**Draught in Chimney.**—I have heard persons say the same; but, in my opinion, the matter is a ridiculous fallacy. The reducing the area of the chimney would, in very rare instances, increase the draught when the chimney was largely in excess of the grate area; but such cases are very rare, and I would advise you to look for and remedy the matter at the point where the cause really is. Now, as I have not seen the boiler, or in default of any other data, my opinion would be that the setting of boiler was in fault, or that part of the flue area was choked up. If your boiler was a tubular one, then the circumstance would be otherwise; but from the grate surface I should presume it was not. Either there is an obstruction in the flues, the flues are badly built, or the products of combustion are cooled so much that the ascensional power is insufficient.—INVICTA.

[56928.]—**Re-silvering Mirrors.**—It is not worth the trouble, nor can you do them as cheaply as you should be able to get them done—I mean making up solutions and other matters that will cost you far more than it is worth. You would need quite a small collection of apparatus as well. A far simpler way, but one equally needing patience, is the silvering with mercury and tinfoil.—INVICTA.

[56931.]—**Bearing Grease.**—I cannot say anything about the "twopence a pound," because obviously the cost of the grease will depend on the prices paid for the raw materials. I give two recipes, because "bearing" grease is not exactly a definite term. Tallow, 8lb.; palm oil, 1 gallon; mineral oil, 1 gallon; plumbago, 1lb. Melt with heat in a vessel in the open air (to avoid fire) and mix thoroughly. A commoner grease is made by dissolving half a pound of soda in a gallon of water, to which add 4lb. of tallow, 6lb. of palm oil, and a gallon of mineral oil. Melt as before and mix thoroughly.—ESSAR.

[56932.]—**To "M. I. C. E."**—Thanks to "A. S. L." for introducing me to a very interesting problem. Geometrical problems, involving the use of the integral calculus give such neat results that it is quite a pleasure to work them. If we draw a circle to represent the section of the sphere through the centre, then draw horizontal and vertical diameters for the axes of $x$ and $y$, and two parallel lines equidistant from the axis of $x$ to represent the boundaries of the hole bored through the sphere, we have our figure complete, the axis of the hole being thus the axis of $x$. Call the radius of the sphere $a$, and the radius of the hole $r$. The hole may be considered a cylinder with flat ends, with segments of the sphere added to each end. The volume of the former will be $2\pi r_2 \sqrt{a^2 - r^2}$; and for the segmental ends We must have recourse to the integral calculus. Suppose the circle to revolve round the axis of $x$, the volume of the solid so generated will be represented by $\int \pi y^2 \cdot dx$ taken within certain limits. Now, the equation to the circle, the origin being at the centre, is $y^2 = a^2 - x^2$. Substitute this value of $y^2$ in the above expression and integrate, and it will then become $\pi\left(a^2 x - \frac{x^3}{3}\right)$. Now, as we only require the segments at the ends of the hole, the limits between which one of these segments lies will be (measuring along the axis of $x$), $\sqrt{a^2 - r^2}$ and the radius of the circle or $a$. Substitute first one and then the other of these limits for $x$ in the last expression, and deduct one from the other, and we will then have an expression for the volume of one of the segments. Multiply this by two, and add to the volume of cylindrical hole given above, and we thus obtain an expression for the volume of the substance bored out. This, by the conditions of the problem, is to be equal to half the contents of the sphere, or $\frac{2\pi a^3}{3}$. The equation is too long to print; but from it we find that—

$$r = \frac{\sqrt{2^{\frac{2}{3}} - 1}}{2^{\frac{1}{3}}} a$$

As $a$ is 6in., $r$ will be found to be 3·648, nearly. Now, as regards the coincidence mentioned. The side of the pentagon will be $2a$ sin. 36°, and the arc will be $\frac{2\pi r}{5}$, add these, and divide by two to get the arithmetical mean; this result should be equal to twice the value of $r$ given above, if it were not a mere coincidence. Let us see whether this equation will hold. Solve it for $\pi$, and we find that $\pi$ will come out = 3·144, instead of, as it ought to be, 3·1416, showing that it is a mere approximation; besides, sin. 36° can be expressed in terms of various roots of certain numbers, so we get $\pi$ equal to an exact expression involving various square and cube roots, whereas $\pi$ is only capable of being expressed by an infinite series, at least, so I believe. The second part of the query contains an interesting statement; I have tested it, and find it quite correct.—M.I.C.E., Bath.

[56933.]—**Mechanical.**—The dioramic change is produced by painting on the back of the front scene with transparent colours. Gas lights are placed so that when those in front are turned down, those behind are turned up. I would, however, wish to strongly advise you not to arrange your scenes to wind up window-blind fashion. I have seen at least one good diorama entirely spoilt by this plan.—INVICTA.

[56933.]—**Mechanical.**—A beautiful theatrical effect I have seen of a winter scene changed instantly into a summer landscape by the appropriate tints being flashed upon it by a powerful magic lantern. To change a day effect into a night scene I would paint on semi-transparent cloth, and illuminate from the front for day and from the back for night. Buildings and solid objects being painted solidly to be opaque to the latter, the moon and coloured lights being arranged behind in the necessary positions, by graduating the opacity of the painting of clouds and distances pretty effects could be introduced.—HAMMER.

**Bengal Lights.**—It is well known that the compositions of the coloured Bengal lights are dangerous on account of their spontaneous inflammability, and it is well therefore to publish here the results of Thoerner's investigations on this subject. According to Thoerner, only perfectly pure chemicals should be employed, especially when potassium chlorate is one of the constituents. Friction, shock, and heating increase the danger. The point of inflammation generally changes by and becomes lower, so that the danger increases with age. The addition of lycopodium does not in any way diminish the danger, as has been stated by some. *White.*—Potassium nitrate 24, washed flowers of sulphur 7, arsenious sulphide 2. II. Potassium nitrate 4, flowers of sulphur 2, antimonious sulphide 1. III. Potassium nitrate 16, sublimed sulphur 8, flour 3. IV. Potassium nitrate 36, sublimed sulphur 7, antimony 12. V. Potassium nitrate 8, antimonious sulphide 1·5, washed flowers of sulphur 2·5. VI. Potassium nitrate 12, washed flowers of sulphur 3, antimony 2. *White* (theatre fire, poured out loose).—I. Potassium nitrate 72, sublimed sulphur 12, antimonious sulphide 12, arsenic disulphide 8, shellac 1. II. Potassium nitrate 32, sublimed sulphur 8, antimonious sulphide 12, red lead 11. *Yellow.*—I. Sodium nitrate 24, arsenious sulphide 2, sulphur 7, antimony (crude) 2. II. Potassium nitrate 16, sulphur 4, flour 16, amber 4, pine resin 3, pitch 4. III. Sodium nitrate 6, sulphur 1, soot 1. *Blue.*—I. Potassium nitrate 16, antimony (crude) 8, zinc 7. II. Ammoniacal copper sulphate 2, potassium chlorate 4, sulphur 1. III. Potassium chlorate 3, mountain blue 1, sulphur 1. *Violet.*—Potassium chlorate 49, sulphur 25, precipitated calcium carbonate 20, black oxide of copper 6. *Red.*—I. Potassium chlorate 5, strontium nitrate 16, arsenious sulphide 1, sulphur 2, soot 1. II. Potassium nitrate 5, sulphur 2, antimony (Regul.) 1. III. Strontium nitrate 20, potassium chlorate 2, sulphur 5, antimony (crude) 0·5, charcoal 2. IV. Strontium nitrate 48, flowers of sulphur (washed) 9, pulverised charcoal 2, potassium chlorate 8. V. Strontium nitrate 5, washed flowers of sulphur 15, charcoal 0·5, potassium chlorate 0·5.

AN experiment was made recently in Birmingham with a new fire-escape, manufactured by the Birmingham Fire Brigade, from the design of the superintendent, Mr. Tozer. The escape is in the form of a canvas "shoot," but, unlike all others, it is inclosed to within 10ft. of the ground. It can be firmly fixed inside the window in a few seconds.

# UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

# QUERIES.

[56935.]—**Choke Damp.**—What is this?—LEVER.

[56936.]—**Patent Law.**—Does the amount for bringing out a patent vary according to the invention, or under the 1884 Act, is it a uniform rate?—LEVER.

[56937.]—**Tons Measurement.**—What is meant by tons measurement of a ship?—LEVER.

[53938.]—**Electro-Magnet.**—Would some kind friend be so good as to throw some light on the following? I am wishing to fix an electro-magnet (1in. core horse-shoe) on to a spindle of brass, ½in. diameter, the leg being parallel to the spindle. Would it affect the hold-power of magnets, if the hole were bored through centre of magnet, or would it be better to make spindle of steel, and make magnet thicker at that point? An answer will greatly oblige.—A SCEPTIC.

[56939.]—**Armature.**—I was thinking of constructing a small model of a Siemens dynamo, but was at a loss about what armature to use. I do not understand a Siemens armature. Could one of our electrical readers tell me if a laminated armature with four sections of wire would suit? An answer would obliged.—ACCUMULATOR.

[56940.]—**Am-meter.**—Could one of our electrical readers give me a sketch and description of a simple but effective am-meter, indicating up to about 10 ampères? An early answer will oblige.—ACCUMULATOR.

[56941.]—**Novel Clock.**—To "GARRISON GUNNER."—I intend making for my own use, one of your novel clocks, from your description (letter 24327); but would like to ask whether I could substitute a brass bowl instead of china? If not, would an ordinary white pudding basin do, with a stand to it, or must it be flat-bottomed?—A. H.

[56942.]—**Electro-Magnet.**—I took a piece of soft iron about 6in. long, and ½in. thick, and heated it in smithy fire, then bent it into magnet shape, and allowed it to cool by itself, afterwards rounding and polishing it, and planing poles with a file. I then took some small pitch-covered wire, the same as is used for telephones inside, and wound it in a right-handed helix, about six times round each leg, having previously covered them with cloth. I also tried it without the cloth, and with cloth and wire naked. I connected the wire to an electrical machine that is used for personal application, by fastening each end, immediately above the handles of the machine. I allowed these to remain, properly isolating them of course. On no occasion could I get as much magnetism as would lift an ordinary sewing needle, even with the machine going at high rate of speed. The machine is in excellent condition. Is the electric bell not rung by a similar machine? What is the matter?—D. W.

[56943.]—**Engineer's Book-Keeping.**—Being prime-cost clerk in a large engineering firm, will someone be good enough to inform me as to whether there is any standard of profit for time, and material for (1) new work, and (2) repair jobs;—class of work, soda-water machinery.—JOHN WHITE.

[56944.]—**Solubility of Carbonic Acid.**—Would some of our chemical readers kindly state the solubility of carbonic acid, in different strengths of hydrochloric acid?—LYNTON.

[56945.]—**Clarionetta, Oboetta, or Bassoonetta.**—Will any musical friend say if the above, in form of an ordinary keyboard, played as harmonium, are as powerful, and exactly the same tone as the instruments they are intended to represent, and where they can be obtained?—CONDUCTOR.

[56946.]—**Clock Springs.**—Can any of our readers inform me what is the strongest spring I can get the same as clock springs?—L. BALDWIN.

[56947.]—**Rotary Hair Brush.**—I am about to make a rotary hair brush. What description (and about what cost) of bristles to be used?—A. J. B.

[56948.]—**Gas Producing Apparatus.**—Will some kind correspondent to the "E. M." inform me how to make a gaseline gas generator, for a small gas engine, or is there any oil-gas apparatus that could be fitted up as cheaply, producing as good or better gas? Any information on the above that will help an amateur, will be thankfully received by—GASEOUS.

[56949.]—**Manufacture of Aluminium.**—Will any of our chemical correspondents, kindly say in a few words, what process is now used for making aluminium? Is sodium still used in the manufacture, and from what compound of aluminium is the metal obtained?—EX-GARRISON GUNNER.

[56950.]—**Hat Lining.**—I have a hat, the leather lining of which stains my forehead a brilliant yellow, especially when I get warm. The hat is of good quality, and cost a good price. Can anyone tell me how I can prevent the stain coming off, by doing something to the leather?—SAFFRON.

[56951.]—**Dynamo.**—To MR. BOTTONE OR "W. H. E." —I have a dynamo, of which the following are particulars:—Upright field-magnets, cores for winding are, each, 8½in. by 4½in. by 1in.; pole pieces are 6½in. by 3in. by 3in.; and each covers ⅓ the circle of armature. The armature is an iron drum, 6in. long, by 2½in. diameter and the metal is ½in. thick. The curve in magnet poles, is 3in. diameter, so there is ½in. space between armature drum and magnets for wire. I purpose winding it similar to Siemens armature, that is longitudinal coils, enveloping the drum, and connected to a number of segments on commutator. Will you please tell me the number of segments, size of wire, or how many fine wires in parallel will best suit the armature for low resistance, as I have decided to make it a shunt machine? Also what size wire for the magnets, of which I think I can get 12lb. on each limb? I should like the E.M.F. to reach 20 volts.—CARNFORTH.

[56952.]—**To "F. R. A. S."**—Will "F. R. A. S." kindly give the variation at the present time, of the magnetic meridian, from true north at a place in East Yorkshire, latitude, 53° 55′ 58″ N.; longitude, 0° 21′ 17″, West? Also the variation at the same place four years ago.—STREETGATE.

[56953.]—**Boracic Acid.**—What would be the best proportion to use to prevent jam fermenting?—LYNTON.

[56954.]—**Boiler Query.**—Will any kind reader inform me what thickness of brass or copper sheet is required for a model steam boiler 12in. long, 6in. diameter, riveted to stand a working pressure of 80lb. per square inch? The boiler to be horizontal, with a fire-box oval, 6in. through by 5in. wide, by 4in. deep; and what thickness of metal for firebox? There will be tubes continued to the end. Is the pressure equal all over the boiler?—A.

[56955.]—**Photography.**—I possess one of the Lancaster's Merveilleux ¼ photo apparatus, and I shall be glad if any kind reader will assist me by answering the following questions? 1st, Can I take negatives from a wet plate with it as well as the dry plate?—if so, please say what are the chemicals used for it, and how they are used? The reason I ask this is, because I find the dry plates take so long to develop and fix, and the negatives do not show up so nice as those the street photographers do, as they get them out in a short time, and can be seen much clearer. I presume good copies can be taken from them.—A.

[56956.]—**Steam**—The pressure of steam in a boiler is 60lb. by the gauge? What will be the sensible temperature and the relative volume? Show how you get the temperature from pressure. A locomotive with coupled driving wheels 5ft. diameter and two cylinders, 17in. diameter by 20in. stroke, is worked at a pressure of 120lb. per square inch; how many tons could be drawn by it on a level road at 25 miles per hour?—FRED A. ROBINSON.

[56957.]—**Ball Bearings.**—A slight accident to my tricycle, occurring a few days since, obliged me to take off and open the bearings, made by one of the leading firms in this country, when I was very much surprised to find one of the balls completely crushed to small bits, and the remainder worn down to half-size. A friend, who is a skilled mechanic, told me that the balls, which had been in use for two years, were not steel as generally supposed, but only good quality iron well case-hardened. We easily filed them upon trial. I write this in the interest of all cyclists, and shall be glad to see a reply from someone who is not a manufacturer. I am simply stating facts when I say that all the builders of bicycles and tricycles say that all balls are best cast steel.—SECUNDUS HAUD ULLI.

[56958.]—**Microscopical.**—I have an eye of a beetle prepared to show multiplied images. What power must I use, and how arrange the microscope and apparatus, to show these multiplied images? At present I can only see the hexagonal facets of any particular—EYE.

[56959.]—**Castings.**—Having had serious trouble with our castings, I should be glad if any of your readers could suggest the cause. Most of our work is light, and has to be turned and shaped all over; consequently, if not clean, has to be thrown away. When the castings leave the trimming shop they show marks like dirt or small coke (mostly in the top of the casting) which, when turned or shaped, go into small holes about the size of peas. If any of your readers could suggest a cause no doubt a cure could be found.—FOUNDRY.

[56960.]—**Riparian Rights.**—I have a boat 12ft. long, which I wish to use on the river Ouse (which is not a navigable river). Owing to disturbances by people who fish, and threats of prosecution for trespass, I wrote to Earl Spencer, who owns land on one bank, and the reply from his secretary was that I might go—he could see no objection; but about a week after, I received another letter to say that as one of the tenants objected to boats on the river, he must say no. Now what I wish to know is, can I be legally stopped from boating, if I keep in the middle of the river, and only land where I have leave so to do? Your kind advice in this matter will greatly oblige—O. J. R.

[56961.]—**Boating.**—In the experience of our readers, has anyone seen any invention or contrivance for propelling a small boat, either by paddle wheels or screw, in a similar manner to the tricycle, either by feet or hands? I have a good deal of travelling along a small river, and it seems strange to me that some mechanical arrangement cannot be contrived and attached to a small boat capable of carrying say one or not more than two persons, and by which they could travel easier and quicker than walking or rowing, and without the bother or waste of time as in a steam yacht. It would, of course, be no use unless one person could manage it, and unless it was much quicker and easier than walking or rowing. Perhaps some of our readers could assist me.—AQUA.

[56962.]—**Legal Telephone Query.**—A person, A., possesses a telephone with transmitters all complete, connected between his works and office, but at the present time out of repair. Can a person, B., a working electrician, supply the man with wire, cells, or anything that may be required to place same in working order without infringing on any patent? When A. had the instruments fixed by a telephone company, he purchased the same, and paid the Royalty, so that they would be his own—he bought straight off. Having done so, he has to repair them at his own cost. An early answer will greatly oblige two old readers of this journal. —TELEPHONE JACK.

[56963.]—**Engine Flywheel.**—To "J. H."—I shall be much obliged if you will give me dimensions of flywheel for a horizontal engine, cylinder 4in., stroke 5in., designed to run about 250 revs. per minute, pressure in boiler 79lb., steam ports 2in. by 5-16in., diameter of crankshaft 1¼in.?—R. N.

[56964.]—**Steam Blowing Engine.**—Will some kind reader of the "E M." favour me with a description of a steam-engine as used for blowing air in the Weldon manganese mud process? Also, what is the advantage of having one which condenses her exhaust steam, as against one whose exhaust escapes, and which is the best book to purchase for information about steam engines, pumps, &c., and oblige a—CHEMIST.

[56965.]—**Blasting Powder.** — Will any correspondent kindly tell me what the explosive force of blasting powder, such as is used in coal and other mines, is equal to? Say what pressure per square inch per ounce (or any given weight of powder), is exerted at the moment of explosion?—ENQUIRER.

[56966.]—**Australia.**—Will someone who has been to Australia by the Cape at this time of year, kindly inform what I had better take in the way of outfit, for the voyage, there and back in a sailing ship? I have been told regatta shirts are the best shirts, what should they be made of? Are duc (canvas) suits worn by passengers? Any advice will be thankfully received. Please mention idea of quantity.—A SICK MECHANIC.

[56967.]—**Deafness.**—Will any medical reader of the "E. M." kindly give me his advice on the following case? A polypus has been in my right ear for ten years, and was extracted about seven years ago, by a local doctor. Since then it has not materially improved, and I cannot hear with it half so well as the other, although I hear a great deal better with it sometimes, when the wax dries a little. There is a slight discharge of humour coming from it now, especially when I catch cold. I have been with two doctors to examine it, and they say there is a small hole in the drum. I have heard of false or artificial drums, will one of these do me any good?—if so, shall be glad to know what they cost, and if it is necessary to undergo an operation to fit it in? I shall be glad if any one using it, will give his experience of it. My age is 26 years. I shall feel deeply obliged to any who will give advice on the query.—IOLO.

[56968.] — **Chlorophyll.** — How is chlorophyll extracted from vegetable substances? What is its chemical composition? Has it ever been produced synthetically? The names of any treatises or books bearing on the subject will much oblige.—BOTANIST.

[56969.]—**Hydraulic Ram.**—I have one of these machines, through which a large quantity of water is supposed to pass, and a small quantity of the same water to be forced to a considerable height. It has two large valves, whose normal position is open. I understand the principle of the action to be, that when a quantity of water from a given head is passed through the machine, the sudden closing of these valves causes a momentary excessive pressure in the machine, due to the momentum of the falling inlet water, and that this is utilized to force a small quantity of the water up a pipe to a considerable height. What I want to know is, why these two large valves do not remain permanently closed after the first rush of water? In the machine I have, there is nothing but the weight of the valve itself that tends to reopen it when once closed, and I cannot see that if the valve be light enough to be overcome by a small head of water, it will not be too light to reopen automatically under a larger head. If any correspondent who is better acquainted with these things than I am, will kindly enlighten me, I shall feel much obliged. I know the general principles of the machine, but want to know if the weight of the valve must vary according to the head of water at which it is required to work.—A MELTING MECHANIC.

[56970.]—**To Mr. Bottone.**—I am making a small dynamo from castings, which I was told by maker were 30 candle-power. It has 5lb of 22 wire on F.M., and ½lb. on laminated armature. Will you tell the required speed to drive it, to obtain its full power? Also would the current be dangerous if it was sent through human body? What is the number of volts it is likely to work at?—P. E. YATES.

[56971.]—**Insects in Telescope.**—Can any one of the numerous readers of the "E. M." recommend a remedy to prevent earwigs and other insects—but especially earwigs—from getting into the clockwork, and other parts of an equatorial refractor, mounted on an iron pillar stand? Felt saturated with crude carbolic acid, and placed round the foot of pedestal, has been recommended, but its staining qualities and odour render it very objectionable. Keating's insect powder has been tried, but it seems to have no effect on earwigs.—L. M.

[56972.]—**Watchwork.**—Seeing in last week's "E. M." that "C. A. W." kindly offers to give information in the way of watch jobbing and finishing, perhaps he would be so good as to help me a little in the matter of steel polishing. Tho' I have been six years in the trade, I have never been able to run against anyone who could do this properly or tell me how. What I want is an exceedingly high polish, such as one sees in the good old work. I am not a very old reader of the "E. M.," but have never seen anything on this subject. If "C. A. W." will kindly step in, he will, I believe, oblige a good number of readers, and certainly—ESCAPEMENT.

[56973.]—**Dynamo.**—To MR. BOTTONE OR "W. H. E." —I have made a dynamo same as described by you in 1007, only in a smaller size. The F.M.s are 16in. high over all, the pole pieces being 8in. high, and the arms 8in. high; the arms are wrought iron 1⅞in. thick, and the pole pieces are of cast iron 8in. high by 3in. wide. The armature is made the same as that described by F. Walker in a back number, being composed of 80 pieces of soft sheet iron and wound with 2¼lb. of number 18cc. wire, in four sections, 10oz. of wire in four layers on each arm, and the fields are wound with 10lb. of 16cc. wire. Will you kindly say what the lighting power will be, and at what speed to drive it at, and what the E.M.F. will be in volts, and its resistance in ohms, and how many ampères of current it will give? How many 20 c.p. lamps it will light well, and what resistance the lamps are to be?—ELECTRIC JOE.

[56974.]—**Boiler.**—To "INVICTA."—I have made a boiler to drive an engine, the cylinder of which is 2in. bore and 3½in. stroke; the boiler is made of ¼in. sheet copper, single riveted, with one 3½in. flue in the centre; the height of it is 3ft. and the diameter is 14in., firebox 1ft. high. Will you kindly say if it is a suitable size, and what is the safe working pressure, and if it will want staying. I want it to drive a dynamo with; the one that I have described in this week's "E.M." Any advice will be thankfully received by—ELECTRIC JOE.

[56975.] — **Mineral Springs in and near London.**—Can any correspondent give me any information respecting these? One reads of Beulah Spa, Norwood, Kensington, Bagnigge Wells, Epsom, &c., and I wish to learn whether they still exist, and if so, where they are still to be found? The character of the water, whether saline, alkaline or chalybeate, could also perhaps be mentioned.—A. S. L.

[56976.]—**Water Meter.**—We have a water meter where I work—it is Kennedy's patent, and when there is no water using the meter knocks about every fifteen minutes, so there must be some leakage in the pipes. Could anyone say how many gallons goes every knock? The meter reads from ten millions to thousands. Also, the best method of finding the leakage, or whether it is worth seeking? I cannot find the size of the meter, but the feed pipe is 4in. outside diameter cast-iron pipe, so that it will be 3in. at least. I hope someone will oblige —ANXIOUS.

[56977.]—**Load on Short Span.**—(1) To carry a load on the centre of a short span, the following three forms of beams are proposed:—1. A bar 4in. deep and 2in. wide. 2. A bar 3·8in. diameter. 3. A bar 3·5in. square. Which is the strongest of these, and what are the relative strengths of the three? Would some reader help me with this question?—A. B.

[56978.]—**Engine Query.**—A slide-valve has to cut off steam at ⅝ of stroke, and its opening for steam is to be 1¼in., the lead of the valve is to be ⅛in. Find the stroke of the valve, and the angular advance of the eccentric? You may neglect the obliquity of the connecting rod, but state in general terms what its effect would be.—A. B.

[56979.]—**Model Locomotive.**—1. Can a boiler of the following dimensions be relied on to drive an engine with a pair of cylinders ⅜in. diameter by 1¼in. stroke? Length of barrel, 6in.; diameter of barrel 2⅞in. Length with firebox 9in.; crown of firebox, 2½in. by 2⅜in., one flue 1in. diameter, heating surface about 45in. 2. I should be much obliged by information as to the proper size of steam ports.—F. M. C.

[56980.]—**Electrical.**—I have made an iron bar upon which is mounted an iron core; upon the core is a bobbin of wire which does not quite touch the base. Upon passing a current of electricity through the bobbin it is pulled right on to the core till it touches the base. Not being acquainted with matters, perhaps some kind reader can explain this and oblige—GLONOINE.

[56981.]—**Preparing and Mounting Small Skeletons.**—I wish to know if any reader of the "E M." could give any information on the above subject? I have seen it stated that ants are very useful in removing the flesh, but living in town I cannot avail myself of their services. If any reader could recommend any preparation to remove the flesh, without injuring the bones, and give any information as to whether they require anything to preserve them, and make them white, and a few hints on mounting them—how the bones are held together, &c.—it would greatly oblige—G. H. CORBETT.

[56982.]—**Ball-Room Floor.**—The opinions of readers are asked as to the best material, and best way of laying a ball-room floor. It is required to be first-rate in every way. Is an oak floor, well waxed, better than a pine floor, grooved and tongued, and planed smooth? Would strips of rubber laid on the joists as a bed for the floorboards be an advantage, if elasticity is considered a desideratum, or would a solid, well-waxed, hard wood floor be better, considering that it is to last? Can any reader give examples of really good floors that can be seen in London?—TERPSICHORE.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

## ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

### BACK NUMBERS.

We receive so many queries asking for directions how to make many instruments and appliances which have been fully described in back volumes that we have compiled a list, which we shall insert in this column at intervals, of those most frequently sent, and as the numbers are still in stock, new subscribers should consult the list before sending their questions.

Batteries: Nos. 741.
Bookbinding: Nos. 613.
Copying processes: Nos. 750, 753.
Electric machines: Nos. 628, 759, 840.
Electro-magnets: Nos. 756, 772.
Lacquers: No. 866.
Pattern Making: Nos, 938, 941, 943, 945, 948, 950, 952, 954, 955, 956, 958, 959, 962, 963, 965, 969, 973, 974, 978, 981, 986, 989, 993, 995, 998, 1,000, 1,001, 1,003 1,004, 1,008, 1,009, 1,010.
Silver-plating: No. 880.
Telephones: Nos. 695, 747, 865.
Varnishes: 478, 619, 675, 691, 723, 775.

The following are the initials, &c., of letters to hand up to Wednesday evening, July 1st, and unacknowledged elsewhere:—

J. Place.—Jabez Francis.—J. B. Brown.—W. I. Chadwick.—J. Devey and Co.—N. G. Wilcocks.—H. Trick.—E. E. Brown.—C. Birchall.—J. Pickles.—G. Crowsley.—J. Hagger.—Clyde.—R. S. Culley.—W. C. Crick.—W. H. P.—J. C. G.—E. C. J.—An F. R. A. S.—Young Firer.—W. S. Franks.—R. F. S.—T. J. Murday.—Bacchus.—Telephone.—J. Myles.—Carbonado.—Libra.—One in the Wilds of Wales.—Experience.—K. J. Tarrant.—S. R. Elson.—F. M. Rogers.

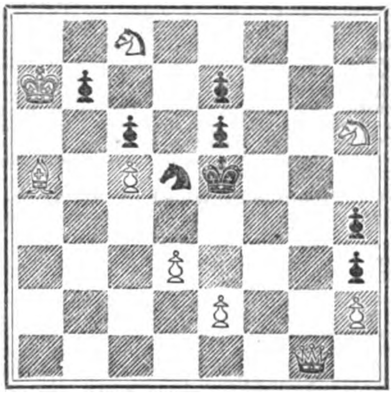
Asterisk. (It is a very useful work, because it is the only book devoted to the subject. 2. There are none which deal with the practical details of the larger machines; but there is "The Dynamo," by S. R. Bottone, which gives full directions for making a small machine. It appeared in Vols. XXXVII.—XXXIX.)—Amateur. (Yes. Try the dealers in hives.)—Novice. (Clean it off with glasspaper, and paint.)—Locomotive. (It has been described many times—so recently even as p. 292.)—Rustic. (Probably to carry a photographic camera. We presume it is a refractor, not "reflector.")—Longworth, Manchester. (You mean the foot-warmers, we presume—metal cases filled with hot water, or, on the L. and N.W., with acetate of soda, which is liquefied by heat, and as it slowly cools and re-crystallises, gives out the heat it has absorbed.)—J. R. (See the indices of many back volumes for references to a variety of flying machines. Make a calculation as to the power required to lift the weight, and then endeavour to ascertain whether a man can exert it; that is where the defect lies.)—Aeronaut. (See previous reply.)—A. B. C. (It would be simply like putting them into a close-fitting swell-box.)—Photo-lithography. (See indices.)—G. M. Callender, New York. (Thanks for the paper.)—Roi ne Puis, Souza je Suis. (Many thanks. You will have seen that we reproduced it in the number for June 19.)—W. Griffiths. (If received, it has been attended to. See Hints No. 5. We really cannot undertake to explain privately why anything is not inserted.)—John Liston. (The arrangement will do, but it is better to drive the wheel direct without the intervention of gear—that is, drive by a belt on the wheel shaft.)—Autograph. (You must employ an engraver to make the woodcut of signature.)—Limp Collar. (See p. 445, Vol. XXV. Use four ounces of common wax to about two pounds of starch, dissolving the wax in boiling water, and adding the starch which has been previously rubbed down in cold water. Starch the linen twice, drying between.)—Musician. (Glue or paste. 2. Glair—that is, white of egg beaten to a froth and allowed to stand.)—B. Jacobs. (See the indices, where you will find references to several diagrams and illustrations showing the connections and the arrangement of the parts.)—G. R. (The secret is in the "out of breath." Take time, and don't get out of breath. See pp. 5, 34, Vol. XXXVII.)—A New Reader. (Hawkins' "Treatise on the Teeth of Wheels" is a useful work.)—H. O. C. (Lac is a resin which exudes from several trees when they are punctured by the lac insect. The "shell" distinguishes it from stick-lac and seed-lac.)—Carino. (We know nothing of the Association, and hardly advise you to trust them with the P.O.O. You might send one payable ten days after date, and stop payment if it turns out wrong.)—Samuel Haigh. (For the present, as you will have seen, we have had enough about the matter. If, after you have made your experiments, you care to embody the results in a letter, we will insert it. We should be glad of the description of the incubator.)—T. C. Clarke. (Both are good at the respective prices—if anything, the first-named is the cheaper.)

## CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

### PROBLEM DCCCCXLVI.—Ideen.

*Black.*



*White.* [9+8

White to play and mate in three moves.

Solution to 943.

| *White.* | *Black.* |
|---|---|
| 1. Kt-Q 4 | 1. Anything |
| 2. Q-B 3 | 2. Anything |
| 3. B-Q B 3 mate | |

### NOTICES TO CORRESPONDENTS.

Correct solutions to 943 by G. T. Stringfellow, E. Stanley Follwell (most enjoyable), and V. S. Pochin; to 944 by Rev. W. Anderson (Old Romney), and V. S. Pochin, E. Stanley Follwell (delightful), R. A. Bennett, H. Culmer, F. A. Vincent, and A. S. Olver (poor).

To 945 by A. S. Olver (exceedingly clever), H. Culmer, Streetgate (very pretty), E. S, F. A. Vincent, V. S. Pochin, and Rev. W. Anderson.

V. S. P.—The tourney will be concluded in about two months.

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve months, Post Free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX., and XL., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post free from the office (except index numbers, which are 3d. each, or post free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words .. .. .. .. .. .. .. | 2 | 6 |
| Every additional eight words .. .. .. .. | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

|---|---|---|
| Twenty-four words .. .. .. .. .. .. .. | 0 | 3 |
| For every succeeding Eight Words .. .. .. .. | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words .. .. .. .. .. .. .. .. | | 6 |
| For every succeeding Eight words .. .. .. .. | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday, to insure insertion in the following Friday's number.

**Holloway's Pills.**—Easy Digestion.—These admirable Pills cannot be too highly appreciated for the wholesome power they exert over all disorders of the stomach, liver, bowels, and kidneys. They instantaneously relieve and steadily work out a thorough cure, and in its course dispel headache, biliousness, flatulence, and depression of spirits.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—Caplatzi, Science Depot, Chenies-street, near British Museum. Established 1862.

**Telescope,** 2½in. Reflector, two eyepieces, tripod stand, in oak case, for English made Air Gun, with pump complete.—Jos Blain, Albert-square, Carlisle.

**Polishing Machine,** foot-power, all iron, cost £4 10s.; lot of tricycle and bicycle fittings, bankrupt stock. Seen by appointment. Exchange offers.—W. Smith.

**Youth's Tricycles** (6), part finished. Exchange to £1 each. Seen by appointment only. Particulars one stamp.—Address, W. Smith, Bilston-road, Wolverhampton.

"**Knowledge,**" 1—122, in exchange for good Microscope, Telescope, or Field Glass.—Address, Hugh Crichton, 11, Panmure-street, Arbroath.

Exchange 54 or 56in. **Bicycle,** Carver's hollow spoke, ball bearings, for Lancaster's Instantograph and Accessories, or offers.—Frank Perry, Mountnessing, Brentwood.

Offer wanted. Bench Drilling Machine, iron grooved wheels, chucks, drills, treadle, for model work.—A., 17, Peach-street, Queens's Park Estate, Harrow road.

Twelve **Bunsen Cells** (quarts) offered in exchange for Books on Electricity, or anything useful.—J. W. G., Albert House, Haverfordwest.

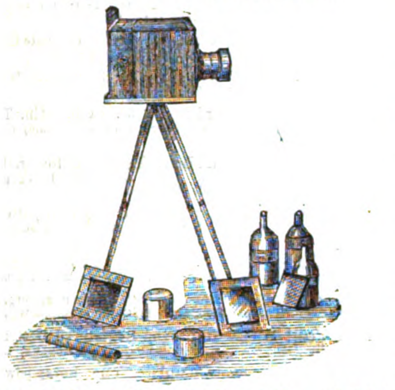
JOSEPH BUCK,
56, HOLBORN VIADUCT, E.C., and 164, WATERLOO ROAD, LONDON.

# J. THEOBALD & COMPANY'S SPECIALITIES.

## THE AMATEUR'S PHOTOGRAPHIC CAMERA.
FOR INSTANTANEOUS PHOTOGRAPHY.



As we expected, the one Advertisement inserted by us a fortnight back of this Camera has created quite a sensation, and the large number of Cameras we have sold, and the repeat orders we have received, have fully convinced us that we need have no fear but that they will—in fact, have already—become a decided success.

Many persons have written to us, saying, "I know nothing of photography, are you sure I can take good photographs without a lot of trouble?" Our answer is "Yes. Photography has undergone a complete change the last year or two, and anyone now, by simply following out the full and plain instructions we send, can take perfect photographs equal to a photographer." Others say. "But proper cameras cost £5, £7, and £10; how can you offer one as good for 15s.?" Why, because we buy everything direct from the makers that must be bought, and most of the apparatus we make up ourselves at a very trifling cost. An expensive camera has a lot of unnecessary brass screws, plated fronts, &c., which have nothing to do with the photograph, and simply makes the camera more expensive.

We give everything that is necessary, and rely on an immense sale to pay us for being content with a very small profit.

☞Please note that many cameras now advertised at 30s., 40s., and 60s. are cameras only, and without any apparatus or chemicals whatever. Ours is EVERYTHING COMPLETE.

Photography is a most fascinating art, and is now being largely practised by the gentry and nobility, and many ladies also have become quite professionals at it.

It is not only amusing, but pleasing and useful, to be able at any moment to take photographs of scenery, houses, friends, models, pet animals, seaside views, &c. Why pay a photographer 5s. 6d., 8s. 6d., and 10s. 6d. dozen for photographs, when you can take them equally well at a cost of 1s. 6d. dozen?

The Amateur's Photographic Camera No. 1 measures 6in. square, and consists of a strong well-made camera, wood body, powerful lenses, brass fittings, brass cap, focussing tube, dark shutter and slide, focussing glass, packet of dry plates, packet of sensitised papers, two bottles of developing solution, bottle gold solution, box of fixing crystals, cards for mounting, printing frame, elastic bands, glass roller, and full instructions complete. Carriage free, 15s. This apparatus will really take perfect Photographs, carte-de-visite size, indoors or outdoors.

The Amateur's Camera No. 2 is the same size, but with stronger lenses, and very superior finish throughout; also having larger supply of chemicals. Carriage free, 25s.

The Amateur Camera No. 3 is double size, being made for taking cabinet-size photographs, and consequently has double-size lenses, very superior finish, double shutter, and all other apparatus as given with the Nos. 1 and 2, but double size. Price, carriage free, 30s. This is good enough for any photographer to set up in business with.

Specimen of carte-de-visite portrait taken with the Amateur Camera by an amateur, post free, 6d.; cabinet size, 1s.

Many persons could make a good living with one of these Cameras.

Orders executed immediately, as we have several workmen making these Cameras, and no vexatious delays occur.

All orders should be sent within twenty-eight days (except from abroad), as we do not guarantee to supply them at these prices once we have made them widely known. Carriage abroad 5s. extra. Please mention the name of this Paper.

### VERY SPECIAL NOTICES.

Final Offers.

**Last few weeks of ever being able to get Field-Glasses at these prices.**

It is now nearly five years since we first began advertising our Glasses. The demand for them has been unprecedented, and from every part of the world have been received letters expressing the great satisfaction they have given. We consider now that we have made them thoroughly known to the public. They were started at prices so far below those ordinarily charged that opticians stood aghast, and, in their own interest, declared they could not be good. However, they were a great success from the very first, and now there is no one, however bigoted, who has seen one, but is full of praise. We get repeat orders again and again, and many persons order from mere recommendation. We have decided now to

CEASE ADVERTISING

these Glasses, as they are now so widely known that there is no necessity to continue spending large sums of money weekly in so advertising. Therefore, as this will probably be the last time that this offer will appear, we urge all those who are in want and desire thoroughly good Glasses at nominal prices to send at once.

## THE KENSINGTON AMATEUR

PRINTING APPARATUS.—For cards, notepaper, bill-heads, &c. Strong wooden press, assortment of type, ink, dabber, and instructions complete.

Carriage free, 2s. 9d.

Much larger sizes, 3s. 9d., 5s., 6s. 6d., 8s. 6d., 10s. 6d., 15s., 17s. 6d., 21s., and 25s.

THE RENOWNED AND FAVOURITE

## GEM FIELD-GLASSES,

which have always given such universal satisfaction. These are made in three sizes, and each Glass has six very powerful lenses, and will carry a distance of twenty-five to thirty miles. Each instrument is also fitted with sunshades, gilt mounts, and extra stout case, with strap for slinging across the shoulder, complete. Every one is guaranteed to be of the very best quality; in fact, the years we have been advertising is a sufficient guarantee that no trashy articles are ever sent out. The Glasses will be sent complete and carriage free at the following prices:—No. 1 size, having object-glasses 1⅛in diameter, 18s. 6d.; No. 2, 1⅜in. diameter, 22s.; No. 3, 1⅝in. diameter, 25s. These Glasses are equally suitable for the Theatre as for Field-Glasses, and are really marvels of power and quality throughout. We would also draw special attention to

## THE ACME FIELD-GLASS No. 2,

which is made with twelve very powerful lenses, and has a wonderful power for both long and short distances. Object-glasses are 1⅜in. diameter, and a best soft leather case, with strap complete, is also supplied. Carriage free, 37s.

## THE NEW FIELD-GLASS. — We

specially recommend these Glasses. Don't pass them by. Ever alive to the necessity of advancing on previous efforts, and never resting satisfied with what has been already accomplished, we are glad to be able to announce our manufacture of a new and improved Field-Glass. For the past five years our Optical Instruments have been before the public, and each season it has been our aim to improve on the previous year's product; and up to the present, success has ever been vouchsafed to us. This season we are able to introduce what we are sure will prove a great boon to all tourists and travellers—viz., a glass which, opening to a great length, yet closes into a very small compass. It is a well-known fact that the further away lenses can be placed from each other, the greater power and definition can be obtained; but persons have objected to carrying a cumbersome instrument to effect this purpose. Our New Glass,

## THE "VICTORIA" FIELD-GLASS,

does away with this objection altogether, for it is made with double drawers, so that the length desired is obtained without in any way making the Glass larger when closed than any ordinary single-drawer Field-Glass. When closed the Glass is only 3½ inches high. Is has six lenses of the very best quality, and the object-glasses measure over 1⅜in. diameter. The body is morocco-covered and fitted with sunshades complete, in strong velvet-lined case, with handle and strap. This Glass is extremely powerful and readily carries twenty-five miles. Owing to its small size and special adaptability of its lenses, it would do equally well for the opera as for long distances. Each Glass is engraved "The Victoria," and bears our name, without which none are genuine. We offer them for twenty-eight days, carriage free for 50s. We do not guarantee to supply any after twenty-eight days at this price, as, owing to an immense strike amongst the optical workmen, we can only sell what we have manufactured during the winter at these prices.

## THE "KENSINGTON" FIELD-GLASS,

Precisely the same kind and size Instrument but with twelve lenses, giving an immense increase of power. Carriage free, £3 3s. Carriage to all foreign places 5s. extra.

The leading London and Provincial Press speak in the highest terms of our Glasses.

"Exceedingly cheap."—*Christian World*.

"A thoroughly well made and powerful Glass."—*The Baptist*.

"Gave us every satisfaction. Wonderfully cheap."—*Church Times*.

"Nothing better can be bought for the same money."—*Amateur Work*.

"I can thoroughly recommend them."—*Sylvia's Journal*.

"Carlton Club, Pall Mall.

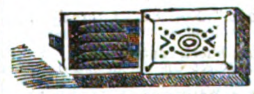
"Gentlemen,—I am much pleased with your Acme Field Glass No. 2. It is marvellous to me how so perfect a glass can be made at such a small price as 37s., possessing such very high powers through its splendid lenses.—Yours obediently,

"R. A. H. HIRST (Major)."

As an inducement to persons to purchase at once, we have arranged a Grand Distribution of Prizes, which will be fairly distributed amongst those persons buying our Glasses within the next twenty-eight days. For these

VALUABLE PRIZES

no charge whatever is made. Every person sending for an Instrument will received a free ticket. The prizes are nearly 300 in number, and are of the value of five guineas, three guineas, and one guinea, &c. For further particulars, see Catalogue. Tickets will be given as follows:—With every Gem, one ticket; No. 2 Acme Field-Glass, two tickets. All persons must mention the name of this Journal, otherwise no ticket will be sent.



## THE MAGIC

CIGAR CASE. Offered to a friend full of Choice Cigars, but directly he attempts to take one they all vanish. Post free, 14 stamps; or real leather cases, 2s. 2d. Large size, 3s. 3d.

## THE KENSINGTON SCREW

STEAMER. Entirely of metal. Propelled through the water by steam for half an hour at each operation. 9½in. long. Painted in two colours, and with boiler, lamp, steam-pipe, fan wheel, screw, and rudder complete. Post free, 1s. 9d. Larger sizes, 5s. 6d., 6s. 6d., 11s., and 13s.

## THE RHINE HARP.—Over 15,000 of

these Harps have been sold in England alone. We had one order from a wholesale house, they would take all we could possibly send them within one week, the demand was so great for them. We offer the remainder of our last consignment from Germany at the low price of 8s. 6d., carriage free. Customers wishing for one should send at once, as, in consequence of the maker altering his prices, we have decided not to order any more.

They are 18in. high and 12in. wide. Each has nineteen strings (2½ octaves) stretched over an iron frame, the woodwork is beautifully polished, and the Instrument finished throughout in the best style. These Instruments can be readily learnt in a few easy lessons by anyone. They are played with the fingers the same as an ordinary harp, giving forth sufficient sound, &c., to fill a large room, or can be played as softly as required. We fee sure that in thousands of English homes the "RHINE" HARP will find a hearty welcome.

We give with each Harp the fullest instructions, and so that a child, in a few minutes, could really play a tune, the music being so arranged by us as to present no obstacle. To give everyone a chance of possessing one, we will send one Harp, with fifty pieces music, tuning-key, and full instructions, carriage free, for 8s. 6d. If two are taken at a time, 1s. each less; if three, 1s. 6d. each less. We will not guarantee to supply any after twenty-eight days at these prices.

## POWERFUL STRONG

BRACE and BITS.—A large consignment to be sold immediately regardless of cost With four Bits free, 1s. 9d.; six bits, 2s. 3d.; twelve Bits 3s. 9d.

## THE KENSINGTON SECRET

SWORD-CANES. — Invaluable for self-defence. Have the appearance of an ordinary walking-stick, but each contains secret steel sword. Carriage free, 1s. 9d., 2s. 3d., 2s. 9d. 3s. 6d.; better quality, 4s. 6d.; very superior, with secret spring, 5s. 6d., 7s. 9d., 9s. 9d., 12s. 6d., 15s.

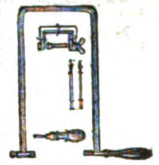
## THE CHAMPION AMERICAN

WRESTLERS. — Selling by thousands. These amusing figures jump about and start up and down with lifelike reality, first one gaining the ascendancy, and then the other. Endless fun. Post free, 10 stamps. Best quality, 20 stamps.

## THE MAGIC FOUNTAIN PIN. — AN

elegant Gold-plated Stag's Head Breast-pin. Can be worn by either lady or gentleman. Diffuses sprays of delightful perfume at the will of the wearer. 50,000 sold. Post free, 14 stamps. Magic Fountain Ring, 14 stamps.

## AMATEUR'S FRET-SAW



OUTFIT.—On card complete as shown. Comprising good fret-saw frame, assortment of saws, iron cramp, files, bradawl, and patterns complete.

Carriage free, 3s.

Nickel plated, 4s. 6d.

Better quality, with drill and bits, 5s. 6d.

Patterns, 2s. dozen.

Saws, 4d. dozen; files, 1s. 6d. dozen; drill and bits, 1s. dozen.

## THE KENSINGTON MUSICAL TOP

A most wonderful novelty. Directly this top is spun it commences playing music, owing to musical notes inside. Post free, 16 stamps.

## A FISHY BARGAIN.

Superior **Pebble Spectacles,** free on focus and order for 5s. 6d.—E. Scott, Watchmaker, Ripon Shops, Hedon-road, Hull.

Devonshire **Cream** from the Separator, solid, travels well, keeps in perfect condition a week, ½lb., 1s. 6d.

**Fresh Butter** from the Cream, as above, 2½lb., 3s. 9d.—G. Bull, Manor Farm, Martock, Somerset.

Every Mechanic should use the **Link Spanner.** Bauer's patent. Sample, 5in., 1s 11d., post free. All sizes up to 24in. in stock.—The Patent Inventions Co., 169, Manor-street, High-street, Clapham, London, S.W.

**Bamboo Fishing Rods,** 10 or 6-joint, 1s., 15 feet ; 5-joint, 9½d., carriage 3d.—Bristow and Co., Hull.

"**English Mechanic,**" Nos. 896–1,040, 5½ Vols., complete, clean, 10s.—Rudd, 261, Dunbarton-road, Glasgow.

**Gregorian,** by James Short, untouched, 1740, 20s. Achromatic Telescope, 1½in. Object Glass by Chamberlain, rack and pinion, 20s. Portable Microscope, by Steward, mahogany box, 15s., or offers.—Forgan, 3, Warriston-crescent, Edinburgh

**Gas Engine,** bargain, 1-man, off Dorrington's castings, built for exhibition, no further use for it, cylinder, 4½ dia.—Wm. Ainsworth, *Gazette* Office, Accrington.

First-class highly finished Horizontal **Steam Engine,** cylinder (mahogany cover), 4¾in. dia., 9in. stroke, steel piston rod, wrought iron cross head, 4 motion bars, turned flywheel, polished crank plate, £16.—Photo, Old Rectory Clock Works, Monkwearmouth, Sunderland.

**Bicycle,** 54in., nickel-plated, hollow forks, Æolus ball bearings, a bargain. £7 10s.—118, Richmond-road, Dalston.

New ½-horse Horizontal **Engine and Boiler,** with pump and fittings, complete, £2 15s. lot.—Apply, 12, Gt. Union-street, Drypool, Hull. Boiler pressure, 45lb.

Horizontal **Engine,** nearly finished, cylinders, 2⅜ bore, price 55s. Worth double.—Jas. Hunter, Daisy-hill, Chester-le-street.

Model **Vertical Engine,** 1⅜-inch bore, 3-inch stroke, £5.—R. M. T., 111, Bedford-road, Clapham.

**Gas Engine,** ½ H.P., "Otto," by Crossly, first-rate condition.—Seen at work, 98, King's-road, Camden-road, N.W.

Achromatic Pocket **Telescope,** extra astronomical eyepiece, perfect, 6s. Cost double.—Buffham, Connaught-road, Walthamstow.

**Voltmeter,** to 30 Volts., 10s. 6d.. Ammeters, 20 ampères, 5s. 6d.—W. A. Walton, London-road, Gloucester.

**Oval Chuck,** splendid, in good condition, for sale cheap, suitable for lathes, 5in. upwards.—J. G. Moon.

Two **Cone Plates,** with standard, suitable for 6in. or 7in. lathe, taking from ½in. to 2½in. in diameter.—J. G. Moon.

**Lathe Bed,** nicely planed, with standards, 6ft. long suitable for 6in. centres ; also turned flywheel.—J. G. Moon.

**Surface Plate,** 16in. by 10in., sides planed, for sale, cheap.—J. G. Moon, 2, St. Joseph's Villas, Sulgrave-road, Hammersmith, W.

**Gas-Engine,** 3-man, Barker's Patent Universal, good as new, £28. All my extra fittings.

Also Patent **Band-Saw Machine,** on stand, two saws, hand or power.—10, Darby-road, Folkestone.

**Standard Ohms,** 2s. 6d. each. Delicate Galvanometers, astatic, 5s.—S. Bottone has a few for Sale.

**Am-meters,** indicating up to 8 ampères, 5s. Voltmeters, 5s. Model Electro-Motors, 5s.—S. Bottone.

**Wheatstone's Bridges,** 5s. each. 6in. Tangent Galvanometers, glass shades, 10s.—S. Bottone, Stanley-road, Carshalton.

**Incandescent Carbon Lamps,** low resistance, 3s. each. Fairy Lamps, 3s. 6d. Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders,** new pattern, best in the Trade, 12s. dozen. Sample, post free, 1s. 3d.—Todd, as above.

**New Time.**—Alter your Clocks and Watches. Twelve Sets of figures, with instructions, 6d.—Wheeler, Preston.

**Water Motors,** for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings.**—Improved Registered Designs ; sets 4in., 3s. ; 6in., 4s. ; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors.**—Complete one horse-power, £9. Half, £6 ; Quarter, £4 ; Eighth, £3.—Thomas Wheeler, Preston.

26 Vols. "**English Mechanic,**" 3s. each. 6 Vols. "Popular Educator," 15s ; 4 Vols. "Technical Educator," 10s., clean, well bound.—Walker, 54, Grove-street, Liverpool.

**Anvil,** good as new, 1½ cwt., price 18s. Also Leg Vice, price 7s. 6d. Driving Wheel, suitable for lathe, weight about 50lb. Price 5s.—Chas. Inwood, Blackpool-street, Burton-on-Trent.

**Bicycles, Tricycles, and Fittings** ; Perambulators and Fittings ; cheapest on record ; agents supplied.—33, Porthope-road, Birmingham.

**Drawing** of Coil Electric Machine, 4s. Power Hammer, Slotting Machine, Piston, 2s. Oxford Frame Machine, 3s.—E. Dale, Christchurch.

**Tic.**—This excruciating agony completely cured by Thomas Palmer's new remedy, and health and strength restored, 13 stamps.—St. Helen's, Auckland, Durham.

**Lathe Tool Holders,** 3s. Tools, 4d. each. Much handier and cheaper than ordinary tools.—S. Beeching, Mareham-le-Fen, Boston.

**Engine,** Vertical, 2-horse, £6. Semi-portable Boiler, 3-horse, £9.—79, Dudley-road, West Bromwich.

5¼in. Metal Newtonian **Reflector,** 6ft. focus, 50s Galvanised Iron Tube, 7s. 6d.—Prideaux, Wellington, Somerset.

Plain **Photographic Backgrounds,** in Flatted Oil on rollers, 7s. each.—Samples of H. Southgate, Basingstoke.

100-light **Dynamo,** new ; two 30-light Machines, Several smaller ones, Siemens Armature.—Warne.

25-light original Gramme **Dynamo,** warranted. Particulars, testimonials ; all letters answered.—Warne, 39, St. John-street-road, E.C.

**Serrin Arc Lamp** for sale, cheap, £3, in good order.—R. Huffett, 86, Richmond-villas, Huntingdon-road, Cambridge.

Self-acting **Electric Model** of Steam Hammer, 200 blows per minute, 12s. 6d.—G. Bowron, 97, Crawford-street, W.

**Steam Canoes,** from £30 ; also Engines, Boilers, and propellers for same ; state requirements.—Chinnall, Eastville, Bristol.

For sale, 48in. **Bicycle,** with bent handle, bright, with lamp, bell, keys, oilcan, &c. tyres good as new, £3 3s.—E. Boyce, Flanshaw, near Wakefield.

Self-acting **Organ,** twenty-eight tunes, seven barrels, landscape moving trains, balloons ; sale or exchange.—Davidson, 9, Gladesmore-road, Stamford Hill, N.

**Microscope Objectives** for sale, cheap ; a 1in., 2in., ½in., 4-10th, ¼in., 1-6th, ⅛th, and 1-12th immersion, together or separate.—E. S., 105, Myddleton-road, Hornsey.

Sale Columns from May 8.—**Stanley's Recipes.** Present terms—one, 7d. ; three, 13d. ; six, 19d. ; twelve, 31d.

**Eno's Fruit-Salt.**—Why pay six times its cost? Receipe (warranted genuine) 7d.—Stanley, 119, Manchester-road. Poplar.

**Electro Motor,** free, 2s. 6d., with Battery 3s. 6d. Model Engine, 1s., fee. Not approved, money returned.—Below.

**Batteries.**—Bunsen's, Daniell's, Bichromate, 1s. each, in box 1s. 6d., post free.—G. Hailey, Novelty Stores, Seaforth, Liverpool.

**Electric Indicators, Bells, &c.** Royal Letters Patent. Cheapest in market.—Halbert Works, 27, Penton-place, Pentonville-hill.

**Lathes.**—New designs, best workmanship, unequalled finish ; own make. Note Prices.—W. Bundy, 62, Holborn-viaduct, London.

4½in. centre, 4ft. bed, **Screw-Cutting,** chain treadle, hollow spindle, double geared, 22 wheels, face plate, &c. ; weight 6 cwt. ; £17.—Bundy.

5in. centre, 5ft. bed, **Screw-Cutting,** double-geared, improved slide-rest to turn any angle and indexed, 22 wheels, tool board, anti-friction treadle, 4 speeds, £.2

6in. centre, 6ft. bed, same as above for treadle, weight 13 cwt., £27 ; surfacing £3 10s. extra.—Bundy.

6in. centre, 6ft. bed, **Screw-Cutting Lathe,** for power, 11 cwt., £24 ; surfacing £26.—Bundy.

Double-geared **Foot Lathes,** straight beds, with eccentric rests and chain treadle (slide rests extra), as below. 5in. centre 5ft. bed, 9 cwt., £14 ; 6in. centre, 6ft. bed., £16 10s.—Bundy.

**Makers** of all other sizes and descriptions of Lathes and Machine Tools.

Compound **Slide-Rests,** 5in., £3 10s. ; 6in., £4 10s. ; 7in., £5 ; 8in., £5 10s. ; 9in., £7 10s. ; 10in. £9 ; 12in., £11 10s. Chucks, 7s. per inch. Bell chucks, handrests, headstocks.

Note Name.—**W. Bundy and Co.,** 62, Holborn Viaduct, London.

Beautiful rare **Orchises,** in bloom. Bee Orchis, 1s. each ; Butterfly Orchis, 9d. each ; Fly Orchis, 8d. each, carriage free.—John Burns, Fellside, Kendal, Westmoreland.

## TOOLS AND CUTTER-BARS.

(*Concluded from page* 358.)

INSIDE WORK.—For this the bars and cutters hitherto described are unsuitable, and their place is occupied by variously-arranged side tools, either themselves bent or placed in holders, which will present them to the work at the proper angle. One such bar, by Taylor, of Birmingham, is shown at Fig. 48, and the tool to fit it is given at the side at B to a reduced scale. Here the smith has to bend up the end of a round steel bar, which is then filed to the desired cutting angle with sufficient clearance for the work in hand. The tool is prevented from revolving in the bar by a flat filed on its upper side, against which the end of a clamping screw presses; but this does not prevent the cutter from being drawn out or thrust in to a limited extent, according to the depth of the hole to be cut. Another bar is shown in Fig. 49, as made by Hines, of Norwich, to hold small, straight bits of steel requiring no forging or bending and no clamping screw. A small and slightly conical mortice is drilled and filed near the end of the bar, and at right angles to it, and a very small bit of steel is filed up to fit it accurately, and to project very slightly. This is also shaped for clearance, and made more or less keen, according to the metal on which it is to be used. To prevent the necessity for so long an end beyond the squared part, which is an element of weakness, and only needed for a deep hole, the shank is now often made as a separate piece, drilled and sawn to receive the round bar like that of W. S. Brown, already illustrated. This is a great improvement, because only so much of the round bar need project as is actually necessary for the particular hole to be bored, doing away with all unnecessary springiness. To enable the cut to be taken quite to the bottom of a hole which does not go through the work, the cutters are sometimes put in at an angle, such as to cause their projection beyond the end of the bar. This, called a Cawdron bar by Mr. Hines, is a still further improvement, and top rake can be given by filing the little mortise at a suitable angle. The very small cutters are a little difficult to fit, but need no clamping-screw to hold them—a very great advantage. The bars are in sets of three, and are very useful. It is plain that the only choice before us is between such tools as Fig. 48—i.e., bent ones, or straight tools held so as to project on the side of a suitable bar, the latter for very heavy cuts usually needing the security of a clamping-screw. The theory of cutting tools is the same whether for inside or solid work. There will be the surface of the work and the shoulder; but the former is, of course, concave instead of convex. The leading edge in this case will be the one that has to deal with the shoulder, and which has to take the big share of work, yet here the amateur is generally at fault, as the end of the tool frequently has absolutely no clearance, and very little cutting power. At A, Fig. 48, the tool is made quite sharp, but at B it is quite blunt, and the consequence is that it needs great force to push it forward, and the work done is rough and uneven. Whether round or not, consider it a double-edged tool, and the proper way to sharpen it will appear at once, whether it is a solid tool or a short cutter held in a bar. Suppose the tool held in a Haydon bar as before (Fig. 50), and travelling forward in the direction of the arrow; *a* would be its leading, and *b* its following edge. Bend it instead, as shown, remembering that the shank of the tool or the bar merely acts as a handle, and the principle of the cutting edges will be at once apparent; rounding off the point will bring it to the usual form of an inside tool (Fig. 50 B). It may be as well here to add a word in relation to the actual work of hollowing out a casting, as, for instance, a cup chuck. The skin is intensely hard, and if a nicely sharpened tool is placed to cut it without previous preparation, away goes its edge forthwith. To prevent this very undesirable consummation, take an old file and so hold it while the work is revolving as to clear a bevel and expose the bright metal. Then place the tool so that its edges only meet this clean metal, and they get under the hard skin, which then comes away on the first shaving, unless the chilled part of the metal penetrates deeply, or the cut is very light. This will depend a good deal upon the founder. I have had iron so hard that I could do nothing with it, while other castings, specially intended for the lathe, often prove of excellent quality, scarcely blunting at all a well-hardened tool. In boring small holes the chief difficulty will probably arise from the rubbing of the tool below the edge, as the setting of the tool is a little more difficult than for work of large size. In this case, therefore, it is usual to give rather more clearance, or to set the tool very slightly above the centre. In adding to the clearance, it is better to round off the tool below the cutting edge to nearly the intended curve of the inside of the work. But, in practice, small work, which does not readily admit a well-shaped tool, is drilled, and not bored, especially as the twist-drills now used make such beautiful and true work. And these same drills show pretty fairly what should be the test of a well-ground and correctly placed tool—viz., a clean shaving. When new, and employed upon metal of good quality, two equal shavings, often of considerable length, will emerge as the drill descends into its hole. A cutter, right in edge and position, will bring away a clean shaving, bright and

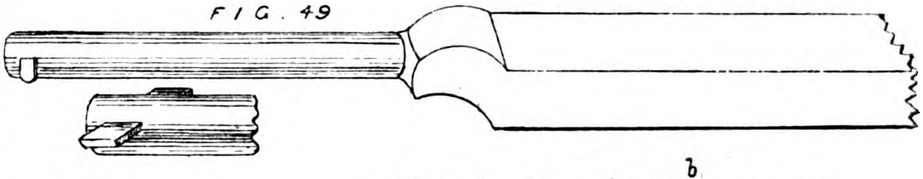

FIG. 50

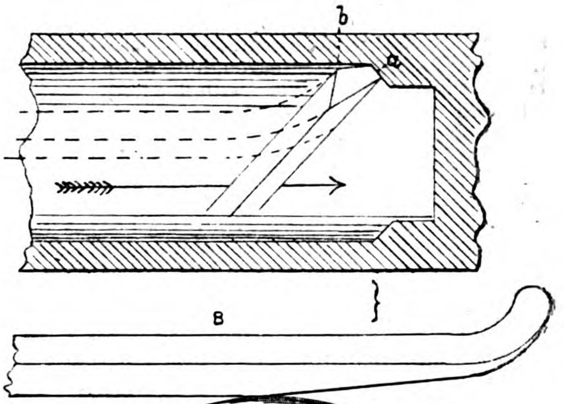

FIG. 51

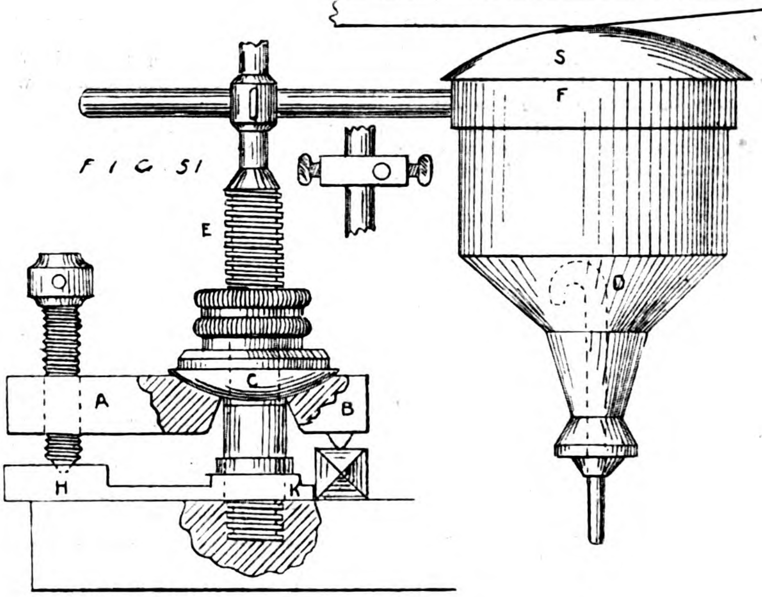

polished on the outer side, if a lubricant is used. That side having been fairly cut, the inside is, of course, crushed across, as it has curled up, and is, consequently, quite rough.
